This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

center of oscillation of the swinging frame determines the radius of the circle of which the felly is an arc.

Felt. 1. (*Fabric.*) Fur and wool fibers have barbed surfaces inclined from the root towards their tips. Under the influence of friction and heat these barbs spread out from the main fiber, and, like the tendrils of a plant, catch hold of other fibers and cling to them. When a mass of such fibers are disposed in all directions, they readily interlock and consolidate into a compact fabric. As these barbs all incline in one direction, the fibers can readily work into a mass of fibers, partially felted, but-end foremost. This is called *sizing*, and is produced in napping hats.

Felt probably preceded woven fabrics. In Central Asia, the home of the argali, from whence the domestic sheep has probably sprung, the clothing and tents of the people are yet, and have been since the first recorded times, felted fabrics. The latticed huts referred to by Herodotus and Æschylus are covered with felt, of which also the flapping screen which answers for a door is made. See WAGON. Marco Polo (thirteenth century) describes them fully. Klaproth describes them as of goat's hair (see HAIRCLOTH), and having a shaggy villus on the outside. The Chinese traveler, Chi-fa-hian, who visited India in the fourth century, describes the people of Chen-chen, who lived about the Lake of Lob, as wearing dresses of Chinese cut, but made of felt. Felt covered the funeral pile of Hephæstion, whose obsequies were so splendidly celebrated by Alexander; Xenophon says that felt was used to cover chairs and couches; the Medes also used felt for sacks.

The word *fell* is allied to the Greek *pilos* and Latin *pilus*, from a root word which means to *compress*. The Greek word *pilotos* — felted — comes strangely near the English *pilot*-cloth in name and meaning, not but that the latter is woven before being thickened by the act of compression (Latin, *cogo, coactus*, whence *coactilis*).

> "Lanæ et per se coactæ vestem ficiunt."
>
> PLINY.

The principal use of felt among the Greeks and Romans was in the manufacture of caps and hats. (See HAT.) The art of felting no doubt passed from Central Asia into Greece. In the time of Aristotle, besides the felt hats (*petasi*), the helmets were lined with felt (*pilos*) or sponge.

The mantles of Circassia and Phrygia to this day are heavy, stiff, and rain-proof. Colonel Leake describes a postilion's dress in Phrygia as a cloak of white camel's hair half an inch thick and stiff enough to stand alone when set on the ground. It had neither sleeves nor hood, but holes for the hand and projections like wings on the shoulders to turn off the rain.

The Armenians of Schamachi lead a nomadic life in movable huts constructed of wicker-work covered with felt, and with mats made of reed-grass.

The Nogai Tartars of the Caspian have similar shelters.

The hatters attribute the art of felting to Clement. The hatters are a very modern guild, and cannot antedate their order beyond the year 1400.

Dr. Hooke lectured on felt-making before the Royal Society, 1666. — PEPYS.

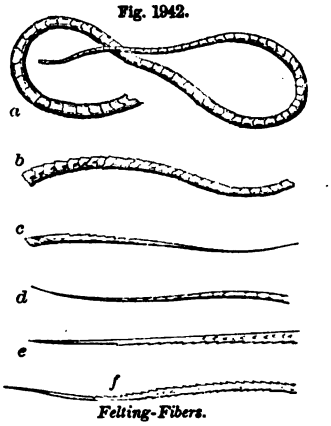
The mechanical features of the operation of felting are derived from the jagged character of the edges of some animal fibers, which enables them to pass in one direction, that is, root first, but opposes their withdrawal. The most familiar illustration of this feature is an awn of barley, a beard of wheat, or a head of grass of some kinds. These, as we all know, when introduced but-first between the wrist and the sleeve, will crawl up the arm and strongly oppose withdrawal. The teeth are presented towards the point, and resist a force applied from that direction.

If we take a human hair, hold it fast by the root-end, and draw it gently between the finger and thumb, it passes smoothly and without sensible interruption; but if we reverse the direction of motion, a sensible crepitation is experienced. If we gently press a hair between the finger and thumb, and give it a rolling motion, it will advance root first, whatever may be the position of the root in respect to the two rubbing surfaces. A fiber of wool operates in the same way, moving root first; so do the hairs which are adapted for felting when similarly treated.

The jagged structure is visible in the beard of wheat and barley, and the microscope reveals it in the hair and wool referred to.

It would be interesting to introduce various other examples of hair and wool, as seen under the microscope, but our limits forbid. *a*, in the illustration, shows the appearance under a microscope of a fiber of Saxony lamb's wool somewhat less than $\frac{1}{1000}$ of an inch in diameter. *f* shows the appearance of rabbit-hair under the microscope, and *b* beaver-down, which has a diameter of about $\frac{1}{2000}$ of an inch. *c*, *d*, *e*, show musquash, nutria, and hare's fur. They all show the jagged edge which confers upon them the characteristic felting quality.

Fig. 1942.



Felting-Fibers.

Wool in the yolk, with the natural grease (*suint*) adhering to it, will not felt, because in this state the asperities of the fiber are filled and smoothed over, just as oil destroys the action of very fine files. Fine wool that has been scoured has strong tendency to mat or felt together, and must be oiled to enable it to be carded and spun successfully.

The hair of rabbits, hares, and some other animals, is used in Russia as a felt foundation for bowls, dishes, plates, etc. It is brought to shape and then varnished; when complete, the utensil resembles papier-maché or varnished leather, and is light and durable.

English patent 1,403 of 1862 cites the use of the silky down of *typha* or bulrush. The down is separated from the seeds by a willowing process and blown over into a chamber. It is mixed with one third or half the quantity of rabbit's hair, and worked by the usual processes into hats, caps, and fabrics; or mixed with silk, wool, cotton, or flax to form a fabric for shoe-soles, paper, etc.; or mixed with caoutchouc or gutta-percha for bands, belts, carriage-fitting, accouterments, pipes; as a substitute for cork, book-covers, etc.

The uses of felt are various; among them may be cited the following: —

Digitized by Google

Among the Asiatics: cloth, hats, carpets, tent-coverings, socks.

In the United States and Europe, for domestic purposes: cloth, clothing, socks, slippers, boot and shoe soles and insoles, hats, caps, gloves, carpets, and table-covers.

Surgeons' bandages and saddle-cloths.

Mechanical: clothing for steam-boilers and cylinders; deadening for walls and floors; non-conductors for kilns and refrigerators; roofing charged with bitumen or other water-repellant; steam-packing; lining between the planking and copper-sheathing of ships; polishing-wheels; hammers of pianos; elastic blankets for printing-presses; covers of books.

2. The felted cloth on which paper is couched and carried in the paper-making machine. The cloth on which the paper is couched from the *making* cylinder is known as the *making* felt. Others as *carrying* felts, *first* felt, *second* felt, etc. Appurtenances of the *felt* are known as felt-washers, felt-rollers, etc.

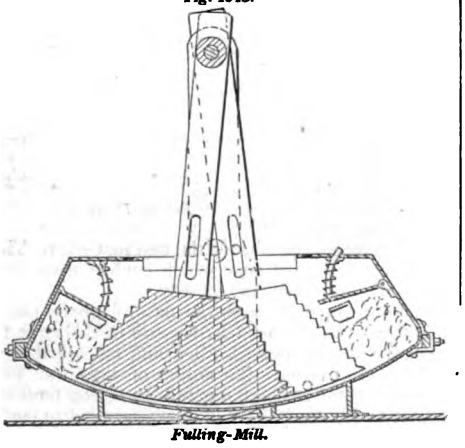
Felt-car'pet. A carpet whose fibers are not spun or woven, but are associated by the felting process.

Felt'ed Cloth. (*Fabric.*) Cloth made by felting, without spinning or weaving, was patented in England by Williams, in February, 1850.

Felt-grain. (*Wood-working.*) The grain of wood whose direction is from the pith to the bark; the direction of the medullary rays in oak and some other timber.

Felt'ing-ma-chine'. Felting-machines are of various kinds. 1. For acting upon the material in mass, as in the fulling-mill (Fig. 1943), where the cloth in a bath of soap-suds is pounded by the stock, which swings like a pendulum on its bearings above.

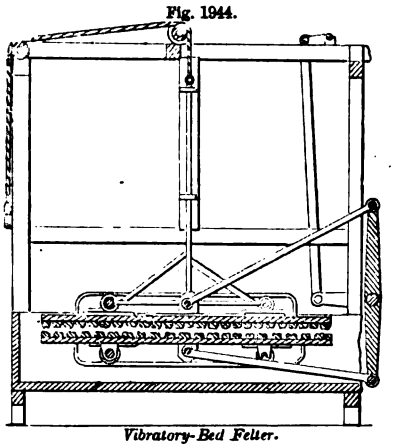
Fig. 1943.



Fulling-Mill.

2. A lower reciprocating bed mounted on grooved rollers running on tracks secured in the vat; the other bed being attached to grooved rollers that run between a double track above. The beds are worked in opposite directions by a double-action lever connecting therewith; the material placed between the beds and exposed to a rubbing action while immersed in hot water. (Fig. 1944.)

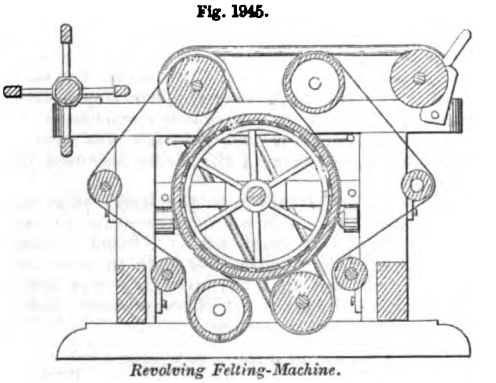
Fig. 1944.



Vibratory-Bed Felter.

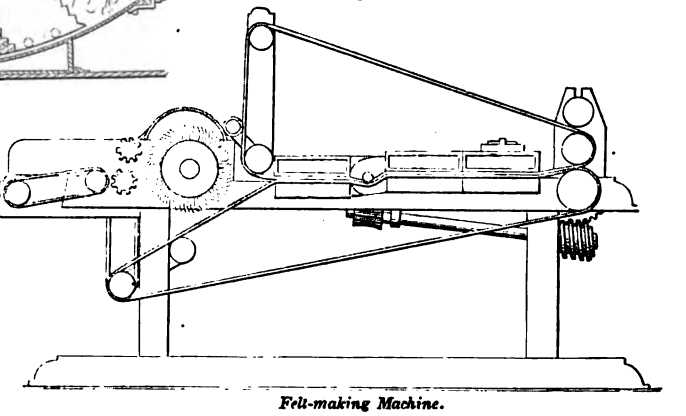
Fig. 1945 shows a form in which the main cylinder, having a cork surface, acts upon yarn or cloth carried between it and the fibrous belts which pass around steam-heated cylinders, and motive and idler rollers. Perforated pipes beneath the belts throw hot water upon them.

Fig. 1945.



Revolving Felting-Machine.

Fig. 1946.



Felt-making Machine.

In Fig. 1946 the fiber is placed on a feed-apron, passes between two fluted rollers to a card-cylinder, and is then taken between two endless aprons over

Digitized by Google

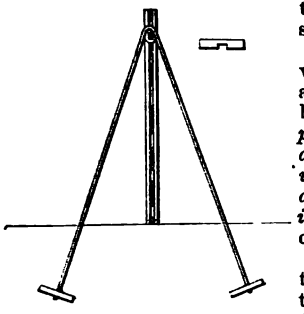
the series of tables, and beneath the longitudinally and transversely reciprocating platens. The combined heat, wet, and rubbing action consolidates the bat of fiber into a felted web.

Fe-luc'ca. (*Vessel.*) A small vessel propelled by oars and lateen sails; used in the Mediterranean and adjacent waters for coasting voyages.

Fem'er-ell. (*Carpentry.*) A louvre lantern in a roof for the escape of steam and smoke, or for ventilation.

Fence. 1. A structure on the boundary of a lot, field, or estate to keep off intruders, or act as a screen.

Fig. 1947.



Anchored Fence.

Among the varieties of fences are the *wall*, of brick or masonry; *post-and-board; post-and-rail; rail* or *worm* fence; *post-and-wire; paling*; *iron; portable; sunk* or *ha-ha; hedge.*

When stronger than most of these, the fence may rise to the dignity of a scarp, palisade, stockade, parapet, and constitute an important defensive line.

The Roman fences were four in number: —

1. The *Sepimentum naturale*, or live fence of thorn.

2. The *S. agreste*, or wooden paling interlaced with withes, or bored and strung on longitudinal rails.

3. The *S. militaire*, having a bank (*agger*), ditch (*fossa*), and *vallum*, or row of stakes on the bank.

4. The *S. fabrile*, or wall of stone, brick, adobes, or mud.

Room here can be afforded for but a bare hint of the diverse kinds.

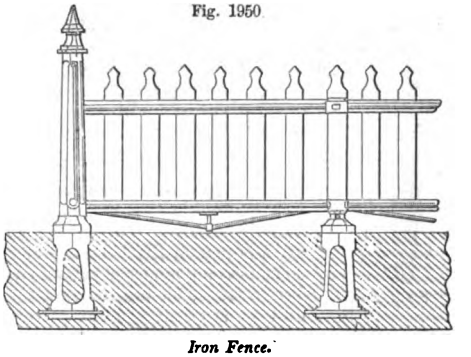
Fig. 1947 shows a mode of supporting panels of board fence standing in line; stay-rods passing over the top of the fence and being anchored below the surface.

Fig. 1948 shows a mode of hanging fence-panels to posts.

Fig. 1949 is a portable fence in which the panels rest between posts which are planted in sills and stayed by inclined bars which form buttresses.

Fig. 1950 is a more pretentious fence of iron posts set in grouting and ornamental panels.

Fig. 1950.



Iron Fence.

Fig. 1951 is a post, wire, and paling fence.

2. (*Wood-working.*) An adjustable guard-plate or edge on a gage, or on a *grooving, banding, plow, fillister*, or *reglet plane*, by which the distance of the groove from the guide-edge is regulated.

A straight edge on the work-table of a *circular, band*, or *scroll saw*, or of a *planing, molding*, or *mortising machine*. It acts as a gage and guide, and is adjustable to any required distance from the tool.

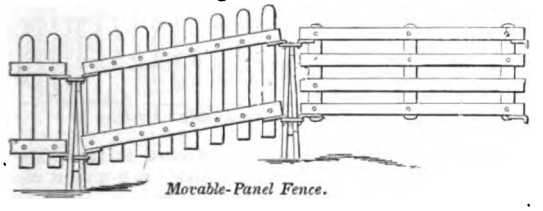
The fence may be swiveled so as to have a capacity for angular presentation of the work.

3. The arm of the hammer-spring of a gun-lock.

4. (*Locks.*) An arm or projection which enters the gates of the tumblers when they are adjusted in proper position and coincidence, and at other times prevents such movement of the dog, stump, or other obstructing member as would permit the retraction of the bolt.

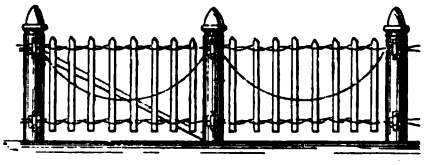
In common tumbler locks the fence forms the obstructing medium between the bolt and the tumblers, to prevent the retraction of the former when the tumbler-gates are not in coincidence.

Fig. 1948.



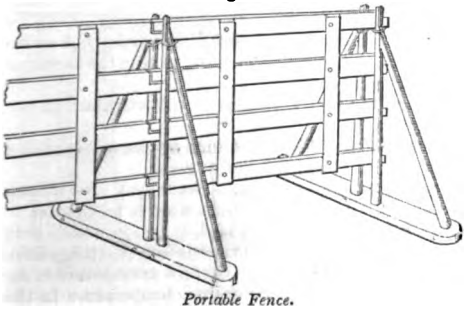
Movable-Panel Fence.

Fig. 1951.



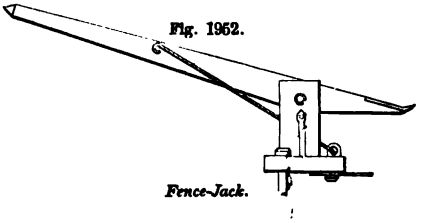
Wire and Pale Fence.

Fig. 1949.



Portable Fence.

Fig. 1952.



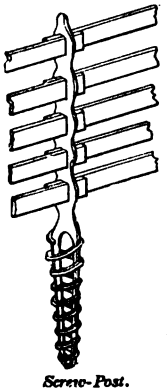
Fence-Jack.

Digitized by Google

Fence-jack. A lever jack adapted for lifting the corner or *lock* of a worm-fence in order to lay in a new bottom-rail, a fence-chunk, or a stone.

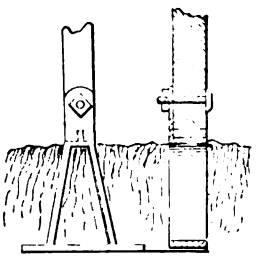
Fence-post. A piece of timber or a structure of other material, planted vertically in the ground,

Fig. 1953.



Screw-Post.

Fig. 1954.

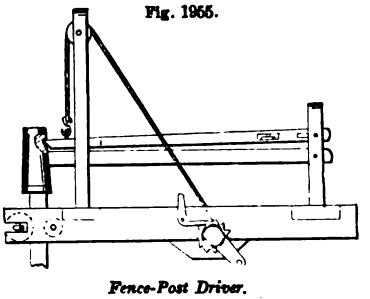


Anchor-Block and Post.

to hold panels of fence. Ingenuity has principally been exercised in contriving modes of saving timber in fences for prairie countries, and in structures as substitutes for the usual wooden posts. Two suggestive forms are shown in Figs. 1953 and 1954. One is an iron post with a spiral rib which answers as a screw for inserting it. The other is an anchor-block, to which the vertical slat of a fence is bolted.

Fence-post Driv'er. A device like a trip-hammer or pile-driver, mounted upon wheels, and used for driving fence-posts which have been previ-

Fig. 1955.

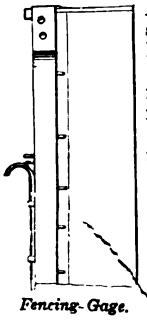


Fence-Post Driver.

ously sharpened. After the hammer attains its hight, the rope is cast off suddenly and the hammer drops.

Fenc'ing-gage. An implement to space and hold boards against a post while nailing them. The upright cleat *A* is temporarily tacked to the post, and the pegs afford rests for the lower edges of the boards.

Fig. 1956.



Fencing-Gage.

Fenc'ing-nail. A heavy nail of its class, adapted for fastening on fencing-boards.

6d, 7d, 8d, 9d, and 10d nails are made for this purpose nearly twice the weight of the common nails of these numbers.

Fend'er. A contrivance to fend off an object so as to prevent the bruising of the structure so protected.

1. An upright timber placed against the edge of a pier, dock-wall, or wharf, to prevent injury to the wall by the contact of vessels, drift, or floating ice. A *fender-pile.*

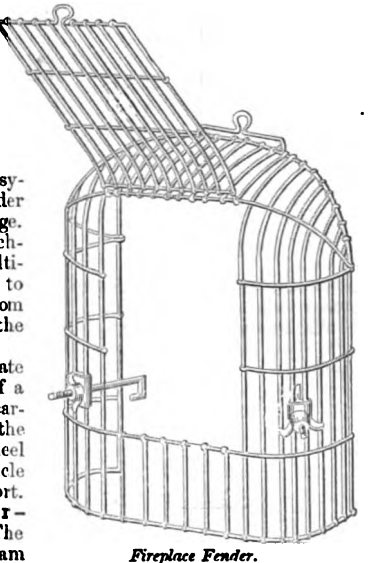
2. A mass of old rope stuffed into a heavy, open net made of rope, and placed between the sides of a vessel and the quay or pier with which it is about to collide, in order to deaden the blow and prevent injury to either of the contacting objects.

A piece of oak on a vessel's side to protect it from chafing by objects which are being hoisted aboard.

On the river steamboats of the West, poles hang overboard, being suspended from the upper guards, and answer the same purpose. Fancy rowing-boats, wherries, and man-of-war boats have fenders which hang outside the gunwale.

3. A structure in front of a fire or fireplace, to keep children or lunatics from burning themselves. In the example shown, the fender is secured by hooks to the grate-bars. In lunatic asylums the fender is a large cage.

Fig. 1957.



Fireplace Fender.

4. An attachment to a cultivator-plow to keep clods from rolling on to the young corn.

5. A rub-plate on the bed of a wagon or carriage to take the rub of the wheel when the vehicle is turning short.

Fend'er-beam. 1. The horizontal beam into which the posts of a saw-mill gate are framed at top. The fender-beam in Perley and Pattee's saw-mill at the Chaudiere Falls, Canada, is pine stock, 84 feet long and squared to 24 × 28 inches.

2. The inclined advance piece of an ice-breaker.

3. A beam suspended over a vessel's side to ward off ice and preserve the planking and sheathing of the vessel.

Fend'er-bolt. (*Shipbuilding.*) One having a large head which projects from the planking and serves as a fender to save the planks from being bruised.

Fend'er-pile. A pile fixed in front of a pier, wharf, or river wall, to ward off the blows of running ice, drift, vessels, etc.

Fend'er-post. One of the guiding stanchions of a saw-gate.

Fend'er-stop. (*Railroad Engineering.*) A structure at the end of a line of rails, to stop the carriages or engine, if needful.

Fe-nes'tra. (*Architecture.*) A window; an entrance.

Fe-nes'trai. Window-blinds or casements closed with paper or cloth, instead of glass.

Fer-ment'ing-square. (*Brewing.*) An oblong or square shallow vat in which wort is fermented.

Fer-ment'ing-vat. A tank or tun in which wort is placed to undergo the fermentation resulting from the addition of the yeast. Certain arrangements for keeping the liquid at the desired temperature in the

Digitized by Google

heat of summer or cold of winter are added in some cases.

Fer-ran'dine. A mixed stuff of silk and other materials, formerly worn. It is referred to by Pepys in his "Diary," about 1667. The word was sometimes written *furundam* or *farendone*. It probably resembled *poplin*.

Fer'ret. 1. (*Glass.*) An iron used to make the rings at the mouths of bottles, or to try the melted matter.

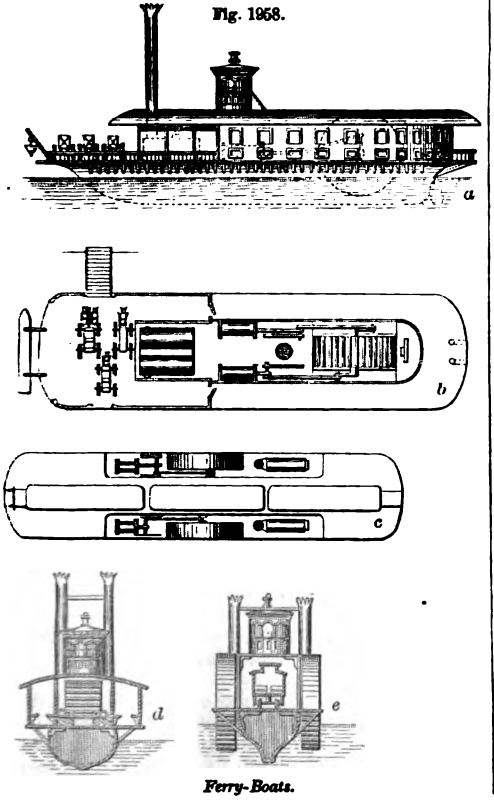
2. *Fioret*, or floss-silk.

Fer-ret'to. (*Glass.*) A preparation of copper employed in glass-coloring. It is made by placing thin sheets of copper interstratified with powdered brimstone in a crucible which is luted tight and exposed to the heat of a blast-furnace for about two hours; when cool, the copper is found to be calcined so as to be readily crumbled between the fingers; it is then pulverized and sifted for use. A superior article to the foregoing is prepared by using vitriol instead of brimstone, and exposing the crucible to the heat of the glass-furnace for three days. The old vitriol is then replaced by fresh, and the heating operation repeated six times.

Fer'ro-type. (*Photography.*) A process, so named by Hunt, which derives its name from the material of the plate (iron) on which it is taken. Plates of sheet-iron are covered with a surface of black Japan varnish. This is immersed in collodion, and after a time in the silver solution. It is then placed in the holder and exposed in the camera.

Fer'rule. 1. A short tube or thimble made slightly conical, and used to fasten the tubes in the sheet-plates of steam-boilers. Except at the point, the ferrule is a little larger than the bore of the tube, and when driven in it compresses the tube forcibly against the sides of the hole in the tube-sheet, making a steam-tight joint.

Fig. 1958.



Ferry-Boats.

2. A metallic ring or sleeve on the handle of a tool or the end of a stick, to keep the wood from splitting.

Fer'ry-boat. (*Vessel.*) A vessel for carrying passengers and freight across a river or estuary.

a, an elevation of the steam ferry-boat for ordinary travel crossing the Missouri River at Omaha.

b is a plan-view of the same, showing the single wheel amidship, the engines and boilers.

d is a transverse vertical section of the same, showing the cabins over the guards.

e is a transverse vertical section of a ferry-boat for railway-cars at La Chine, river St. Lawrence. It has side-wheels and a track amidship.

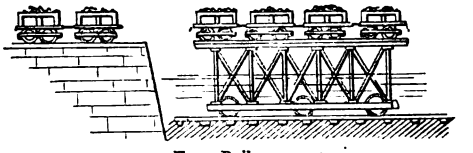
c is a plan-view of the same.

Fer'ry-bridge. A form of ferry-boat in which the railway-train moves on to the elevated deck, is transported across the water, and then lands upon the other side. Tramways forming inclined approaches are adjustable to the requirements of different stages of water in the river, or states of the tide in estuaries. The ferry-bridge which preceded the present bridge over the Susquehanna at Havre-de-Grace is a notable instance.

Ferry-bridges are also to be found in Europe, which cross by means of chains laid across the river, and chain-wheels on board rotated by an engine.

Fer'ry-rail'way. One whose track is on the bottom of the water-course and whose carriage has an elevated deck which supports the train.

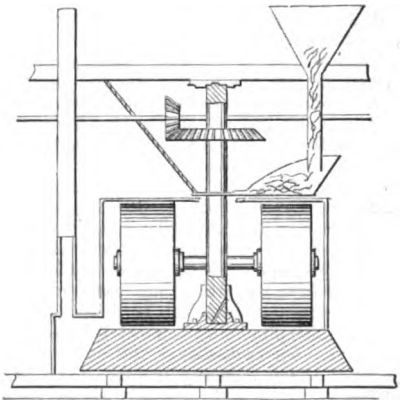
Fig. 1959.



Ferry-Railway

Fer'ti-liz'er-mill. One in which the materials are ground to powder so as to be sown from a machine. The illustration shows a Chilian mill adapted to the purpose. Phosphatic minerals, bones, and various materials are thus ground.

Fig. 1960.



Fertilizer-Mill.

Digitized by Google

Fer'ti-liz'er-sow'er. A form of seeding-machine adapted to sow granulated manures, such as dry poudrette, the phosphates, bone-dust, lime, guano, etc. It sometimes forms a machine by itself, and sometimes is an attachment to a wheat-drill; in England, also to a turnip-drill.

Fes-toon'. (*Architecture.*) An ornament like a garland. Common on friezes.

Fet'lock-boot. (*Menage.*) A protection for the fetlock and pastern of a horse. See INTERFERING-ATTACHMENTS; LEG-GUARD.

Fet'ter. A chain for the feet. See HOPPLE.

Fet'tling. 1. (*Metallurgy.*) The material, consisting of ore, cinder, and scrap-iron, mixed in varying proportions, and used in preparing the hearth of a puddling-furnace before receiving its charge of iron. *Fettle* is an old English word signifying to prepare, and corresponds to the American word *fix*. *Fixing* is the term used in the United States to signify this preparation of the hearth.

2. (*Pottery.*) The shaving and smoothing of green clay-ware to remove the appearance of seams from articles that are molded, and to smooth asperities.

Feuil-lets'. (*Diamond-cutting.*) The projecting points of the triangular facets in a *rose-cut* diamond, whose bases join those of the triangles of the central pyramid.

Fi-a'cre. A French hackney-coach.

Fi'ber-gun. A device for disintegrating vegetable fiber. Lyman's patent, No. 21,077, of 1858. Flax, hemp, jute, cane, or wood are placed in a cylinder and charged with hot water, steam, gas, or air under great pressure; the cover of the cylinder being suddenly removed, the mass is projected into a chamber where the sudden expansion of the fluid under pressure ruptures the cells and tears the fibers apart.

Attempts have been made with more or less success to use this system of rapid exclusion of the matter, under pressure of generated carbonic acid, resulting from the treatment of the material first with a caustic alkali and then with acid. See COTTONIZING FIBER.

Fi'ber, Treat'ment and Man'u-fac'ture of. See list under COTTON, FLAX, WOOL, HEMP, etc., APPLIANCES.

Fib'u-la. (*Surgical.*) A needle for sewing up wounds.

(*Masonry.*) An iron crank by which stones are fastened together.

Fid. 1. (*Nautical.*) *a.* A bar of wood or iron to support a mast upon the one beneath. It passes through a mortise in the upper mast, and rests on the trestle-trees of the head of the mast below.

b. A wooden, pointed pin used to open the strands of a rope in splicing. A similar iron instrument is a *marlinspike*, or, as used by sail-makers, a *stabber*.

2. A plug of oakum for the vent of a cannon.

Fid'dle. 1. (*Music.*) An instrument played with a bow, and having four strings, stretched over a sounding-board to give resonance, and along a neck (without frets) upon which the strings are pressed by the fingers to vary the tone. See VIOLIN.

Locusts are fiddlers. Their hind legs are the bows, and the projecting veins of their wing-covers the strings. On each side of the body in the first segment of the abdomen, just above and a little behind the thighs, is a deep cavity closed by a thin piece of skin stretched tightly across it, like a banjo-cover. When a locust begins to play, he bends the shank of one hind leg beneath the thigh, where it is lodged in a furrow designed to receive it, and then draws the leg briskly up and down several times against the projecting lateral edge and veins of the wing-cover.

From a ballad of the fourteenth century, or thereabouts, cited in Watson's "History of English Poems," occurs, —

> "Syre Ladore latte made a feste
> That was fair and honeste,
> With his lord the kynge;
> Ther was much minstralse,
> Trompus, tabors, and santre,
> Both harp and fydyllynge."

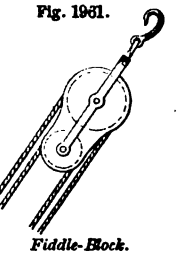
A monumental brass of the same period in St. Margaret's Church, King's Lynn, Norfolk, England, shows the musicians at a peacock feast; one has a four-stringed fiddle, another a six-stringed cithern.

2. (*Husbandry.*) A wooden bar about 11 feet long, attached by ropes at its ends to the traces of a horse, and used to drag loose straw or hay on the ground, or hay-cocks to the place of stacking. A rope or grape-vine answers very well for the latter purpose.

3. (*Nautical.*) A frame of bars and strings, to keep things from rolling off the cabin table in bad weather.

Fid'dle-block. A long block, having two sheaves of different diameters in the same plane; not as in a *double-block*, where they are in parallel planes. A *viol*-block.

Fig. 1961.



Fiddle-Block.

Fid-ham'mer. (*Nautical.*) A hammer with a face for striking and a pointed *peen* to act as a *fid*.

Field. The space visible in an optical instrument at one view. By shifting the telescope, the *field* is changed; by shifting the slip or object relatively to the object-glass of a microscope, successive parts of the object are brought within the *field*.

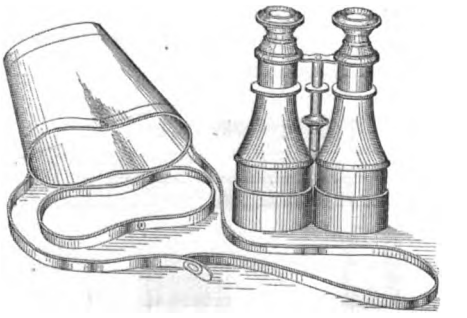
Field-bed. A folding-bed for camp use.

Field-book. The book in which the memoranda of surveys are made.

Field-der'rick. One used for stacking hay in the field. It is mounted on a sled or on a sill-piece which is anchored temporarily by stakes; otherwise it is stayed by guys.

Field-glass. 1. *a.* A binocular telescope in compact form, and having six achromatic lenses. It has a metallic body covered with morocco, and a

Fig. 1962.



Field-Glass.

sun-shade to extend over the object-glasses. It is carried in a leather case with a strap, and has a body 3¾ to 6½ inches long, the object-glasses being from 15 to 26 lines in diameter. A *lorgnette*. An *opera-glass*. A *race-glass*.

b. A small achromatic telescope, usually from 20 to 24 inches long, and having 3 to 6 draws.

2. That one of the two lenses forming the eye-piece of an astronomical telescope or compound microscope, which is nearest to the *object-glass;* the glass nearest to the eye is the *eye-glass.*

Field-gun. A light cannon designed to accompany troops in their maneuvers on the field of battle. At the commencement of the late civil war in this country, those thus denominated were the 6-pounder, weighing 885 pounds; the 12-pounder, of 1,770 pounds; a light 12-pounder of 1,220 pounds; and the 12, 24, and 32-pounder howitzers, weighing respectively 780, 1,320, and 1,820 pounds. These were all made of bronze. During the war several kinds of rifled field-guns were introduced, but only two maintained their place in the military service; the 3-inch wrought-iron rifle and the Parrott 10-pounder of 2.9-inch caliber, each nearly the weight of the bronze 6-pounder, and carrying an elongated projectile of ten pounds weight. The smooth-bores generally were withdrawn from the field during the war, with the exception of the light 12-pounder, or "Napoleon" gun.

Four smooth-bore guns and two howitzers, or six rifled or six 12-pounder guns with their carriages, caissons, forge, and battery-wagon, constitute a battery. No particular kind of breech-loading gun has been adopted in the United States Service, unless the Gatling machine-gun may be so classed. See BATTERY-GUN. Most, if not all, European governments have adopted breech-loaders of various kinds for field service.

The English use the breech-loading Armstrong gun (see ARMSTRONG-GUN) for field, fortification, and naval service.

The Prussian army uses two calibers of field-guns, 4 and 6 pounders, both rifled steel breech-loaders. The bore of the barrel extends entirely through. The breech of the 4-pounder is closed by a double wedge sliding in a horizontal slot through the barrel. The 6-pounder is closed by a plug held in place by a large steel pin. The escape of gas is prevented by a gas ring on the Broadwell plan, similar to that in a Sharp's rifle. See GAS-RING.

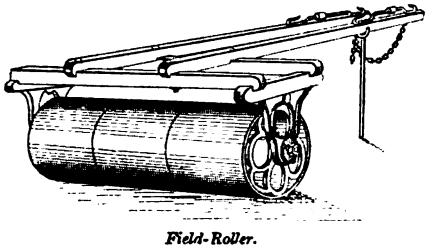
Field'ing. Exposure to the open air and sun of *malt-wash,* or *gyle* in casks, in order to promote its acetification.

Exposure to artificial heat is termed *stoving.*

Field-lens. See FIELD-GLASS, 2.

Field-roll'er. (*Husbandry.*) A wooden or iron

Fig. 1963.



Field-Roller.

cylinder, drawn over a plowed field to mash the clods and level the ground.

Field-staff. A gunner's staff for carrying a lighted match.

Field-tel'e-graph. One adapted for use in the field in military operations.

The field-telegraph of the German army consists of 140 men, 10 wagons, and 40 miles of wire for each army corps in the field. The wire is reeled out of the wagons and mounted on light poles about ten feet high, every third one being put in the ground. One eighth of the whole length of wire is insulated, and may be run along the ground.

Field-works. (*Fortification.*) These are of three kinds: —

1. Works open at the gorge: —
a. Redans, single and double.
b. Lunettes.
2. Works closed all round: —
a. Redoubts.
b. Star forts.
c. Bastioned forts.
3. *Lines,* continued or broken. See LINE.

Fife. (*Music.*) A small pipe used as a musical instrument; the usual accompaniment of the drum.

Fife-rail. (*Nautical.*) A banister on the break of a poop or around the mast of a vessel.

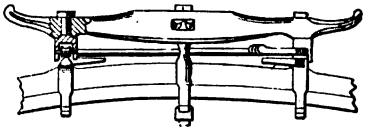
Fif-teenth'. (*Music.*) A stop of an organ tuned an octave above *principal;* two octaves above *open diapason.* See STOP.

Fifth-chain. The chain by which the single lead horse in a team of five is hitched to the end of the tongue. It is supported by chains from the harness of the leading pair.

Fifth-wheel. A wheel or segment above the fore-axle of a carriage and beneath the bed. The king-bolt is the center of oscillation, and the *fifth-wheel* forms an extended support to prevent the careening of the carriage-bed.

In the example, one part is shown in section to

Fig. 1964.



Fifth-Wheel.

exhibit the anti-friction rollers which traverse on that portion of the segment attached to the axle.

Fig'ured-fab'ric Loom. In *figure-weaving,* the cloth is ornamented with flowers and other devices. The warp is divided among a number of heddles which are operated by separate treadles, by which different colors may be concealed or brought to the surface, or made to change places according to a presented pattern. The Jacquard is the principal loom used in weaving figured fabrics. See DAMASK; JACQUARD.

Hohlfield, of Hennerndorf, in Saxony, 1711–71, invented a loom for weaving figured fabrics, the model of which is preserved in the collection of the Berlin Academy.

Fig'ure-head. (*Nautical.*) The ornament on the head or prow of a ship.

Fi'lar-mi-crom'e-ter. A micrometer having threads or wires across its field of view. It was invented by Malvasia about 1660, who applied a network of fine silver wires crossing each other at right angles, and dividing the field of the telescope into squares. See WIRE-MICROMETER.

File. A steel instrument for abrading or smoothing surfaces, and having raised cutting edges (teeth) made by the indentations of a chisel.

Files are mentioned in 1 Samuel xiii. 21, 1093 B. C. "They had a file for the mattocks and for the colters, and for the forks and for the axes, and to sharpen the goads."

Digitized by Google

Files are graded by *shape*, *size*, and *fineness* of cut; and also known by their *purpose*.

As to *shape*, the diagram (Fig. 1965) giving a series of sections will be readily understood.

a, *b*, *c*, *d*, *e*, *f*, *g*, *h*, are sections derived from the square.

i, *k*, *l*, *m*, *n*, *o*, *p*, *q*, are sections derived from the circle.

r, *s*, *t*, *v*, *w*, *x*, *y*, *z*, are sections derived from the triangle.

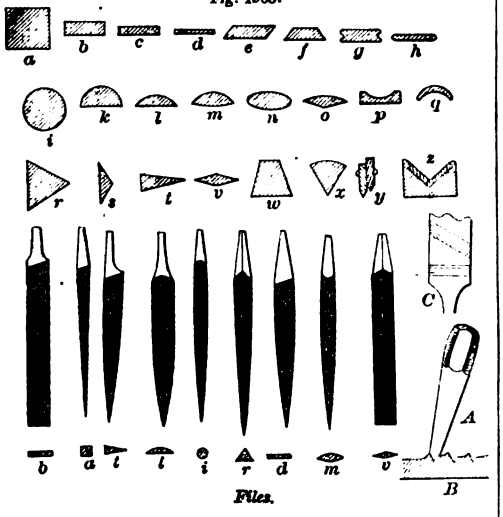
a, *square* file, parallel or taper, sometimes with a *safe* side.

b, when large, a *cotter* file; small, *verge* or *pivot* file.

c, *flat* file: when small, *pottance* file; when narrow, *pillar* file.

d, when *parallel*: *equaling*, *clock-pinion*, or *end-*

Fig. 1965.



Files.

less-screw file. When *taper*: *slitting*, *entering*, *warding*, or *barrel-hole* file.

c, *f*, *French-pivot* or *shouldering* file; *parallel V-* file.

g, *nail* file, for the finger-nails.

h, *pointing mill-saw* file, *round-edge* file.

i, *round*, *gulleting*, *rat-tail* file.

k, *frame-saw* file.

l, *half-round* file; *nicking*, *piercing*, or *round-off* file.

m, *cross* file; *double-half-round* file.

n, *oval* file.

o, *balance-wheel* or *swing-wheel* file, the convex side only cut.

p, *swaged* file, for finishing brass-moldings.

q, *curvilinear* file.

r, *triangular*, *three-square*, or *saw* file.

s, *cant* file, for filing inside angles of 120°.

t, when parallel, *banking* or *watch-pinion* file; when taper, *knife-edge* file.

v, *screw-head*, *feather-edge*, *slitting* file.

w, *valve* file.

x, *triangular-and-half-round* file.

y, *double* or *checkering* file, for gunsmiths.

z, *double*, or *pencil-sharpening* file.

Other grades of files are known by peculiarities of form not shown by section; such as:—

Taper; thinner towards the point.

Parallel; the same dimensions throughout the length.

Blunt; a grade between taper and parallel.

As to character of teeth, the classes are:—

Double-cut; having two sets of teeth crossing obliquely.

Single-cut or *float*; having but one row of teeth.

Rasp; having detached teeth made by a punch, instead of a chisel.

A (Fig. 1965) shows the position and action of the file-chisel on the blank *B*; *C* the appearance of the rows of teeth. The lower row should, however, have been shown as not quite squarely across the face of the file.

As to relative fineness of teeth:—

Rough-cut.	Second-cut.
Middle-cut.	Smooth.
Bastard.	Superfine or dead smooth.

Approximate number of cuts in an inch of files:—

Length of File in Inches.	4.	6.	8.	12.	16.	20.
Rough . . .	56	52	44	40	28	21
Bastard . . .	76	64	56	48	44	34
Smooth . . .	112	83	72	72	64	56
Superfine . .	216	144	112	88	76	64

See any in the following list, under their alphabetical heads:—

Angular-file.	Joint-file.
Arm-file.	Key-file.
Balance-wheel file.	Knife-file.
Barrel-file.	Lock-file.
Bastard-file.	Marble-workers' file.
Blunt-file.	Middle-cut file.
Bow-file.	Molding-file.
Bread-rasp.	Nail-file.
Cabinet-file.	Nicking-file.
Cant-file.	Oval file.
Carlet.	Parallel-file.
Checkering-file.	Parting-tool.
Circular-file.	Perforated file.
Cobler.	Piercing-file.
Concavo-convex file.	Pillar-file.
Cotter-file.	Pinion-file.
Cross-file.	Pivot-file.
Cutting-file.	Pottance-file.
Dead-smooth file.	Quannet.
Dental-file.	Rasp.
Double-file.	Rasp-cutting machine.
Double-cut file.	Rasper.
Double half-round file.	Rasp. Mechanical
Double-tang file.	Rat-tail file.
Dovetail-file.	Riffler.
Entering-file.	Rough-file.
Equaling-file.	Round-file.
Feather-edge file.	Round-edge file.
File-blank.	Round-off file.
File-blanks. Rolling	Rubber-file.
File-carrier.	Safe-edge file.
File-chisel.	Saw-file.
File-cleaner.	Saw-filing machine.
File-cutting machine.	Second-cut file.
File-sharpening.	Screw-head file.
File-stripper.	Shouldering-file.
Filing-block.	Single-cut file.
Filing-machine.	Slitting-file.
Filings-separator.	Smooth-file.
Flat-file.	Square-file.

Valve-file.
Verge-file.
Warding-file.
Watchmakers' file (varieties, see WATCHMAKERS' FILES).

The sculptor's file is known as a *riffler*, and is curved in various forms. Hiram Powers's file is perforated to allow escape of plaster or marble-dust.

The method of handling the chisel depends in great measure on the kind of tooth to be cut. The file is held to its place on the leaden anvil by means of a leathern strap passing over each end of the file, and then under the feet of the workman in the manner of stirrups. At every blow of the hammer the chisel is made to cut a tooth, and the blows follow each other in rapid succession, the workman after every blow advancing the chisel forward by a slight movement. The chisel forms a number of angular grooves parallel to each other, the tooth being formed by the metal raised between every two grooves. As the work proceeds, he shifts the file forward by loosening his tread upon the straps. When one surface is covered with single cuts, he proceeds, in double-cut files, to add a second row of teeth, making them cross the former obliquely.

The files are next hardened, unless they are to be used upon wood, ivory, and other soft substances; such files admit of being sharpened up with a hand-file. Some of the curved files used by sculptors and die-sinkers are made of iron and case-hardened.

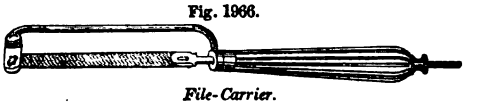
Mr. Holtzapffel describes the operation of cutting in the following terms: "The first cut is made at the point of the file; the chisel is held in the hand at a horizontal angle of about 55° with the central line of the file, as in the upper row of cuts at *C*, and with a vertical inclination of about 12° to 14° from the perpendicular, as represented at *A*." (Fig. 1965.)

"The blow of the hammer upon the chisel causes the latter to indent and slightly to drive forward the steel, thereby throwing up a trifling ridge or bur; the chisel is immediately replaced on the blank and slid from the operator, until it encounters the ridge previously thrown up, which arrests the chisel or prevents it from slipping farther back, and thereby determines the succeeding position of the chisel. The heavier the blow, the greater the ridge, and the greater the distance from the preceding cut at which the chisel is arrested. The chisel, having been placed in its second position, is again struck with the hammer, which is made to give the blows as nearly as possible of uniform strength; and the process is repeated with considerable rapidity and regularity, sixty to eighty cuts being made in one minute, until the entire length of the file has been cut with inclined, parallel, and equidistant ridges, which are collectively denominated the first course. So far as this one face is concerned, the file, if intended to be single cut, would be then ready for hardening. Most files, however, are double cut; that is, they have two series or courses of chisel cuts. In cutting the second course, the chisel is inclined vertically as before, at about 12°, but its edge only a few degrees from the transverse line of the file, or about 5° to 10° from the rectangle. The blows are now given a little less strongly, so as barely to penetrate to the bottom of the first cuts, and from the blows being lighter they throw up smaller burs, consequently the second course of cuts is somewhat finer than the first. The two series, or courses, fill the surface of the file with teeth, which are inclined towards the point of the file." See Holtzapffel's *Turning and Mechanical Manipulation*, London, 1847.

File-blank. A piece of soft steel, shaped and ground ready for cutting, to form a file.

File-car'ri-er. A tool-holder like the stock of a frame-saw, and used to mount a file in a manner similar to that of the saw in the case cited.

Fig. 1966.



File-Carrier.

File-chis'el. The cold chisel (*A*, Fig. 1965) for rough files is about 3 inches long, 2¼ wide, and the angle of the edge is about 50°. (See FILE.) The edge is straight. The file-blank rests upon a block of lead which forms the anvil. The narrower chisel, for cutting smaller and smoother files, has a length of about 2 inches, width ¼ inch. It is very thin and sharpened to an angle of about 35°. It is used with a hammer weighing one or two ounces. Other chisels are of intermediate proportions. The edge is always wider than the file to be cut.

The chisel is held in the left hand at an inclination of 4° to 15° from the perpendicular, according to the character of the file.

The blow of the hammer drives forward the chisel, raising a bur, the hight of which determines the distance of the next cut, as the sliding of the chisel against the ridge previously thrown up affords a gage for the position of the chisel at the next blow, the operator being guided by the sense of touch. The cuts are made at the rate of 60 to 80 per minute. The file-blank is greased before cutting.

File-clean'er. A scratch-brush of wire. A thin brass edge which acts as a rake. A card such as is used in carding cotton.

To remove wood, dip the file in hot water to swell the wood. It is then removed by a hard brush; the warmth evaporates the moisture.

File-cut'ting Ma-chine'. A machine by which files are cut automatically. The usual form has a table to which the blank is secured, and on which it is fed beneath the chisel, which receives the blows of a trip-hammer above.

Many attempts have been made in this direction in France, England, and the United States. Among these may be mentioned Duverger, 1699; Fardouet, 1725; Thiout, 1740; Brachal and Gamain, 1756, 1778; Raoul, 1800; Ericsson, 1836; Robison, 1843. See also Skilton's machine, "Ure's Dictionary," Vol. II. pp. 202–204, edition of 1860. See also "Transactions of the American Philosophical Society," Vol. II., in which a machine is described in which the file is fixed on a bed of lead, and a chisel fixed at the end of a lever is struck down by a hammer. The lever is again raised by means of a spring, and during its rise moves a ratchet-wheel connected with the support of the bed, which is shifted, together with the file, after each stroke. In Thiout's machine ("Traité de l'Horologie," Paris, 1740), the file is attached to a screw-slide suspended at the end by pivots and covered with an anvil-plate of tin. The slide works upon a stationary anvil, and is worked by a feed-screw moved at intervals the distance of the pitch of a tooth by means of a pin-wheel. The chisel is held on a jointed arm beneath which is a spring to raise it after each blow, the latter being given by a vibrating drop-hammer. Ericsson's machine was adapted to cut several files at a time, and is especially commended for the introduction of means by which, in cutting taper files, the hammer is less raised in cutting the ends of the files than at the middle, so as to proportion the force of the blow to the width and depth of the cut at different parts of the file. Two machines were used for double-cut files, the bed of one inclined to the right and the other to the left, to give

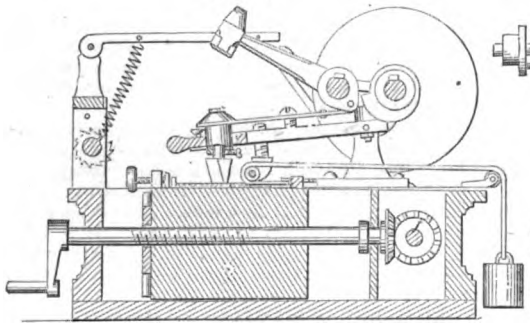
Digitized by Google

the different horizontal inclinations proper to these teeth, and a machine with a straight bed was used for single-cut *floats*, and for round and half-round files. The machines make about 240 strokes per minute, which is about three times the rate of hand-work, and two beds are employed, so that one may be cutting while the blanks are being adjusted upon the other.

Sir John Robison, formerly president of the Royal Scottish Society of Arts, suggested, in 1843, the making of curvilinear files by cutting flat strips of steel plate and then rolling them into shape and tempering them. Cammel's improvement was to make the plate thinner towards the edges, so that it might bend equally, and not too much in the middle, as it was apt to do when of an even thickness. He also suggested to make the teeth by a graver, in an automatic machine.

Fig. 1967 shows a file-cutting machine in which

Fig. 1967.

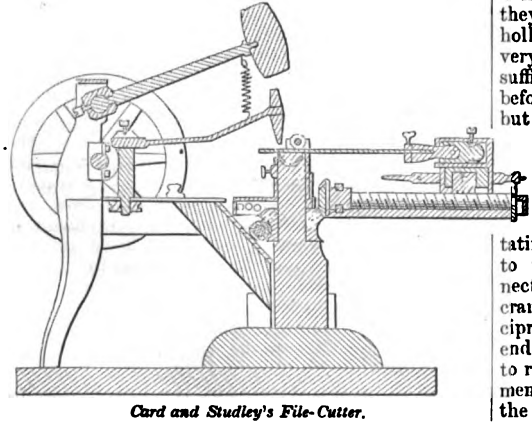


Rotherham and Holden's File-Cutting Machine.

the blanks are secured side by side on the upper surface of the bed, which is automatically fed after each stroke by the feed-screw; a separate chisel and hammer act upon each blank; the chisels are supported by springs on arms with roller feet, which bear upon the blank; the chisels are thrown back after each cut to raise a burr.

In Fig. 1968, the sliding head to which the shank of the blank is clamped is actuated by a feed-screw and half nut, the latter being automatically raised to stop the feed-motion at the proper time. The anvil has a hemispherical block, whose convex side rests in a socket of its support. The anvil and feed-

Fig. 1968.



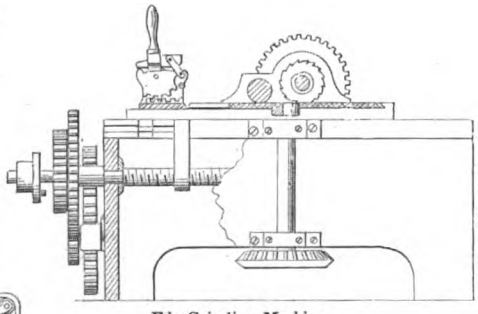
Card and Studley's File-Cutter.

movement are supported on a turn-table, by whose adjustment the inclination of the teeth is determined. The chisel is supported upon a flexible rod which is connected to the hammer-handle by a spiral spring. The hammer is attached to a rock-shaft, which has an adjustable arm acted on by a cam on the main shaft.

File-grind'ing Ma-chine'. A machine for surfacing forged or rolled file-blanks to bring them to form previous to cutting.

In the example the files are secured one after another upon a carriage which moves under a revolving cutter on a curved bed in such a manner that

Fig. 1969.



File-Grinding Machine.

the shape of each file depends entirely upon the curvature of the bed; and as long as this curvature remains unchanged, all the files turned out upon it are uniform in shape. The files are held in position upon the carriage by a sliding clamp operated by a toothed segment. This segment connects with a hand-lever in such manner that when the clamp has been made to catch over the end of the file, the toothed segment is locked and the clamp thus prevented from spontaneously releasing the file.

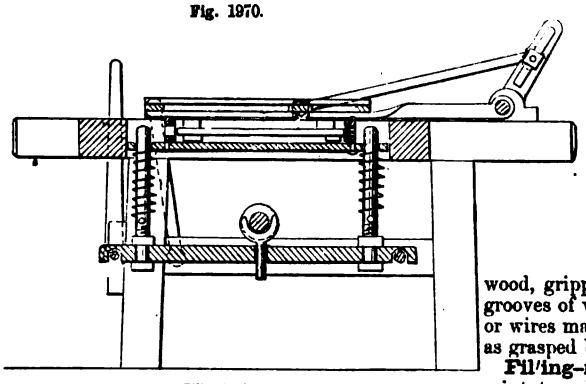
Fil'er. An office device for holding bills and loose papers. See PAPER-FILE.

File-sharp'en-ing. Worn files are first cleaned by hot water and soda; then placed in connection with the positive pole of a battery, in a bath composed of forty parts of sulphuric acid, eighty parts of nitric acid, and a thousand parts of water. The negative pole is formed of a copper spiral surrounding the files, but not touching them; the coil terminates in a wire which rises towards the surface. When the files have been ten minutes in the bath they are taken out, washed, and dried, when the hollows will be found to have been attacked in a very sensible manner; but should the effect not be sufficient, they are replaced for the same period as before. Two operations are sometimes necessary, but rarely.

File-strip'per. A machine in which a worn-out file, after being softened by heat and slow cooling, is smoothed to prepare it for being re-cut. In the example, the file is held by adjustable jaws upon a slightly rotating bed supported by springs. The cross-bar, to which the stripping-tool is attached, is connected at each end by a connecting rod with a crank upon the end of the driving shaft, and is reciprocated in guides upon a frame hinged at one end to the driving-shaft, and which may be elevated to raise the stripper off the file through the instrumentality of a rock-shaft and a system of levers at the other end.

Digitized by Google

Fig. 1970.



File-Stripper.

File-tem'per-ing. The files are drawn through beer-grounds, yeast, or other adhesive fluid, and then through common salt mixed with roasted and pounded cow's hoof, the objects of which are to protect the teeth from the direct action of the fire and the oxidizing influence of the air; to afford an index of temperature, the fusion of the salt showing when the hardening heat is attained; and to lessen the tendency of the files to crack on being immersed in water. The file is held by the tang with a pair of tongs, and immersed quickly or slowly, vertically or obliquely, according to its form; that method being adopted which has been found by experience best calculated to keep the file straight. After the hardening, the tang is tempered by immersing it in molten lead; if the tang were left as the file, it would be liable to snap off during use.

The files are next scoured with scrubbing-brushes dipped into sand and water or coke-dust and water; they are next put into lime-water and left for some hours. They are then thoroughly dried at the fire, and lastly rubbed over with olive-oil containing a little turpentine.

Fil'i-gree. Delicate jewelry-work of gold or silver wire drawn flat or round. The wire is twisted by pinchers into beautiful forms, and soldered at the junctions.

The word is Italian. The original form seems to have been a wire with grains or beads, and the term now includes plaited, interlacing, or granular work in gold or silver wire worked into ornamental forms. The nations bordering on the Mediterranean excel in the art.

The filigree of India comprises various personal ornaments of gold and silver, groups of flowers, and small boxes and caskets. Their apparatus consists merely of a few small crucibles, a piece of bamboo for a blowpipe, small hammers for flattening the wire, and sets of forceps for interweaving it.

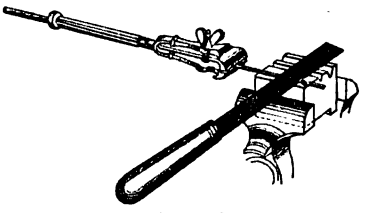
Fil'i-gree-glass. (*Glass.*) One of the kinds of ornamental glass for which Venice was formerly celebrated, and which has been recently revived.

Small filigree canes of white and other colored enamels are drawn; *whetted* off the required lengths, arranged in clusters in a cylindrical mold of the required shape, and then fused together by heat. The canes are then aggregated by flint glass at a welding heat, and the mass twisted if a spiral ornament be desired. Vases or other objects are made of ornamental masses of this glass, blown in the usual manner.

The *Venetian ball*, familiar in paper-weights, is made of waste pieces of filigree in a pocket of flint-glass.

Fil'ing-block. A block of apple, pear, or box-wood, gripped in the jaws of a vise, and having grooves of varying depth in which small rods, bars, or wires may be laid to be filed. The wire is shown as grasped by a hand-vise.

Fig. 1971.



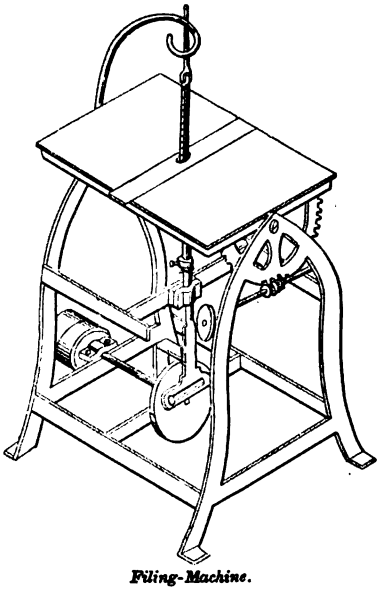
Filing-Block.

Fil'ing-ma-chine'. 1. A machine used in the mint to reduce the weight of coin planchets, when above the standard. The pieces are laid parallel in a trough, and their edges rest upon a cylindrical file, whereby a portion of metal is removed, the pieces rotating as the work proceeds, in order to preserve their circularity.

2. A machine in which a file is mounted as a jig-saw; or to reciprocate in a manner similar to that of a file in the hands of a workman.

In the example, the file receives vertical reciprocation from a pitman whose cross-head has a horizontal slot traversed by a crank-pin on a rotating

Fig. 1972.



Filing-Machine.

disk. The table is pivoted and has a semicircular rack which is engaged by a screw-gear to incline the table. See also SAW-FILING MACHINE.

Fil'ings-sep'a-ra'tor. A machine in which filings of iron and copper are separated by exposure to magnets which are brought into contact with all of the particles, and select, retain, and remove the iron particles from those of brass and copper, so that the latter may be used for re-melting. There are several forms of machines for the purpose.

Fil'let. 1. A strip of card-clothing. A strip of leather furnished with the bent wire teeth peculiar to carding-engines.

Digitized by Google

2. A ring on the muzzle or cascabel of a gun.

3. A ribbon of metal of gaged proportions fed to the machine which punches out the planchets for coining.

4. (*Carpentry.*) *a.* A square molding, frequently forming an upper finish or *corona*. A *band* or *listel*.

b. A strip nailed to a wall or partition to support a shelf.

c. A stop for room or closet doors to close against.

d. A strip inserted into the angle formed by two boards or surfaces.

5. (*Dairy.*) A perforated curb to confine the curds in making cheese.

6. (*Bookbinding.*) A rolling tool which has a plain line, lines, or band; differing in this respect from the ornamental rolls.

7. (*Architecture.*) The projection between the flutes of a column.

8. (*Printing.*) A rule with broad or broad and narrow lines, principally used as a border.

9. (*Gilding.*) A band of gold-leaf on a picture-frame or elsewhere.

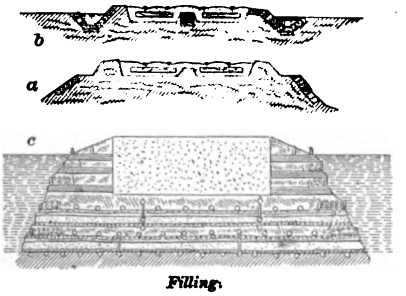
10. The thread of a screw.

Fil'let-plane. A molding-plane for dressing a fillet or square bead.

Fill'ing. 1. (*Railrouding.*) An embankment of stone, gravel, earth, etc., to make a raised bed for a road, railroad track (*a*), or canal. An artificial, elevated way.

In the laying out of a permanent way, it is usual to make the *cuttings* and *fillings* counterbalance each

Fig 1973.



Fillings.

other, as near as may be, but in a flat country the *way* is made by throwing the sides to the middle, making a bank bounded by two ditches (*b*). The customary soil in such situations, however, is unfit for the repose of the ties, and it becomes necessary to carry sound ballast, such as broken stone or good gravel, before the *permanent* way can be said to be in good order. Such is especially the case in ground naturally swampy. In such cases the track is either supported by piles, or, as in the annexed illustration (*c*), which represents a railroad embankment in Holland, by fascines and stakes, bound together and placed alternately across and longitudinally.

Among the largest embankments of modern times are the Tring filling of the Northwestern Railway, England, containing 1,500,000 cubic yards; the Gadelbach, on the Ulm and Augsburg Railroad, 1,750,000 yards; the Oberhäuser, on the Augsburg and Lindau Railway, 2,500,000 cubic yards.

Chat-Moss, on the Liverpool and Manchester Railway, is 4½ miles across and from 20 to 40 feet deep. Cattle could not stand upon it. To form an embankment of 277,000 yards, 670,000 yards of material were thrown into the bog.

2. (*Shipbuilding.*) Pieces or composition fitted in between the frames of the hold, to increase the water-tightness, resist compression, and prevent the collection of dirt, bilge-water, and vermin. Blocks of wood, bricks, mortar, cement, asphalte, have been used.

3. (*Nautical.*) A slip of wood forming a part of a built structure, such as a made mast; or a piece inserted to fill a defect.

The covering of a pile, below water, with broad-headed nails, to exclude the *Teredo navalis*.

4. (*Weaving.*) The *weft*-thread which fills up the *warp*, being introduced by the shuttle and beaten up by the *batten* or *lathe*. Also known as the *woof*, *shoot*, or *train*.

5. A stopping for carious teeth. The filling of decayed teeth with gold was practiced by the Egyptians, as is proved by some mummies found at Thebes. See DENTAL INSTRUMENTS AND APPLIANCES.

Fill'ing-en'gine. (*Silk-machinery.*) A machine in which waste and floss silk from the regular silk-machinery is disentangled, and the fibers laid parallel. The silk, previously hackled, is fed between rollers and subjected to the action of a series of moving combs. It then passes to the *drawing-frame*, where it is subjected to a farther process of substantially similar character. From the *drawing-frame* it passes to the *scutcher*, and thence to the *cutting-engine*, which cuts it into lengths of about 1¼ inches. The staple is then cleansed, dried, and eventually *carded* and *doubled*, *drawn* and *spun*, like cotton.

Fill'ing-in Pie'ces. (*Carpentry.*) Timbers occurring in partitions, groins, and roofs of less length than those with which they range; as the jack-rafters next a hip, and the short rafters filled in the side of a roof next the chimney-shaft.

Fill'ing-pile. (*Hydraulic Engineering.*) A backing or retaining pile in a coffer-dam.

Fill'ing-post. (*Architecture.*) A middle post in a wooden frame.

Fill'ing-tim'bers. (*Shipbuilding.*) Those placed between the frames to fill up.

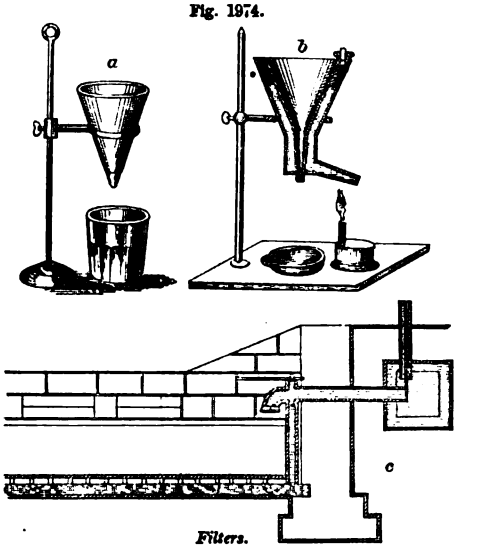
Fil'lis-ter. 1. The rabbet on the outer edge of a sash-bar, to hold the glass and the putty.

2. A plane for making a rabbet. The varieties are known as *side*-fillisters and *sash*-fillisters.

The former is regulated for depth by a movable stop. See PLANE.

Fil'ter. A vessel, chamber, or reservoir through

Fig. 1974.



Filters.

Digitized by Google

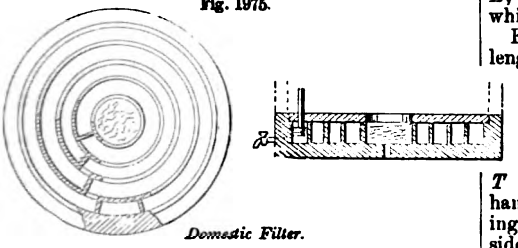
which water or other liquid is passed to arrest matters mechanically suspended therein. The idea does not necessarily include specific chemical action, though doubtless animal and vegetable charcoal have a faculty for absorbing gases and deleterious and effete matter, especially organic.

The filter (*a*, Fig. 1974) of the laboratory is made of a circle of bibulous paper, folded and opened into a quadrant and inserted into a funnel of glass or porcelain, and the filtering material is a quadrant of bibulous paper which is rolled into a cone and fitted into the funnel. Crushed and powdered glass, and gun-cotton are also used.

The filter *b* (Fig. 1974) is placed within a water bath which has a leg heated by an alcohol lamp. This is used for filtering matters which become viscid by cooling, such as gelatine, tallow, wax, stearic acid, etc. All filters for the laboratory, in which a sheet of paper is made to line a funnel and contain the liquid, should have sides subtending an angle of 60°; this for the reason that a sheet of paper folded in four, and one corner opened so as to form a cone, fills a funnel of the shape described.

The domestic filter frequently consists of a submerged jar or box made of a natural or artificial po-

Fig. 1975.

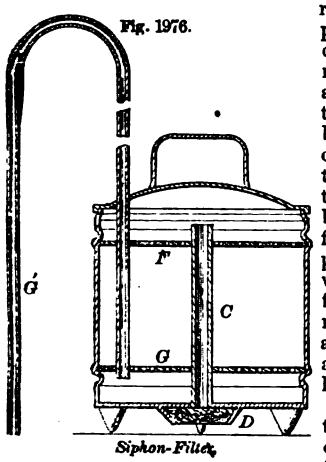


Domestic Filter.

rous stone, through which water passes, and which is withdrawn by a faucet which crosses the intervening space and passes to the outside. In another form it is a chamber at the bottom of the water-reservoir, as in Fig. 1975. The water passes down into the sponge-pocket, and thence follows around the circuitous chamber charged with filtering material to the outlet.

In another form, the filter is placed within a barrel, and the water passes through a coarse filter *D* beneath it, and up a central tube *C* to an upper chamber, and from this chamber through the filtering material contained between two perforated diaphragms *F G*. The water is drawn from the lower annular chamber by a siphon *G'* having a stop-cock at its lower end.

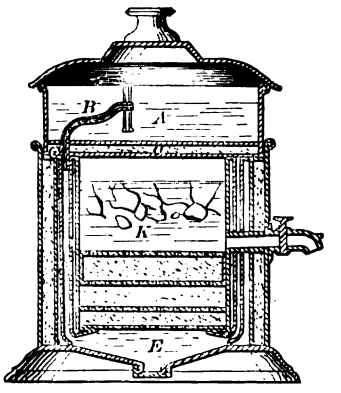
Fig. 1976.



Siphon-Filter.

A good domestic form consists of a deep wooden tub divided by a tight vertical partition through the middle, the partition at the bottom being perforated with numerous small holes. The tub is nearly filled on both sides of the partition with granulated charcoal made from sugar-maple, and screened through a mesh of one sixteenth of an inch, the fine dust being separated by bolting. The foul water enters the tub on one side at the top, passes downward and through the small holes in the partition, and rises upward on the other side, leaving its impurities, both solid and gaseous, in the charcoal.

Fig. 1977.

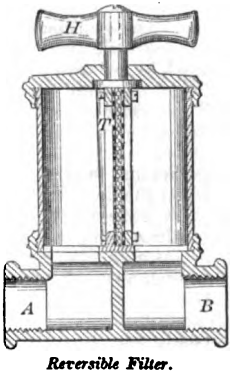


Filter and Cooler.

Fig. 1977 shows a filter and cooler combined. The water from the reservoir *A* above passes into a tube *B*, whose mouth is vertically adjustable, and is introduced below the filter-bed *E*, through which it passes upward into the ice-chamber *K*.

Fig. 1978 is a reversible filter interposed in a length of pipe. The water flowing from *A* to the filtering-surface *T* has its impurities detained, while the strained water runs off at *B*, and pursues its course along the pipe. When the filter-surface *T* has become foul, the handle *H* is turned, throwing the dirt to the delivery side, by which it is carried off, the water being allowed to run to waste until the surface is cleansed and the water runs clear.

Fig 1978.



Reversible Filter.

The filter for rain-water is a part of, or is placed at, the end of the spouting or conductor for the rain-water.

It is usually a box or chamber containing charcoal or sand, which prevents leaves, decayed wood, or other foreign matter, from passing to the cistern. It has a detachable section which intervenes between the conductor and the filter, and has a perforated strainer which arrests leaves and other larger matters which can be removed from time to time by separating the sleeve-joint coupling.

Asbestus has been used for filtering, and has this merit among others, that it may be purified readily by making it red hot.

M. Maurras's filter is a water-tight iron box 5½ feet square, with a filtering surface of 60 superficial feet, which, with a head of 12½ feet, is calculated to filter 150,000 gallons of water per diem. It percolates from the circumference inward, passing through fine and coarse sand, is received in a central chamber from whence it is discharged by a pipe. The chamber contains a number of perforated boxes containing sand which cannot pass the interstices; between these are layers of fine and coarse sand. The reversal of the current agitates the contents so as to stir up the sediment, which passes off to the waste-pipe, till the sand is cleaned. The ordinary flow is then resumed.

Digitized by Google

The mode of filtration in those of the London Water-Works, wherein this process of purification is used, is by the descent of the water, which passes through strata of fine and coarse river sand, broken shells, and pebbles, small and large gravel. These are placed in the bottom of the reservoir, so as to present an undulated surface. Below these are tunnels made of brick, built open-jointed. The sediment penetrates to a depth of from 6 to 9 inches, and that much of the surface-sand is frequently removed, portions of the area at a time. An acre of area filters 300,000 to 400,000 cubic feet daily.

A natural filter is used at Nottingham, England, the reservoir being dug in such position as to receive its water by percolation from the river through a bed of fine sand, which intervenes between the two. The sedimentary matter is continually washed away from the river face of the filter by the action of the stream.

The filter of Greenock, Scotland, is a tank 50 feet long, 12 wide, and 8 deep. The water percolates either upward or downward through the filtering material as it may be directed. After the filter has become foul, by opening a sluice the water is turned in the other direction, passing upward through the filter, and passing off by a waste-sluice. After the water is cleansed, the sluices are changed and the filter operates as before. There are three of these filters in the works.

The filter of Paisley (*c*, Fig. 1974), constructed by Thom, is upon the principle just stated. Water is admitted to the filter by opening a sluice, and runs upon the surface of the filtering material through which it percolates, and passes off by the main. The stop-cock is kept closed so long as the filter does effective duty, but when it becomes choked by sedimentary matter and mud, the stop-valve of the main is closed, the stop-cock lowered, and the water carried by a pipe *beneath* the filtering material, so that the upward pressure will dislodge the mud and carry it up through the various strata of gravel and sand.

Upon the floor of the filter bricks are laid edgeways, a little apart from each other at all points; upon these perforated tiles are laid, nearly touching. The strata of filtering material are successively, —

Gravel, about $\frac{3}{10}$ inch in diameter.

Gravel and sand, four courses of gradually increasing fineness.

Sand, fine, clean, and sharp, 2 feet deep. The upper 6 or 8 inches mixed with broken animal charcoal; say pieces $\frac{1}{16}$ inch in diameter.

When cleaning the filter bed by the upward pressure of water, the upper part of the stratum of sand is raked to dislodge the mud, which is apt to accumulate at the surface.

The filter-bed is 60 × 100 feet in area, divided into three compartments capable of separate use. It is made in a level piece of ground excavated to the depth of 6 to 8 feet, and lined on sides and bottom with a wall puddled in the rear, and laid in hydraulic cement.

The water filtered amounts to 106,632 cubic feet in twenty-four hours.

Natural filters consisting of beds of gravel or sand intervening between a pumping well and a muddy river or sea water, as the case may be, are found in many places; Dayton, Ohio, and Cape Cod may be mentioned, in addition to that at Nottingham, England, just cited.

The filter for sirups is charged with bone-black, revived from time to time by reburning to consume the absorbed organic matter. As a mere filter, cloth covered with paper pulp has been used successfully for sirups. See SUGAR-FILTER; CENTRIFUGAL-MACHINE.

The filter for separating the mucilaginous matters from vinegar is charged with wood-shavings, straw, spent tan-bark or *rapes*. The latter consists of stalks and skins of grapes from which the must has been expressed. *Rapes* are far preferable to any other material. The vinegar is passed again and again through the filter.

Air-filters are used for arresting dust, steel-filings, smoke, etc., according to circumstances and exposure. (See AIR-FILTER.) A filter recommended by Professor Tyndall consists of a cylinder four or five inches long and two inches or more in diameter. Its interior contains, at the top, a layer of cotton-wool which has been moistened with glycerine, then a layer of dry cotton-wool, then a layer of charcoal, then cotton-wool, with wire-gauze covers at both ends, and at the upper end a mouth-piece so shaped as to fit closely over the mouth of the wearer. By drawing the breath through this instrument, the most dense smoke may be entered with impunity. When places are to be entered, such as mines or wells, where carbonic-acid gas is present, it is necessary to add another layer of cotton-wool, and to place between the two bottom layers of cotton a layer of slaked lime to arrest moisture and carbonic-acid gas. See also INHALER; RESPIRATOR.

Fil'ter-bed. A settling pond whose bottom is a filter. It may consist of a reservoir 5 feet deep with a paved bottom covered with open-jointed tubular drains leading into a central conduit. The drains are covered with a layer of gravel and a top layer of sand. The water is delivered upon the surface uniformly, and the rate of subsidence is about six inches an hour. The more rapid the rate (other things being equal) the less effective is the operation. See FILTER.

Fil'ter-fau'cet. One having a chamber containing sand, sponge, or other material to arrest impurities in water.

Fil'ter-ing Ba'sin or Tank. (*Hydraulic Engineering.*) The chamber in which the water from the reservoir of water-works is received and filtered previous to entering the mains. See FILTER.

Fil'ter-ing-hy'drant. One which subjects the water from the service-pipe and main to the action of a material to arrest mud.

Fil'ter-ing-pa'per. A bibulous, unsized paper, thick and woolly in texture, used for filtering solutions in the pharmacy or laboratory. Swedish filtering-paper is thinner and of superior quality.

Fil'ter-ing-press. One in which the passage of a liquid through a body of filtering material is expedited by pressure applied thereto. A *pressure-filter*.

Fin. 1. A mark or ridge left in casting at the junction of the parts of the mold.

2. A slip inserted longitudinally into a shaft or arbor, and left projecting so as to form a guide for

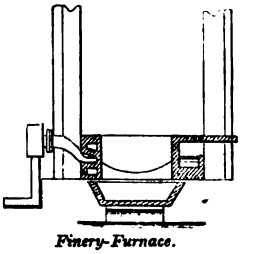
Fine-draw'ing. A finishing process with cloth in which it is subject to a strong light while all faulty parts or breaks in the fabric are closed by sound yarn introduced by a needle.

Fine-nail. A name used in some trades to distinguish a relatively thin from a coarse nail, such as a fencing nail or clout. A *finishing* nail.

Fine'ness. The quantity of pure metal in an alloy expressed in 1,000 parts; as the fineness of United States coin is 900, the other 100 being alloy.

Fin'er-y-fur'nace. A species of forge-hearth in which gray cast-iron is smelted by fuel and blast, and from which it is run into iron troughs for sudden congelation. The result is a finer quality of cast-iron of whiter color, which is subsequently puddled and made malleable. The furnace is of brick with hollow iron lining, through which water circulates. The fuel is coke or charcoal, and the melted metal is run from the crucible into a pit, where it is quenched with water to render it brittle, and perhaps oxidize it somewhat.

Fig. 1979.



Finery-Furnace.

Fine-stuff. Lump lime slaked to a paste with a moderate volume of water, and afterward diluted to the consistency of cream, and then left to harden by evaporation to the required consistency for working over a floating-coat of coarse-stuff.

In this state it is used for a *slipped-coat*, and when mixed with sand or plaster-of-paris it is used for the *finishing-coat*.

Fin'ger. 1. (*Machinery.*) *a.* A small projecting rod or wire, which is brought into contact with an object to effect or restrain a motion. The derivation of the name from the human finger is apparent, and the action is sometimes marvelously similar; as in the delicate pieces of tactile and prehensile mechanism in the stop-motions of machines working in fiber. Known as a gripper in printing-machinery.

b. One of a row of similar projections, as the finger of a rake. Sometimes, as in the example, synonymous with *tooth*.

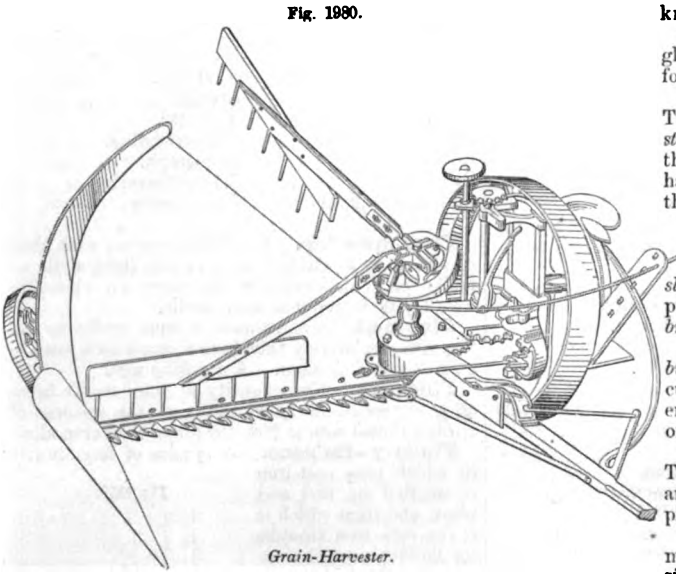
2. (*Husbandry.*) One of the projecting pieces on a finger-bar of a harvester, within and against which the knives play. See FINGER-BAR.

Fin'ger-bar. (*Agriculture.*) The bar of a reaping or mowing machine, whose front edge has pro-

Digitized by Google

jecting fingers, called *guards*, through whose horizontal slots the serrated knife reciprocates. (See GUARD.) Moving in either direction, the knife sections make a shear cut against the sharp edges of the guards, so as to sever the stalks of grain or grass which are divided either way by the guards, which hold the stalks laterally as the knives make their draw-cuts against the stems. The illustration shows the finger-bar in its relation to the quandrantal

Fig. 1980.



Grain-Harvester.

platform, revolving-rakes and driving and supporting mechanism.

Fin'ger-board. The neck of a stringed instrument of the viol, banjo, or guitar class, on which the strings are pressed by the fingers in playing.

Fin'ger-grip. (*Well-boring.*) A tool for recovering rods or tools dropped into a bored shaft. It consists of a rod having a foot which is twisted around so as to penetrate beneath the object and enable it to be lifted and withdrawn. See GRAB.

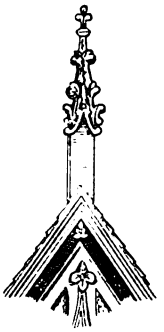
Fin'ger-nut. A nut with wings to afford a hold.

Fin'ger-plate. A plate on the side of a door, near the edge, to keep finger-marks from the paint.

Fing'roms. (*Fabric.*) Cloth made of *combed* wool.

Fin'i-al. A pointed ornament or pinnacle surmounting the apex of a Gothic gable.

Fig. 1981.



Finial.

Specifically, a bunch of foliage which terminates pinnacles, canopies, pediments, etc., in Gothic architecture.

Fin'ing. 1. Material used to add to a turbid liquid to clear it. As the isinglass or albumen subsides in the liquor, it carries down the particles mechanically suspended therein. In this way, wine, cider, sirups, and many solutions are cleared.

2. (*Metallurgy.*) Treatment of metal to remove impurities and foreign matters, as the fining (refining) of cast-iron to convert it to malleable iron by the removal of the carbon, etc.

Fin'ing-forge. (*Metallurgy.*) An open hearth with a blast by which iron is freed of impurities or foreign matters. Cast-iron is thus rendered malleable. See Fig. 1979.

Fin'ing-pot. (*Metallurgy.*) A crucible in which metals are refined.

Fin'ing-roll'er. (*Paper-making.*) A cylindrical wire-cloth sieve in the paper-making machine, which allows the finely ground stuff to pass, but restrains the coarse fibers and knots.

Fin'ings. A solution of isinglass, gelatine, or white of egg, for clarifying liquids.

Fin'ish-er. 1. (*Paper-making.*) The second *beating-engine*, or *half-stuff engine*, which operates upon the partially worked rags that have been previously reduced in the *stuff-engine* and then bleached.

2. The final carding-machine, which perfects the *fleece* or delivers the *sliver*; as distinguished from the prior machine, known as the *breaker*. A *finishing-card*.

Fin'ish-er's Press. (*Bookbinding.*) A small press, like a cutting-press, used by the finisher, who does the ornamental work on the cover.

Fin'ish-ing. 1. (*Engraving.*) The work of the graver, dry-point, and machine-ruler upon an etched plate.

2. (*Bookbinding.*) The ornamental work on a book after it is simply covered with leather or cloth, which is known as *forwarding*.

The term has many applications in the useful and ornamental arts, when a second set of workmen take up and *finish* a work which is systematically passed through a series of hands in regular order of time.

Fin'ish-ing-card. A machine in which the process of carding is repeated. The machine which first operates upon the material is known as the *breaker*-card. See CARDING-MACHINE.

Fin'ish-ing-coat. (*Plastering.*) The third coat on the better style of work. For painting, it consists of the best stuff, and is called *stucco*. For paper, it consists of the same as the previous coat, and is called *setting*.

Fin'ish-ing-ham'mer. The last hammer used by the gold-beater. The series is as follows: —

The *flat* or *enlarging hammer*; the *commencing*-hammer; the *spreading*-hammer; the *finishing*-hammer.

The latter has a more convex face than either of its predecessors; it has a face 4 inches diameter, and weighs 13 or 14 pounds. See GOLD-BEATING.

Fin'ish-ing-rolls. A second set of rolls in a rolling-mill. The first set is the *roughing-rolls*, which operate on the bloom from the tilt-hammer or squeezer and reduce it to *bar* form. This is then cut up, piled, reheated, and taken to the finishing-rolls, which make it into bar or rod iron. The reheating purifies, and the second rolling improves the tenacity by the repetition of the drawing. The finishing-rolls run at a speed two or three times greater than the roughing-rolls, according to size.

Fire-a-larm'. An automatic arrangement by which notice of fire is given. It depends for its action upon the increased temperature of the air in the vicinity of the fire, or upon the burning away

Digitized by Google

of certain connecting cords which are stretched in exposed situations.

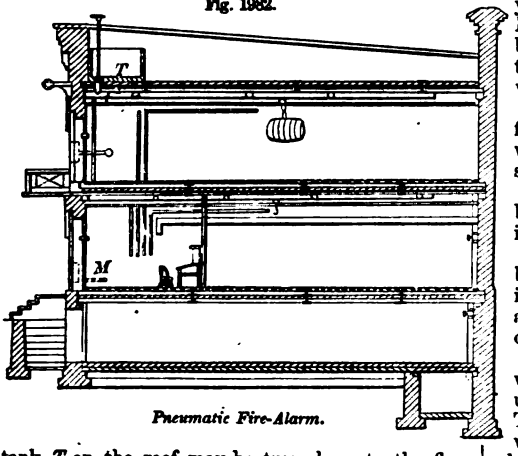
Some of these alarms are designed to give audible notice in a central situation, say at a police or fire-alarm telegraph station, the office of a warehouse or store, the bedroom of a dwelling, the cabin of a vessel. Others, in addition to the said notice, turn on a body of water to the floor whence the notice has come, or break a bottle of acid to liberate carbonic-acid gas in a reservoir of chemicals previously prepared.

a. That form of fire-alarm which depended upon the burning away of hempen springs to give the alarm, was patented in England by Joseph Smith, 1802. Cords are stretched through various rooms in the house, and connect with an alarm apparatus in the office or the bedroom of the person in charge. The cords are saturated with inflammable material, which assists in their combustion when the fire reaches them, and the breaking of either causes its alarm-weight to fall.

b. Another kind of fire-alarm has tubes throughout the building. The tubes proceed from each floor and apartment to a central office, and the occurrence of fire in either causes an expansion of air which is evidenced by a blast of air from the tube.

In the example, a farther arrangement is made, by which from the office *M* a stream of water from a

Fig. 1982.



Pneumatic Fire-Alarm.

tank *T* on the roof may be turned on to the floor when the alarm has been transmitted.

c. The increased heat of the apartment causes expansion of a body of mercury, and brings it in contact with a wire of a metal which readily amalgamates. The wire then breaks with the strain applied to it. The fracture of the wire releases the escapement of the clock-work, and the hammer strikes the alarm-bell. The same automatic agency turns a cock and admits an extinguishing agent which is kept in reserve.

d. A thermostatic arrangement by which a closure of an electric circuit is made when the metal expands under the increment of heat. The thermostat is a column of mercury, which ascends in a tube and makes the electric connection; or a plate or coil of two metals on the principle of the chronometer-balance, or it is an elongating rod.

The connection made, an armature in the telegraphic-wire circuit is attracted by its magnet and releases a clock-work alarm.

The Tunnicliffe fire-alarm has a cylindrical barrel 3 inches long by 1½ inches in diameter, which, by a screw attached midway along its length, may be readily secured to the ceiling or any part of the room desired. It contains, when ready for use, a small charge of powder, to which is attached an inch of fuse. This fuse is formed of a chemical mixture that will ignite whenever the surrounding atmosphere is heated to 200° F. In case of fire, the heat which ascends to the ceiling quickly ignites the fuse and causes an explosion sufficiently loud to be heard all over an ordinary four-story building. The alarms can be so arranged as to ring bells in any desired room in the building where placed, and may be attached to wires connected with burglar-alarms in stores and residences.

Fire-a-larm' Tel'e-graph. The name applied to the system of telegraphy usually adopted in this country for giving notice of fires.

The first practical applications of the telegraph to this purpose were in 1851 in the cities of New York and Berlin, that in the latter under charge of one of the Siemens brothers. These systems simply connected a series of watch-towers, wherein watchmen were stationed, by an ordinary Morse line, so that the watchmen could telegraph to each other the locality of a fire.

The present system is that of Farmer and Channing, American patent of May 19, 1857.

Mr. Channing first devoted his attention to this subject in 1845, and published several articles that year attempting to show its feasibility. In 1848, Mr. M. G. Farmer invented a method of ringing bells by electricity, and in an experimental trial that year the bell in the tower of Boston City Hall was rung by an operator in New York.

In 1851, Boston appropriated money to build a fire-alarm telegraph, and early in 1852 the line was completed, put in operation, and proved a success.

That system is still in use, the improvements being in the mechanical devices for carrying it into effect.

It comprised a central station, a series of signal-boxes at suitable intervals over the city connected in one or more circuits to the central station, and a series of alarm-bells connected to the central office on another circuit.

The signal-boxes contained a circuit-breaking wheel, having upon its periphery cogs or teeth, upon which a spring, pressing, closed the circuit. These cogs or teeth and their interdental spaces were so arranged on each wheel that, when the wheel was revolved by hand, the circuit was made and broken, to indicate the number given to the box making the signal. This number, being received at a central station, was immediately transmitted on the bell-circuit, bells being struck so as to indicate the box from which the alarm originated.

In the original boxes the circuit-wheel was turned by hand; in the later boxes the wheel is turned by clock-work driven by a spring. In lieu of an operator at the central station, a repeater is there used, the alarm from the box-circuit being automatically repeated thereby upon the bell-circuit. Sometimes the bells and boxes are united in one circuit, so that from a box the general alarm is directly given. These modifications constitute what is known as the "Farmer and Channing improved" or "automatic system," from the fact that no operators at all are necessary, the turning in of an alarm at any station setting in motion all the machinery of the system.

William B. Watkins, in his patents of January 31, 1871, has extended the system so that fire or the operations of burglars automatically give an alarm at a

Digitized by Google

central station. In each house (and each room, if desired) thermostats, composed of metallic strips, are so arranged as to close the circuit of a local line upon a certain elevation of temperature, expanding the strips. Such closing actuates a local magnet, whose armature releases a detent of the signal-box mechanism, allowing the signal-box in main circuit to send in the alarm. On the same local circuit are also arranged burglar-detectors, so that a door or window being opened closes the local circuit with the same result.

Fire-an-ni'hi-la'tor. Invented by Phillips in 1849. A vessel is charged with a mixture of dried ferro-cyanide of potassium, sugar, and chlorate of potassa. It is set in action by a blow on a glass bottle which contains sulphuric acid, which flows over the charge and liberates gas which is emitted at a nozzle and expended upon a fire to quench it. See FIRE-EXTINGUISHER.

Fire-arm. A weapon which projects a missile by the explosion of gunpowder. It succeeded the long and cross bows, but the periods of the two weapons in Europe lapped upon each other. (See ARROW; BOW.) The bow and arrow are yet used by millions in Asia, Africa, and America, but the owners are always glad to trade for muskets and rifles.

The first fire-arms were doubtless rockets, in which the force of the explosion carried the tube. To these probably succeeded something of the nature of the fire-works known as Roman candles, in which pellets are loaded into a tube and fired by a match at the tube-mouth. The tubes were of bamboo, paper, or cloth, probably each of these, according to circumstances. (For early notices, see GUNPOWDER.) The cracker was used as a grenade anciently in China, and in the 8th century by the Greeks.

The first fire-arms used in Europe were cannon. (See ARTILLERY; CANNON.) Fire-arms to be carried by the soldier were a later invention. The *arquebus* was used in 1480. The musket by Charles V. in 1540. These used matches or match-locks. The wheel-lock was invented 1517; the flint-lock about 1692. The percussion principle by the Rev. Mr. Forsythe, in 1807. See GUN-LOCK.

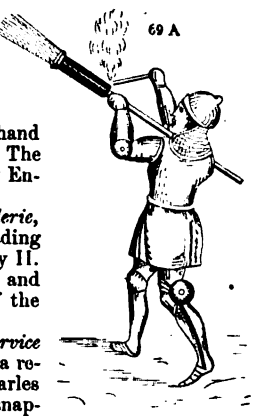
This article treats of breech-loading small-arms generally; *magazine fire-arms*, *needle-guns*, *revolvers*, *pistols*, *cannon*, and *battery-guns* are also considered under their respective heads.

"It was in 1430," says Biblius, "that small-arms were contrived by the Lucquese, when they were besieged by the Florentines." A French translation of Quintius Curtius, preserved in the British Museum, has the earliest illustration of hand fire-arms yet discovered. The cut is from the "Penny Encyclopædia."

Fig. 1983.



Fire-Arm of the Fifteenth Century.

In the *Musée d'Artillerie*, Paris, is a breech-loading arm of the time of Henry II. of France, prior to 1550, and a match-lock revolver of the same period.

In the *United Service Museum*, of London, is a revolver of the time of Charles I. It is called "a snaphaunce self-loading petronel." It has a revolving cylinder containing seven chambers with touch-holes. The action of lifting the hammer causes the cylinder to revolve, and a fresh chamber is brought into connection with the barrel. Six of the seven chambers are exposed to view, and the charges are inserted without the aid of a ramrod.

Speaking generally, the early hand-guns were breech-loaders. See REVOLVER.

Abraham Hall's English patent, 1664, had "a hole at the upper end of the breech to receive the charge, which hole is opened or stopped by a piece of iron or steel that lies along the side of the piece, and movable by a ready and easy motion."

Henry VIII. took much interest in fire-arms, and two weapons, yet extant, manufactured during his reign, were substantially the same as the modern Snider rifle.

Among the curiosities of this branch of invention is Puckle's English patent, No. 418, May 15, 1718. The accompanying illustration is from the original drawing attached to the patent, and the description following is that filed by the inventor.

"A DEFENCE.

Defending KING GEORGE, *your* COUNTRY *and* LAWES
Is defending YOURSELVES *and* PROTESTANT CAUSE.

A Portable Gun or Machine, called a Defence. For Bridges, Breaches, Lines, and Passes, Ships, Boats, Houses, and other Places.

No. 1. The barrel of the gun.
2. The sett of chambers charg'd put on ready for fireing.
3. The screw upon which every sett of chambers play off and on.
4. A sett of chambers ready charg'd to be slip'd on when the first sett are pull'd off to be re-charg'd.
5. The crane to rise fall and turn the gun round.
6. The curb to level and fix the guns.
7. The screw to rise and fall it.
8. The screw to take out the crane when the gun with the trepeid is to be folded up.
9. The trepeid whereon it plays.
10. The chain to prevent the trepeids extending too far out.
11. The hooks to fix the trepeid, and unhook when the same is folded up in order to be carried with the gun upon a man's shoulder.

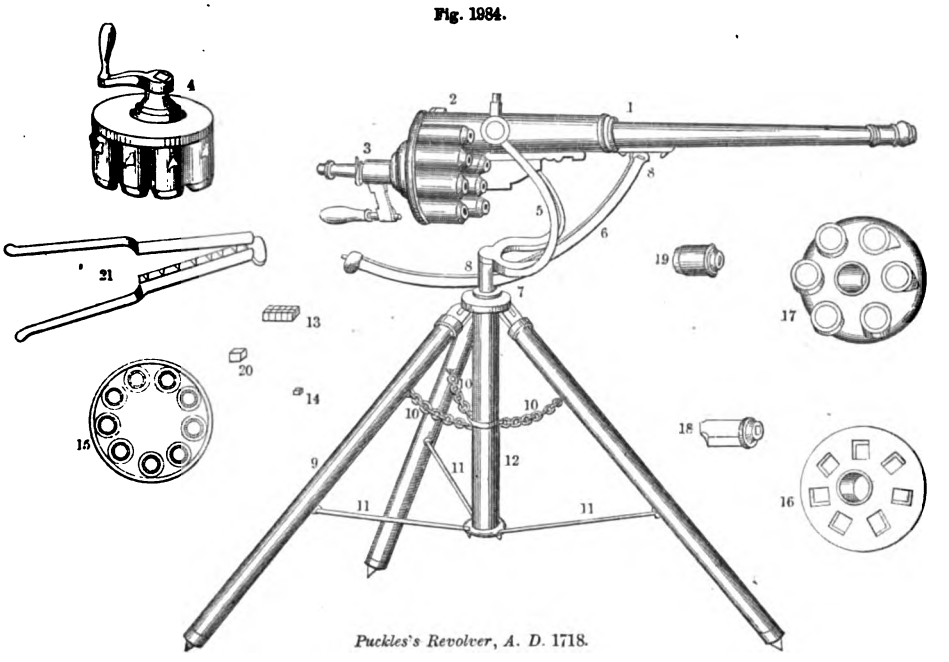
BREECH-LOADING FIRE-ARMS.

PLATE XVI. (*American and European.*) *See page* 851.

Digitized by Google

Fig. 1984.



Puckle's Revolver, A. D. 1718.

No. 12. The tube wherein the pivot of the crane turns.
13. A charge of twenty square bullets.
14. A single bullet.
15. The front of the chambers of a gun for a boat.
16. The plate of the chambers for a gun for a ship, shooting square bullets against Turks.
17. For round bullets against Christians.
18. A single square chamber.
19. A single round chamber.
20. A single bullet for a boat.
21. The mold for casting single bullets."

The parts of a gun are: —

Ante-chamber; the cavity which connects the hollow of the nipple with the chamber in the breech.

Barrel; the tube out of which the load is discharged.

Bead; the silver knob for sighting on the end of the barrel.

Bolt; the sliding piece which secures the barrel to the stock.

Breech; the piece containing the chamber which screws into the barrel.

Butt; the broad end of the stock which is placed to the shoulder.

Cap; the brass tube which incloses the worm of the ramrod.

Chamber; the cavity of the breech in which the powder is deposited and exploded.

False-breech; the iron piece on the gun-stock which receives the breech-claws, and assists in holding the barrel firmly to the stock.

Guard; the metallic scroll which defends the triggers.

Heel-plate; the plate on the butt.

Lock; the piece of many parts by which the gun is fired. See GUN-LOCK.

Loop; the clasp on the barrel through which the bolt passes and secures it to the stock.

Nipple; the tube on which the cap is placed, and through which the powder reaches the charge.

Nipple or *cone wrench;* a small turning tool for securing or loosening the nipple, to and from the barrel.

Pipes; short tubes which hold the ramrod to the barrel.

Rib (upper and under); the center-piece which unites the barrels.

Side-nail; the screw which fastens the lock to the barrel.

Sight (breech and muzzle); an object or depression on the breech, a bead or knob on the muzzle, by bringing which into line with the object the line of fire is directed.

Trigger-plate; the iron plate in which the triggers work.

Worm; the screw at the end of the ramrod.

Of the gun-lock the parts are the

Bridle.	Sear-spring.
Chain, or swivel.	Spring-cramp.
Cock, or hammer.	Trigger.
Lock-plate.	Tumbler.
Main-spring.	Tumbler-screw.
Sear.	See GUN-LOCK.

The first patent in the United States for a breech-loading fire-arm was to Thornton and Hall of North Yarmouth, Mass., May 21, 1811. Between that time and 1839 more than 10,000 of these arms were made and were issued to the troops in garrison and on the frontier. This gun is represented at *N*, Plate 16, and had a breech-block, which was hinged on an axial pin at the rear, and tipped upwardly at front to expose the front end of the charge-chamber. The flint-lock and powder-pan were attached to the vibrating breech-block. The arm is shown and described in detail in General Norton's "American Breech-Loading Small-Arms," New York, 1872.

Before the war of 1861 – 65, the principal breech-loading small-arms were Sharps's, Burnside's, Maynard's, Merrill's, and Spencer's.

Sharps's rifle (*O*, Plate 16) has the barrel rigidly attached to the stock, the rear being opened or closed by a vertically sliding breech-block, which slides up and down in a mortise operated by the trigger-guard, which is pivoted at the front end, or by a lever.

Digitized by Google

The primer consists of small pellets of fulminate inclosed in a copper casing so as to be water-proof. These are placed in a pile in a hole in the lock-plate, forced upward by a spiral spring, the upper one fed forward by a plunger, caught by the cup of the hammer, and carried down upon the nipple. The cartridge is in cloth, the end covered with tissue-paper saturated with saltpeter, through which the fulminate will ignite the powder.

Burnside's rifle (*P*) has the barrel attached to the stock, the breech-piece being pivoted beneath the barrel, so as to swing downward and expose the chamber in the front end of the breech-piece for the insertion of the cartridge.

In Maynard's rifle (*D*) the barrel is pivoted to the front end of the stock, and its rear end tips upwardly, exposing the chamber for the cartridge, when the barrel is tipped down against a solid breech-piece and locked. The Maynard primer consists of pellets of fulminate placed at regular intervals between narrow strips of paper. This is coiled in a chamber in the lock-plate, and is fed forward by a wheel operated by a hammer, so as to bring a pellet on top of the nipple at each discharge.

The Merrill gun (*E*) was constructed for a paper cartridge. The breech was closed by a sliding plug locked in place by a combination of levers. The charge was exploded by a copper cap, placed upon the nipple in the ordinary manner.

The Spencer rifle (*F*) is both a magazine and a single breech-loader, seven cartridges being placed in a magazine in the but, and being thrown forward to the chamber as required. The breech-block is a sector pivoted beneath the level of the barrel, and retreating backward and downward to expose the rear of the bore for the insertion of the cartridge. The trigger-guard forms the lever for moving the breech-block.

The Roberts gun (*L*) has a breech-block pivoted at the rear, operated by a lever which extends backwardly over the small of the stock; the forward end of the breech-block being depressed, the center of its motion and its abutment in firing being a concave solid base centering on the exact prolongation of the axis of the barrel. The breech parts are four in number, articulated without pins or screws. The firing-pin passes centrally through the breech-block, and is driven forward on the center of the cartridge by a blow of the hammer.

The Martini gun (*A*) is the invention of a Swiss. The breech-block is pivoted at its upper rear portion, being moved up and down by a lever at the rear of the trigger-guard. The firing is by a spiral spring, which actuates a firing-pin. The cartridge-shell extractor works on a pivot below and behind, the barrel being operated by the descent of the front end of the breech-block upon one arm of the bell-crank lever.

The Chassepot gun (*B*) is the French arm, and is named after its inventor. It is what we term a bolt-gun, an opening on the right hand of the chamber admitting the insertion of the cartridge. The forward thrust of a knob drives the cartridge into the breech, and a partial rotation of the knob locks the breech-piece. The firing is by a needle.

The Prussian needle-gun (*C*) is also a bolt-gun, having an inner bolt which forms the firing-pin, a sleeve around it, and an outer cylinder. The parts are shown with the needle in its fired position. In preparing to reload, the rear knob is withdrawn, and the axial bolt retained by a catch which engages a projection, withdrawing the needle. The chamber is then unlocked by the knob and slid back, the cartridge inserted and driven into the breech by the chamber, which is locked by a partial rotation. The firing is done by releasing the needle-bolt.

The Laidley gun (*G*) has a breech-block pivoted beneath the barrel and rotating backward and downward to open the chamber. When in position for firing, it is fastened by a locking-brace which is operated by a spring, and vibrates on the same axis as the hammer. The breech-block is unlocked by a cam and thrown back by a pawl attached to the locking-brace and actuated by the hammer.

The Westley-Richards gun (*H*) is an English arm having a pivoted breech-block whose front end is depressed by the action of a lever pivoted to the stock beneath the rear of the barrel.

The Snider gun (*I*), built at Enfield, England, is similar to our Springfield converted rifle, of which presently. The breech-block is hinged to the rear of and above the barrel, the block throwing upward and forward, exposing a chamber in rear of the bore. Into this the cartridge is dropped, pushed into the bore, the block brought down and locked by a latch in the rear. The firing-pin passes obliquely through the block and is struck by the ordinary hammer.

The Berdan form of this type is shown at *J*, and has a breech-block in two sections hinged together.

K is the Peabody gun, which has a falling breech-block, hinged at the rear and depressed by the guard-lever, whose short arm engages in a recess of the block and controls its movements. When the block is down, the cartridge is slipped into the bore, and the piece is fired by the fall of the hammer upon a firing-pin sliding in a groove in the side of the block. In opening to reload, the block drops upon an elbow lever and withdraws the spent cartridge-shell.

Allen's gun (*M*) is double-barreled, and the breech-block is hinged at the side, swinging upwardly and laterally. It carries both firing-pins, and is locked shut by a latch.

Plate 17 gives views of the three arms recommended this year (1873) by the army commission at Springfield.

R is the Springfield arm, having a breech-block hinged to the upper edge of the barrel and swinging upward and forward. The indorsement of the board, as the best all things considered, entitles it to an honorable place in the series of examples. *R* is a side view of the gun, with the breech-block *d* thrown up; *a* is the bottom of the receiver, *c* the breech-pin, with its circular recess to receive the cam-latch *f*, which locks the breech-block in place; *g* is the cam-latch spring, *h* is the firing-pin, which transmits the blow of the hammer to the priming of the cartridge, and is pressed back by a spiral spring after the delivery of the blow; *j* is the cartridge-shell ejector, *k* its spring; *l* an incline which tips up the ejected shell so as to throw it out of the receiver.

R' is a top view of the gun with block closed. R^2 is a longitudinal vertical section with the breech-block closed. The dotted lines show the block raised.

The breech-block is raised upward and forward in the act of opening by a thumb-piece *m*, which releases it by turning up the cam-latch out of its recess in the breech-pin. When fully open, it discloses the chamber, or rear end of the barrel, ready for the insertion of the charge contained in a copper cartridge-case, holding seventy grains of musket-powder, and firing a bullet $\frac{45}{100}$ of an inch in diameter and weighing about 400 grains. When the breech-block is closed, it is held down and braced against the effort of the heaviest charges by the cam-latch, which flies

BREECH-LOADING FIRE-ARMS.

PLATE XVIII. *(American and Swiss.)* *See page 853.*

Digitized by Google

into place in closing. The piece is fired by the ordinary side-lock taken from the old muzzle-loaders. In opening the piece after firing, the breech-block strikes the lump on top of the extractor, and revolves it so as to carry the now empty cartridge-shell to the rear. After passing a certain point, the spiral spring in front of the extractor is released, and accelerates its motion, so that the cartridge is thrown sharply against the beveled surface of the ejector-stud, by which it is deflected upward and expelled from the gun.

S S' are two views of the Elliot carbine recommended by the same board for trial in the field, as exhibiting "remarkable facility of manipulation in requiring but one hand to work it." This arm has a breech-block hinged to the breech-pin and operated by the hammer. Fig. *S* shows the gun in loading position, and *S'* in the position "ready to fire." After firing, the hammer *d* is pulled back to the position shown in *S*, and in so doing draws by the yoke *b* upon the breech-block *a*, to which it is pivoted at *c*. This pulls down the front end of the breech-block, exposing the rear of the barrel for the insertion of the cartridge. Having done this work, the pin *e* of the yoke slips out of the socket *f* into the lower portion of the groove, while the lower branch of the yoke engages over the pin *g*, so that when the hammer is again pulled back, the breech-block is pushed up again into the position shown at *S'*, where the hammer is on full cock and the arm ready to fire. *h* is a strap which works the retractor, so that the shell is ejected as the breech-block is pulled down. *S* shows the cartridge-ejector pulled out; *S'* shows it in its bed. One pull on the hammer depresses the breech-block and ejects the empty shell; another pull closes the breech-block and puts the hammer in position for firing; a pull on the trigger fires the arm.

T T' are two positions of the Ward-Burton gun, which is on the *bolt* principle, like the Prussian needle-gun and the French Chassepot. This gun, in its magazine form, was also recommended "for farther trial in the field." This gun, having been fired, is opened by raising the handle *a* of the bolt and withdrawing it directly rearward; the position is shown in Fig. *T'* of Plate 17. As the cartridge-shell is pulled out by the spring-hook on the upper edge of its flanged rim, the pin which rests against its lower portion comes in contact with the front end of the trigger-pin, which tips it up and throws it out of the receiver. Another cartridge is then introduced by hand or by automatic devices from the magazine, and pushed into the bore of the gun by the longitudinal forward motion of the bolt. Near the head of the bolt is seen a part of the sectional screw which engages with a corresponding section within the gun when the piece is closed, and the handle turned down into place, so as to support the bolt against the force of the discharge. The firing-pin is an axial spring-pin released from the bolt by a downward pull by means of the trigger and lever. Fig. *T* is the position "ready to fire," the driving-spring being condensed and ready to act. Fig. *T'* shows the bolt withdrawn and the cartridge tumbling out. When the bolt is withdrawn, the sleeve of the firing-pin is so far retracted that a shoulder catches behind the trigger. When the bolt is pushed home, driving the cartridge into the barrel, it leaves the shoulder of the firing-pin resting against the trigger, as shown in Fig. *T*.

Plate 18 shows three other American forms of fire-arms, and the Swiss adopted pattern, which is a bolt needle-gun.

U U' are two positions of the Remmington gun; the left-hand figure is "fired," the right-hand "ready to load." The breech-block *b* swings upon a strong pin within a mortise of the stock. *c* is a tumbler which braces the breech-piece against recoil at the time of firing, and forms a part of the hammer which strikes a firing-pin, which passes through the tumbler and is driven against the cap or part of the cartridge-case containing the fulminate.

The breech-piece *b* and tumbler *c* are so formed that when the former is closed the rounded upper portion of the tumbler works in a concavity in the back of the breech-piece, as shown in Fig. *U*, and when the hammer is drawn back to half-cock or full-cock the rounded back of the breech-piece works in a concavity in the front of the tumbler, as shown in Fig. *U'*. This mode of matching the breech-piece and tumbler prevents the possibility of the hammer falling until the breech-piece is perfectly closed, and so obviates the possibility of premature explosion of the charge. The extractor, by which the discharged cartridge-shells are drawn out from the chamber of the barrel, works between the receiver and the breech-piece, and is operated by the opening movement of the latter. The breech-piece is opened by the thumb-piece. A guard-lever *d* prevents the trigger being drawn when the breech-piece is open.

W W' are two views of the Dodge breech-loader, shown as a double-barreled breech-loading fowling-piece. *W* is a perspective view, and *W'* a sectional view. The barrels are hinged to the front end of the stock, so as to tilt upwardly at the rear and nearly balance upon the hinging-point, the motions being made by means of the pivoted lever *d*, which laps over the trigger-guard and locks the barrels in firing position by engagement of a hook *c* with a pin passing through the lug *g*. The front end of the lever extends beyond the pin on which it turns, and works in a slot in the center of lug *g* beneath the barrels, which it serves to elevate and depress. As the barrels are elevated, the front end of the lever strikes against a projection on the stem of the extractor, and retracts the spent cartridge capsule. The frame *e* is made of a single piece of metal extending from the front, where the barrels are hinged, to the grip in the rear of the breech; and the locks are fitted in recesses therein, dispensing with separate lock-plates. The locks are "rebounding," that is, they go forward and fire the cap and return to half-cock. The hammers draw back the firing-pin when full-cocked. The barrels are adjusted on the frame, and wear is compensated by means of the block *b*. In use, the left hand need not be moved from where it is in firing; the breech is brought under the right arm, the lever thrown down, fresh cartridge inserted, the lever returned, the hammer cocked, and the piece is ready to fire.

The gun adopted by the Swiss Federal government has the magazine and cartridge-carrier of the Winchester, with the needle-exploder and bolt breech. The large figure is a longitudinal central section; *x* is a perspective view of the bolt, firing-pin, and lever detached; x^1 is a view of a piece of the breech-cylinder; x^2 is a view of the cartridge-carrier detached. The motions are as follows: the lever *a* is raised, rotating on the firing-pin *b*, and cocking the latter by the pressure of a cam upon the transverse trigger-bar *c*; the bolt is then drawn back, carrying the firing-pin and the hook, which retracts the spent cartridge; the motion eventually rocks the bell-crank lever *d* and raises the carrier *e*, which brings another cartridge in line with the barrel. The bolt *h* is then pushed back, pressing down the carrier *e* and driving the cartridge into the barrel; a partial rotation of

Digitized by Google

the bolt, by means of the lever *a*, locks it firmly by the catching of studs *f* on the bolt behind lugs *g* on the breech-cylinder. The firing-pin has remained on cock since the first motion of semi-rotation of the bolt, and is now pulled off by the trigger. The combination is known as Vetterlin's.

Y' is the Henry magazine rifle, now known as the Winchester repeating-gun. It may be used as a single-loader or a repeater. As a repeater, the motion of the lever *a* withdraws the spent shell of the previous charge, raises the hammer, recharges the gun, and relocks the breech mechanism. The magazine contains seventeen cartridges, which can be discharged in as many seconds. With single loading, the cartridge is placed in the carrier-block, and a single motion puts it in order for firing. The cartridges are placed in the magazine by pressing them through the trap *b* on the right-hand side of the gun, the magazine being easily filled while the gun swings at the side. They are fed from the magazine into the carrier-block by a spiral spring.

Y is a section of the gun immediately after discharge; *c* is an empty shell; *d* one in the carrier-block; *e*, one in the magazine; by the forward motion of the lever *a* the links take the position shown in *Y'*, the piston *g* is withdrawn, raising the hammer to the full-cock, and extracting the empty shell *c*, which is thrown upward at the same time the carrier-block *h* with the carriage which it contains is raised by the lever *i* placing the cartridge opposite the chamber. This position is seen at *Y''*. The returning motion of the lever drives the piston forward, leaves the hammer at full-cock, forces the cartridge contained in the carrier-block into the chamber, drops the carrier-block to receive the following cartridge from the magazine, and places the arm in readiness to be fired.

The United States has adopted the Springfield.

England adopts Snider's improvement on the Enfield.

France, the Chassepot.

Belgium, the Albini.

Holland, the Snider.

Turkey, the Remington and Winchester.

Austria, the Wanzl.

Sweden, the Hägstrom.

Russia, the Laidley and Berdan.

Switzerland, the Winchester.

Portugal, the Westley-Richards.

Prussia, the needle-gun. The well-known form shown at *C*, Plate 14, has been superseded by the *Mauser* gun. See NEEDLE-GUN.

The breech-loaders purchased by the American government between January 1, 1861, and January 30, 1866, were of number and kind as follows: —

Ballard	1,500	Maynard	20,002
Ball	1,002	Palmer	1,001
Burnside,	55,567	Remington	20,000
Cosmopolitan	9,342	Sharps	80,512
Gallagher	22,728	Smith	30,062
Gibbs	1,052	Spencer	94,156
Hall	3,520	Starr	25,603
Joslyn	11,261	Warner	4,001
Lindner	892	Wesson	151
Merrill	14,495		

CLASSIFICATION OF BREECH-LOADING FIRE-ARMS PATENTED IN THE UNITED STATES.

Class A. Movement of Barrel.

1. *Sliding longitudinally forward.*
2. *Tilting*
   - (*a.*) Down at muzzle and up at breech.
   - (*b.*) With muzzle upward.
   - (*c.*) On hinged joint.
3. *Swinging laterally on vertical pin.*
4. *Rotating on parallel longitudinal pin.*

Class B. Movement of Breech-block.

1. *Sliding longitudinally backward*
   - (*a.*) Operated by a lever.
   - (*b.*) Withdrawn by hand by a thumb or spring catch, or by a handle, and fastened by a bayonet-catch.
2. *Swinging or tilting.*
   - (*a.*) Hinged to top of barrel and turning upward and forward.
   - (*b.*) Hinged to side of barrel and swinging laterally forward.
   - (*c.*) Hinged beneath barrel and swinging forward and downward through mortise.
   - (*d.*) Swinging on centers or trunnions.
   - (*e.*) Hinged at rear, to swing upward and backward.
   - (*f.*) Hinged at rear and swinging laterally.
   - (*g.*) Hinged at rear and swinging downward and backward through mortise.
3. *Sliding transversely through mortise*
   - (*a.*) Moving vertically.
   - (*b.*) Moving laterally.
4. *Swinging or rotating laterally*
   - (*a.*) On a longitudinal pin or hinge.
   - (*b.*) Having the form of a rotating sleeve.
5. *In form of a faucet or spigot*
   - (*a.*) Having chamber in the faucet.
   - (*b.*) Having chamber in the barrel in front of faucet.

Class C. Revolvers.

1. *Chambered cylinder revolving on parallel axis*
   - (*a.*) Behind a barrel; cylinder charged in front.
   - (*b.*) Behind a barrel; cylinder charged at rear.
   - (*c.*) Cylinder without other barrel ("pepper-box").
2. *Chambered cylinder revolving on vertical axis, behind a barrel.*
3. *Chambered cylinder revolving on horizontal transverse axis, behind a barrel.*
4. *Revolving hammer acting on several stationary barrels.*

For illustrations of revolvers, see under the head REVOLVER.

Fire-ar'row. An arrow carrying a combustible for incendiary purposes.

Fire-back. The back-wall of a furnace or fireplace. It is frequently of fire-brick, in order to protect the iron walls of the furnace, but is sometimes of iron ribbed, partly to protect and stiffen it and partly to allow access of air close to it. Sometimes the fire-back is perforated to admit air at that point; or it may be hollow, and form a heater for water for household purposes.

Fire-ball. A projectile of oval shape, formed of a sack of canvas filled with combustible composition. They are thrown into an enemy's works for the purpose of lighting them up, and are loaded with shells to prevent them from being approached. A wrought-iron bottom is attached to the bag to prevent breakage when discharged.

Fire-bal-loon'. 1. A balloon whose ascensional power is derived from a body of heated air rising from a fire beneath the open mouth of the bag. Montgolfier's balloon was of this kind. See BALLOON.

Fig. 1985.

Fire-Bell.

2. A balloon sent up at night with fire-works.

Fire-bar. A grate-bar in a furnace resting on a frame, called the *fire-bar frame*; inside the *fire-box*. See GRATE-BAR.

Fire-bas'ket. A portable grate or cresset.

Fire-bell. A fire-alarm bell. One designed to indicate by a definite number of strokes the district or locality in which a conflagration is prevailing.

The illustration shows a striking-apparatus consisting of a series of levers connected with the clapper of the bell, and operated by a person stationed in a lookout-lantern above.

The signal-bells are now usually sounded by electricity. See FIRE-ALARM TELEGRAPH.

Fire-board. A board to close a fireplace in summer.

Fire-box. The fire-chamber of a locomotive-boiler. It is jacketed with a water-chamber to prevent radiation of heat. The fire-box door may also be double and have a circulation of water through the hinges. A *partition* in the box sometimes divides the fire-space into two parts, and, being full of water, increases the fire surface.

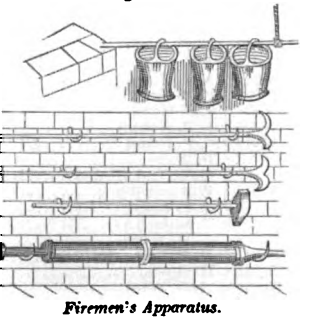
Fire-box stays are rods which prevent the crushing down of the top of the box by the pressure of steam.

Fire-brick. A brick of refractory clay for lining furnaces, ovens, etc. Fire-clay is a nearly pure silicate of alumina.

Fire-bridge. A plate or wall at the back of the furnace to support the ends of the grate-bars and prevent the fuel being carried over. It also serves to give an up turn to the flames against the bottom of the boiler.

Fire-buck'et. One made of canvas, leather, or wood, and kept in readiness for emergencies. On board ship, a fire-bucket has a sennit lanyard of a length regulated to reach the water alongside, from the station whence the fire-bucket is to be thrown overboard to be filled.

Fig. 1986.



Firemen's Apparatus.

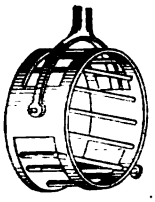
The illustration shows the firemen's apparatus of old time, — buckets, fire-hooks, hammer, and squirt.

Fire-cage. A skeleton box or basket of iron for holding lighted fuel. A *cresset*.

The form illustrated was invented by Dr. Franklin. The cage turns upon axes supported by a crotchet fixed on a stem. The stem may set in a step in the hearth, when used as a domestic grate,

Digitized by Google

Fig. 1987.



Fire-Cage.

or the fire-cage may be used for a beacon light. The fuel is introduced after withdrawing the upper bar, and when the kindling on top has begun to burn well, the cage is upset, bringing the lighted kindling to the bottom.

Fire-cham'ber. (*Puddling.*) The chamber at the end of the puddling-furnace, whence the flame passes to the reverberating chamber where the charge is placed.

Fire-cock. A street plug for attachment of hose for extinguishing fire, or for other municipal purposes.

Fire-damp A-larm'. One which indicates the presence of dangerous quantities of gas or fire-damp in coal workings. A *gas-alarm* or *gasoscope.*

Fire-dog. An ANDIRON (which see).

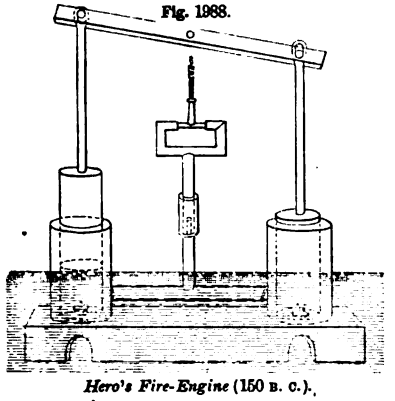
Fire-door. The door of a furnace; feeding and stoking are usually performed at the opening.

Fire-en'gine. A form of pump for throwing water to extinguish a fire.

The original fire-engine was probably a large squirt, the piston being worked by manual pressure, the barrel being filled from a tub after each discharge. In this form it existed till a late day.

The oldest known engine is described in the *Spiritalia* of Hero, about 150 B. C., and the description might stand for the ordinary form of hand-engine used at the present day. The drawing is made from

Fig. 1988.



Hero's Fire-Engine (150 B. C.).

the description. The engine had two single-acting pumps worked by one beam by means of brakes. The streams united in a common discharge-pipe passing up a trunk in which was an air-chamber and out at a nozzle which was capable of being presented in any direction.

The fire-brigade of Imperial Rome was a company of six hundred freedmen, organized by Augustus Cæsar, A. U. C. 732. A fire-preventive committee, consisting of seven freedmen and a president of the equestrian order, was organized fifteen years afterwards, say B. C. 7. Augustus gave the form stated to a preëxisting organization.

We do not find in any Roman writer a description of a machine so perfect as that of Hero. The *sipho* of the Romans is referred to by Pliny in a letter to Trajan: he states that the people of Nicomedia were too lazy to put out a fire in that city, and that they had no *sipho.* Strabo alludes to the *siphones,* which it appears were kept in a house, in preparation for accidental fire. Apollodorus, the architect of the bridge of Trajan across the Danube, mentions the *sipho.* Its construction seems to be unknown. Apollodorus recommends a leathern bag of water with hollow canes for discharging-nozzles.

The first notice of the modern fire-engine is in the Chronicles of Augsburg, 1518, which speaks of the "water-syringe useful at fires." They were mounted on wheels, and worked by levers. Similar devices are referred to by Lucar, 1590; Greatorix, 1656; and Morland, 1670.

The fire-engine of Nuremberg described by Caspar Schott, 1657, was of a different character. It was mounted on a sled 4 × 10 feet, and drawn by two horses. It had a cistern 2 × 8 feet and 4 feet deep, in which were two horizontal cylinders. The brakes were worked by twenty-eight men, and the combined streams from the cylinders issued at a one-inch orifice, and reached a hight of 80 feet.

An English patent appears of the date of 1632 to Thomas Grant, and one to John Van der Heyden (or Heide), of Amsterdam, 1663. He is credited with having brought the machine to the present modern form of hand-engine. The brothers Van der Heyden appear to have been the inventors of the leathern hose in detachable sections.

In 1699, a patent was granted in France to Duperrier for a *pompe portative* for extinguishing fires; to this Perrault added the air-chamber. Papin also adopted it. Hooks and fire-ladders must be assumed to have been long in use, but come into historic notice about this time. Fire-plugs were laid down in the streets of London in 1710; previous to that time the water was carried in buckets and poured into the fire-engine reservoirs.

Much attention was drawn to the matter of fire-engines by the disastrous fire of London in 1666, and an act of Common Council was passed shortly after the event, compelling parishes and incorporated companies to maintain an efficient supply of "*buckets, hand-squirts,* and *fire-engines.*"

If we may judge by the description in Clare's "Motion of Fluids," 1735, some of the features of the Continental engines had not yet been received in England. He states: —

"Engines for extinguishing fires are either forcing or lifting pumps, and, being intended to project water with great velocity, their effect in great measure depends upon the length of their levers and the force with which they are wrought. A common squirting-engine, constructed on the *lift* principle, consists of a large circular cistern, like a great tub mounted on four small solid wheels. A perforated cover was fixed inside the cistern about three feet from the bottom. In the center was fixed a lifting-pump, to the piston-rod of which was attached a cross-tree carrying two vertical connecting-rods, which were simultaneously worked up and down by manual labor by means of handles on opposite sides of the machine. During the downward motion of the piston a quantity of water passes through the valve on to its upper side, and, when the piston ascends, this water is projected with great velocity through a branch pipe provided with a flexible leather joint, or by a ball-and-socket motion, screwed on top of the pump-barrel. Between the strokes the stream is discontinued. The cistern is supplied by water-buckets."

Towards the close of the seventeenth century the double-cylinder portable pump with air-chamber was introduced into England by Newsham; single-cylinder engines, like the modern garden syringe, being used in France and Germany, and credited to Duperrier and Leupold respectively.

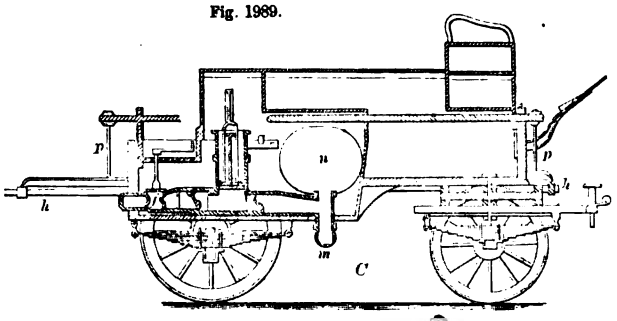
The Newsham engine was improved from time to time, retaining its main features, and was still in use in London till 1832, when it was superseded by

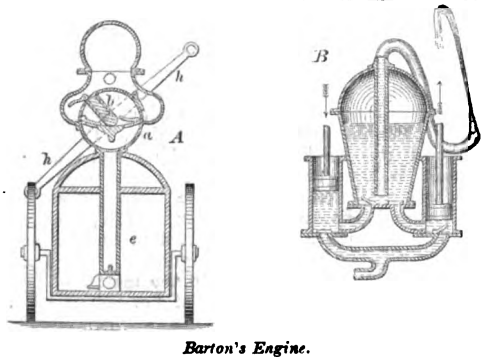
Digitized by Google

a more compact form, which was adapted to be drawn by horses, and from this period dates the efficient fire-brigade system of London.

Newsham's fire-engine was a side-brake double-cylinder engine, mounted on four wheels, and with an air-chamber, goose-neck, and suction-pipe. The work on the brakes was assisted by men on the box, who threw their weight upon treadles on the pump-levers. Pumps were single-action force-pumps, worked by chains passing over segments on the pump-levers. The engine was perhaps the first successful fire-engine, and Newsham did very well by it. His patent was extended for a second term.

Fig. 1989.





Barton's Engine.

The engine which eventually superseded that of Newsham was made, rather than invented, by Simpkin, and patented in 1792.

The main improvement was in compactness and adaptation to traveling with speed to the spot where its services were demanded. The valves were contained in separate chambers, instead of being placed in the cylinders and air-chamber. By this means they were easily reached, without the disconnection of the main portions of the pump.

Another form of fire-engine was invented by Bramah, 1793, improved by Rowntree and eventually by Barton. The engine of the latter (*A*, Fig. 1989) was on the vibrating principle. To the levers *h h* was attached a radial piston *b*, which oscillated in the cylindrical chamber. As the piston moved in one direction, a valve beneath this piston opened to allow water to pass from the cistern *e*, and the water in front of the piston was forced through the valve-way above it into the air-chamber and passed out at the eduction-pipe to the hose. The difficulty with this engine, as with the rotary steam-engine and other pumps with annular chambers, was to keep the end and sides of the piston effectually packed.

B, Fig. 1989, shows the principle of the modern hand-worked fire-engine, which has two single-acting cylinders with induction-valves in the branches of a pipe which connects with the cistern or water-main; and eduction-valves in pipes which discharge into an air-chamber, whence the water passes by a hose to a nozzle.

C is the English form of hand fire-engine which has brakes *h* on side-levers *p*. The suction is united at *f*, and the discharge is at *m*; *n* is the air-chamber.

Steam-power for extinguishing fires was in use in manufacturing establishments many years before it was employed on portable machines. Every factory of any pretensions had its steam-driven pump, with hose and other attachments calculated to reach every portion of the establishment. About the year 1830, Captain Ericsson, then of the firm of Braithwaithe and Ericsson, London, England, built and exhibited a portable steam fire-engine. In 1842 or 1843 he produced a similar engine in New York City, and it was tested, but never brought into regular service. The engine delivered 9,000 gallons an hour to a hight of ninety feet through a $\frac{7}{8}$-inch nozzle. It was ignited at the station, and drawn by horses to the fire. The time occupied in getting up steam was eighteen minutes. The motion of the wheels worked the bellows to blow the fire in the furnace.

Cincinnati was the first city to adopt the steamer as a permanent portion of its fire-department force.

This was due to the inventive and constructive skill of the brothers Latta and Mr. Abel Shawk, supplemented by the foresight, persistence, and tact of Mayor Miles Greenwood, all of that city.

The metropolitan fire-department of New York City numbers 34 steamers of about 50-horse power each, equal to 185 men, or in the aggregate 6,290 men; while the actual number of men employed, even adding the 12 hook-and-ladder companies, is only about 550; thus relieving 5,740 men from the labors, dangers, and exposure of the fireman.

The Cincinnati engines and system are excelled nowhere, and have been copied into the principal cities of the world. The steamer "Citizens' Gift," one of the earliest of the Cincinnati steam fire-en-

Fig. 1990.

English Steam Fire-Engine.

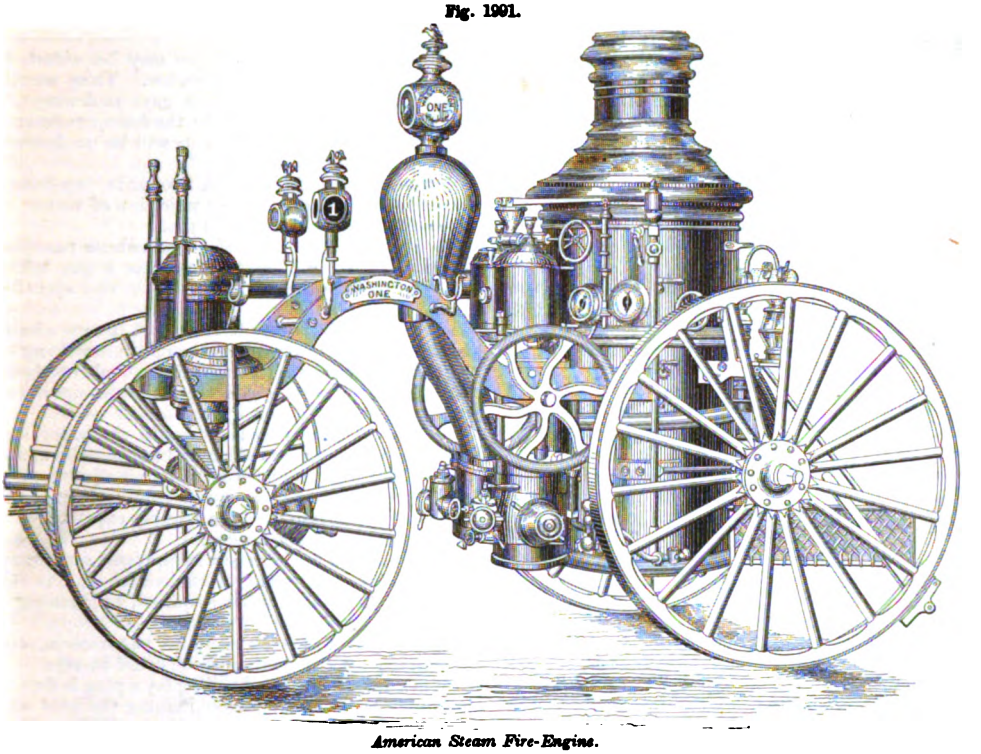
Fig. 1901.



American Steam Fire-Engine.

gines, was built in 1853, and thirteen years afterward gave the following record: Time of raising steam, three minutes and forty seconds from the time the torch is applied until water is thrown from the nozzle; size of nozzle, 1½ inches; distance thrown, 310 feet, measuring from the end of the nozzle to the place where solid water fell; size of steam cylinder, 10 inches bore, 24 inches stroke; pumps, 6 inches bore, 24 inches stroke; double engine-cranks at right angles; large air-vessels, connected together; length of hose, 100 feet; steam, 100 pounds to the square inch; pressure on water cylinder, 240 pounds to the square inch; speed of engine, 110 revolutions; 220 strokes of pumps; grate surface, 16 feet; heating surface, 560 feet.

The chemical fire-engine is one on the principle of the fire-extinguisher (which see), in which, by throwing a body of sulphuric acid on to an alkali, a body of carbonic acid is generated and ejected into the flame, usually in combination with a spray of water which is ejected from its reservoir by the pressure of the gas, or by the play of the pump-brakes.

In connection with this subject it may be stated that the rate of insurance by land and sea among the Hindoos was left to the custom of the trade, according to the risk. — *Institutes of Menu* A. D. 880.

Nicholson states that fire-insurance offices were first introduced under the reign of the Emperor Claudius.

The "Hand in Hand" Fire Insurance Company was the first established in London, 1696. The "Sun" Fire Insurance Company was established in 1700. *Marine* insurance had long been common in Venice. The "Amicable" *Life* Insurance Company of London was chartered in 1706.

Fire-insurance offices established in Paris, 1745.

Fire-es-cape'. Fire-escapes are divided into three classes: —

Ladders.

Portable escapes.

Carriage-escapes.

1. Fire-ladders are made of several lengths, to reach second, third, or fourth story windows, and are mounted on a suitable carriage for transportation. The upper ends are usually provided with hooks which catch against the building, on a window-sill, cap, coping, or cornice, and give some degree of security to the ladder.

Another form of the ladder is made of several sections, which may be united to form a ladder of any length required. The sections are united by tubular sockets or clasps.

Another form is that in sliding sections of gradually decreasing width, so that when packed the different sections form a nest of parallel lengths. The sections are slipped on each other by cogs and pinion or by tackle.

2. Portable escapes are those which are contained in a compact form to be raised and placed in position in an emergency.

Among these are —

A *knotted rope.*

Rope-ladders kept within the house and provided with a means for lashing to some stationary object in a room or on a staircase, while the ladder itself depends from the window,

Wire or *chain ladders*, on the same principle, are compact and strong, not subject to decay or to be burned away when in position.

Both descriptions of ladders are also made with grapnels, so arranged as to be elevated from the outside and attached to a window-sill for the escape of the occupants of the house.

Slings are used, and forms of tackle.

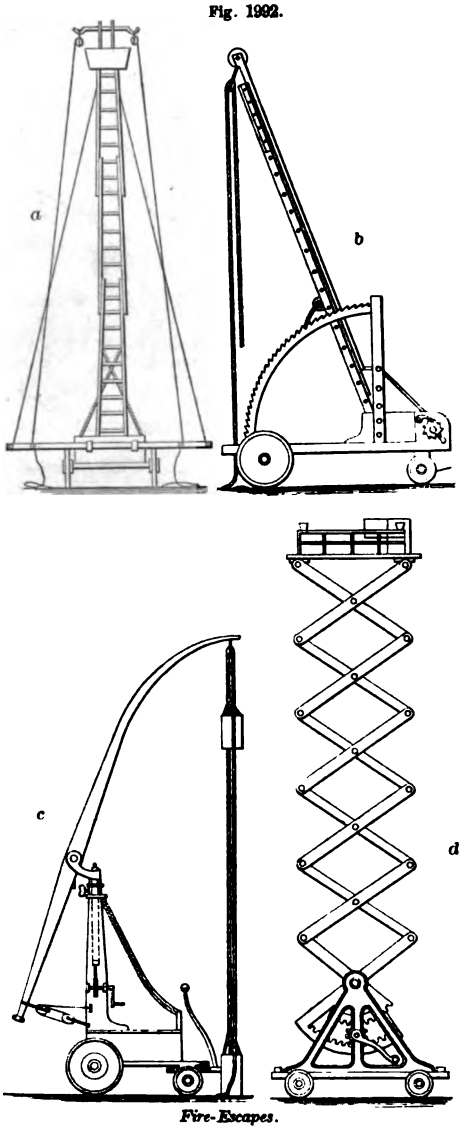
One sling has the bight of the rope secured be-

Digitized by Google

neath the window-sill and the ends held apart by persons in the street. A clasp is buckled to the person and slides on both ropes, the descent being checked by the divergence of the ropes.

Of forms of tackle, one is the single whip, the person sitting in a sling at one end and veering out the fall through his hands. In another form the person sits in a sling suspended from the bight of a rope, and lowers himself by allowing the rope to

Fig. 1992.



Fire-Escapes.

veer through the holes of a block, like a euphroe. It is a tackle with dead-eyes instead of sheaves. It is mentioned in Rees's Encyclopedia.

The Edinburgh (Scotland) fire brigade is furnished with cross-bows and three-ounce leaden bullets to which are attached fine cords 130 feet long. The bullet is fired over the house, and persons in the rear of the building pull at the cord to raise a stronger one from which a chain or ladder or escape is suspended. The men are regularly trained to the exercise.

Of carriage-escapes four types may be cited, but room cannot be spared for a treatise. They may be called the *extension-ladder* with guys and stays, *a*; the *ladder with segment rack*, *b*; the *boom* or *crane*, *c*; and the *lazy-tongs*, *d*. The cuts will be understood without lengthy description.

Fire-ex-tin'guish-er. A portable apparatus for extinguishing fires either by ejection of water, saline solution, or carbonic-acid gas.

1. The vessel contains chemicals whose reaction, when brought into contact, releases a gas which presses upon the surface of the water and ejects it at the nozzle.

a. The chemicals may be contained in two chambers; inversion of the apparatus or the breaking of a bottle of acid mixes the ingredients, and the chemical reaction evolves a gas which presses upon the water.

b. The chemicals may be mixed in the water and generate the pressure which is immediately available when the nozzle is opened and air admitted.

c. The water is saturated with gas, in the manner of the soda-fountain, so as to forcibly expel the water when the outlet is opened.

d. A body of mechanically compressed air is contained in a compartment of the vessel, and is admitted to the water, when required, by turning a stop-cock.

2. *a*. The receptacle contains two vessels, one of which is usually a salt and the other an acid.

When it is to be brought into play a plug is driven in, which breaks the bottle containing the acid and allows it to flow over the salt of soda, potash, magnesia, or ammonia, as the case may be, the evolved carbonic-acid gas flowing in volumes from the nozzle of the vessel.

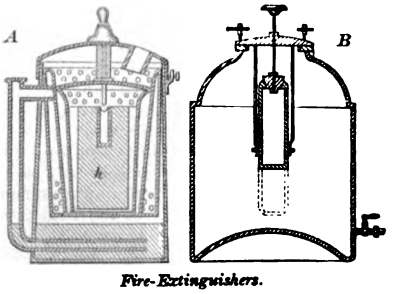
The acid used is usually sulphuric, but hydrochloric and tartaric are occasionally employed.

The salt is a carbonate of an alkali; soda, potash, ammonia, or magnesia being employed, as just stated. Other combinations of salts, chlorides, and sulphates, are employed.

In some of the apparatus, water is ejected along with carbonic acid; in others, sufficient heat is generated to evaporate the water, and steam is ejected with the gas.

b. The vessel contains inflammable substances

Fig. 1993.



Fire-Extinguishers.

which generate carbonic acid when air is admitted, and eject the gas in volumes.

The chemicals used are phosphate of lime, nitrate and chlorate of potash, carbon, sulphur, and various other materials in a multitude of combinations.

There are perhaps sixty patents for various forms of the *fire-annihilator*. The devices particularly refer to the modes of construction, the acid and alkali

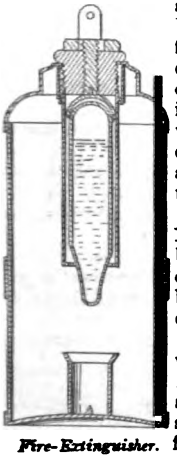
Digitized by Google

chamber, the modes of precipitating the former upon the latter and availing the product. The Phillips *fire-annihilator*, so called, patented in 1849 and shown at *A*, has a compound of sugar and chlorate of potash so placed as to receive the contents of a bottle of sulphuric acid which is broken by striking a plug on the top of the can when a fire occurs. The mass of salt and sugar *h* is in the inner chamber, and the vial of acid imbedded in it, so as to be broken by a blow on the central plunger, when the lid is taken off for that purpose. Around the perforated case containing the filling *h* is another one, and that is in a third, between which and the outer one is a body of water. The carbonic acid produced by combustion passes out of the top of the machine, meeting, on its passage out, with the water which is raised in the side pipe by the pressure and heat of the combustion in the can, thus saturating the gas.

The — so-called — *American* fire-extinguisher has a cylinder containing bicarbonate of soda in solution, and an interior tube, containing crystallized tartaric acid, the whole being hermetically closed, but a communication left at the bottom of the tube, through which a reaction takes place, gradually converting the bicarbonate into tartrate of soda, and liberating the carbonic acid. This reaction being complete, the apparatus is ready for use, and on opening a cock at the bottom, the contents can be violently ejected through a short hose.

The *Gardner* consists of two cylinders, in one of which is diluted sulphuric acid, and in the other the aqueous solution of bicarbonate of soda. When the apparatus is required for use, connection is made by opening cocks between these two cylinders and a drum below them, into which the liquids flow, and where the carbonic acid is liberated, and the necessary pressure acquired to throw a jet through the hose.

Fig. 1994.



Fire-Extinguisher.

The machine shown in Fig. 1994 contains acid in a glass bottle, which is shattered by dropping upon a stud when forced below the flanges of the tin cylinder which holds it.

The *National* has a glass tube which contains the sulphuric acid. It is protected from accidental shocks by a metallic tube which surrounds it, and which is perforated to permit the free passage of liquid through its walls. When the apparatus is to be used, a piston is screwed down upon this glass vessel, crushing it, and permitting its contents to escape.

The *Babcock* (*B*, Fig. 1993) contains the sulphuric acid in a leaden bucket, hung upon trunnions below its center, so that, if set free, the bucket immediately turns upside-down. It is kept rigidly upright, however, by a stopper attached to a rod passing through the cap of the apparatus. This stopper also completely prevents communication between the acid and the alkali. When the extinguisher is to be used, the stopper is pulled up by means of an exterior handle; the bucket instantly turns over, and empties itself into the liquid in the cylinder.

In another form, the machine is set in operation by tipping. Another is set in action by a fuse tipped with a substance ignited at 120° F., or some other degree, as may be thought desirable. The apparatus is mounted on a carriage to operate on a larger scale.

A different description of fire-extinguisher consists of an arrangement of pipes throughout a building, so arranged as to throw water into the apartments and on the walls, when the water is turned on. With some of these arrangements the water is contained in cisterns on the roof; in others the pipes are connected with the water-distributing mains of the town.

An early instance of the kind is the English patent of Sir William Congreve, dated February 7, 1809, and No. 3201. In it almost all the more modern devices of this kind are shown. The perforated pipes run along the cornices and ceilings, the showers or jets proceed from center to circumference and conversely. On the chandelier pendant rotates a rimless wheel whose spokes distribute jets of water.

The apparatus is actuated by the heat of the room by means of fusible matters, such as wax which melts at 92° F., or a trinary alloy of lead, tin, and bismuth, which melts at 190°. An arrangement is also described by which the rising of the column in the mercurial thermometer is made to set the apparatus at work.

The general discharge may be made by a person in any one of the rooms of the building so furnished.

A common form has a cistern on the roof, central vertical trunk, and radiating pipes with jet-holes. See Fig. 1982, under FIRE-ALARMS. Modern patents concern mere details.

Fire-fan. A small blast apparatus adapted to a portable forge, or one — say a locksmith's — which has small proportions.

Fire-gild'ing. The mode of gilding in which the gold is put on in the form of an amalgam and the quicksilver afterward driven off by heat.

Fire-guard. A wire frame placed before an open fire to arrest sparks and burning coals. See FENDER.

Fire-hook. 1. A large hook on the end of a pole for tearing down buildings on fire, or to arrest a fire.

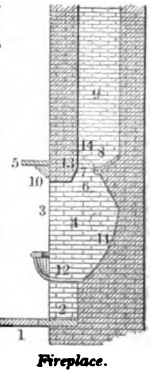
2. (*Steam-engineering.*) A kind of hook for raking and stirring the furnace fire.

Fire-i'rons. The implements for tending a fire. Poker, tongs, and shovel.

Fire-lad'der. These were introduced, as a part of the machinery for extinguishing fires, about 1672. They seem to have originated in the Netherlands.

Many and ingenious have been the devices for enabling the firemen to reach the scene of conflagration, and to pour in the jet of water at close quarters or into a part of the building which cannot be reached from the ground. Experienced men seem now to have settled down upon a set of ladders of varying length for different occasions, and mounted upon a long carriage drawn by a pair of horses.

Fig. 1995.



Fireplace.

Some forms of ladders are cited under FIRE-ESCAPE (which see).

Fire-lock. A musket or military rifle. See FIRE-ARM.

Fire-pan. A pan for holding fire. The pan which held the priming of the old flint-lock gun.

Fire'place. That part of a room in which the fire is built.

1, slab.
2, hearth.
3, jamb.
4, fireplace.
5, mantel-piece.
6, throat.
7, gathering.
8, funnel.

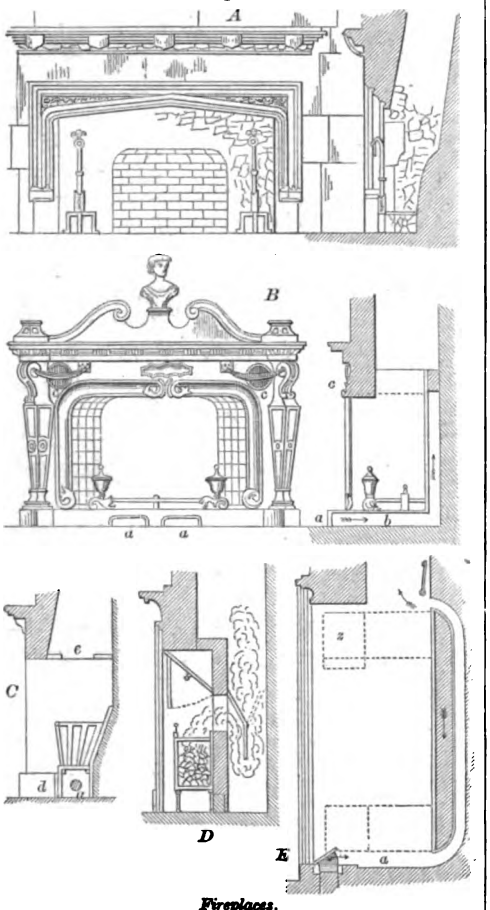
Digitized by Google

9, flue.
10, mantel.
11, back.
12, grate.
13, breast.
14, damper.

The earliest example of a fireplace cited in this work is that of Coninsborough Castle, in England, of the Anglo-Norman period. The mantels are constructed of flat arches. The example is adduced to show the earlier form of chimney, and perhaps the most ancient one in existence, anticipating by several centuries the first chimneys erected in Italy. (See CHIMNEY.) The fireplace (*A*, Fig 1996) in the hall of Vicar's Close, Wells, England, is an example of the fireplace of some centuries back.

Louis Savot, of the Faculty of Medicine at Paris (1579–1640), published a work on warming and

Fig. 1996.



Fireplaces.

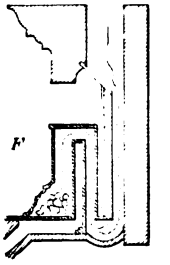
ventilation in 1624. His is the first recorded attempt at combining the cheerfulness of an open fire with the economy of an inclosed stove. Fig. *B* shows a front view and an elevation of his ingenious arrangement. The hearth, covings, and back were lined with thick iron plates three inches distant from the masonry. Air entered at *a*, passed along the chambers *b*, and entered the room at *c c*.

D is Prince Rupert's fireplace, somewhat celebrated in its time. It had a diving flue and false fire-back.

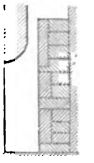
About 1658, Sir John Winter invented a coke furnace or fire-cage (*C*) which was placed on a close box about eleven inches high, in front of which was an opening *d*, fitted with a door, which always kept closed except when the ashes were being removed. A pipe *a* communicated with the external air, and was closed, when required, by a damper. When the valve was opened, a brisk draft urged the fire. The flue was closed by an iron plate or register at *c*.

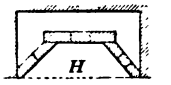
Cardinal Polignac, in 1715, published under the name of another man (Gauger's "Treatise on the Art of warming Rooms") an account of improved mechanical arrangements for fireplaces. This is shown at *E* in the figure. The hollow metallic case forming the back of the chimney is divided into three or more caliducts which are not in contact with the back wall. The jambs are iron plates, solid backed. The channel *a* conducts the external air into the caliducts, which form a fire-back, and the warmed air escapes into the room at *z*. He also introduced the parabolic sides.

Fig. 1997.

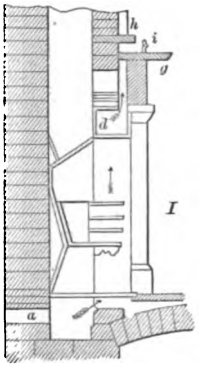


Rumford contracted the fire-chamber and throat, and inclined the jambs. See COVING.





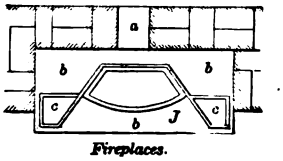
In 1745, Dr. Benjamin Franklin introduced a fireplace which he named the "Pennsylvanian," in which Prince Rupert's descending flue was combined with Polignac's caliducts. This is shown at *F*. (Fig. 1997.)



Count Rumford's improvements consisted mainly in the contraction of the chimney at the throat, the rounding of the breast-work, and the flaring of the covings, as illustrated in the accompanying plan and section *G H*. He preferred an angle of 45° for the covings.

Arnott also made himself a name in this line.

I J are a vertical section and plan showing an English tubular fireplace designed to warm a current of pure air derived from the outside, and direct it into the interior of a room; the air passes from the flue *a* to the under side of the hearth-plate *b* (shown in the plan), thence upward through the upright tubes at *c c* to a horizontal tube *d* (shown in the elevation), which has an opening through its entire length on the upper side, whence the hot air passes into the room, through the aperture *h i* over the mantel. The supply of air may be regulated by moving the strip *i* — which directs the air upward — nearer to or farther from the ledge *h*.

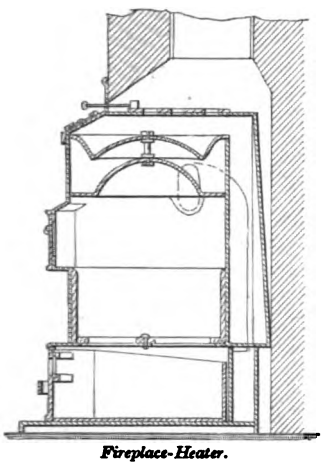


Fireplaces.

Fire'place Heat'er. A stove or closed grate set within or principally within the fireplace, and

Digitized by Google

Fig. 1998

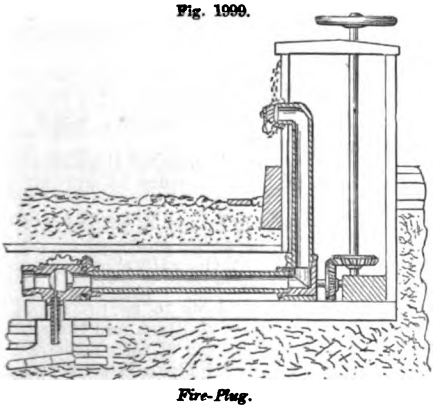


Fireplace-Heater.

serving to warm the room, the pipe discharging into the chimney. The kind known as the Latrobe is a base-burning fireplace-heater whose pipe passes up the brick flue to heat the air which passes between the pipe and the flue to the rooms above, into which it passes through registers.

Fire-plug. A device for connecting a fire or watering hose with a branch from a main. It usually consists of a screw nozzle to which the hose may be coupled, and a key and rod by which the valve is moved. In the example, at the point where the branch pipe is coupled to the main, the stop-cock is placed, and it is operated by gearing and

Fig. 1999.



Fire-Plug.

connecting shafts from a hand-wheel in the vicinity of the plug.

Fire-pot. 1. The box or pot in a stove which holds the fuel. Especially applied to a frustum of a hollow cone or conoid, used in base-burning and other heating stoves (which see).

2. A crucible. In various metallurgic operations the crucible is always termed the *pot*.

Fire-proof Fab'ric. The term *incombustible cloth* was originally applied to fabric made of asbestus, which was used among the ancients to a considerable extent. See ASBESTUS.

Cloth or wood impregnated with certain saline substances will not blaze. Borax, alum, and phosphate of soda or ammonia are recommended as most suitable for this purpose.

By treating cloth with graphite in a bath in which the mineral is suspended, and then subjecting it to the action of the electro-metallic bath, the cloth may be coated with metal.

The chemists who experimented on this subject by direction of Queen Victoria recommend "a concentrated neutral solution of tungstate of soda, diluted with water to 28° Twaddell, and then mixed with three per cent of phosphate of soda." Tissues dipped in this fluid may char or shrivel, but they will not blaze.

Woolen and ordinary stuffs may be treated with borax, alum, or soluble glass, but these cannot well be applied to the lighter descriptions, which are most liable to take fire.

A weak solution of chloride of zinc has long been employed by stage-dancers to render their dresses incombustible. M. Lunere recommends adding to the starch with which the material is done up, half its weight of chalk, and M. Patua proposes a solution of 4 parts borax and 3 sulphate of magnesia, in 20 to 30 parts water. By a new process, equal parts of chloride of calcium and acetate of lime are combined, forming crystals, which is mixed with the starch used in stiffening.

Though not strictly coming under the denomination of fire-proofing, an interesting fact is stated by M. Corne in a communication addressed to the Academy of Natural Sciences, that by previously dipping the hands in liquid sulphurous acid, they may then be immersed in melted lead or iron with perfect impunity. This is owing to the extremely volatile character of the acid, which has been made use of in the curious experiment of freezing water in a red-hot crucible.

Fire-proof Safe. One for the safe keeping of valuables for protection in case of the burning of a building in which they are placed. See SAFE.

Fire-proof Struct'ure. A vault, safe, or building proof against destruction by fire, either from the outside or by the burning of its contents.

The provision against outside fire is the usual object, but in fire-proof structures the internal floors or partitions must also be impenetrable by fire, to make the building technically *fire-proof*.

The principal portions of a building are the walls, floors, and roof, and several modes of constructing each have been proposed, to the end that they may be secure from fire.

The term *fire-proof building* is somewhat loosely applied, and may be held to mean, —

A building absolutely incombustible, such as one whose walls, floors, and roofs are of metal, stone, brick, or cement.

A building capable of opposing the access of fire from without, having walls, window shutters, and roofs which are incombustible from external flame and heat.

Among the first instances may be cited some government buildings, whose walls are of stone and brick, ceilings and floors of brick arches and pavement; or of metal, brick, and cement; rafters and roof-covering of metal, or metal and slate.

The Bogardus buildings of cast and wrought iron, and the Paxton buildings of iron and glass, are other illustrations of fire-proof structures, unless the amount of combustibles contained should be such that their conflagration will melt or crumble the material of which the building is constructed. Such was the case with a part of the Crystal Palace at Sydenham, the internal fittings of that portion, the louver boarding, and the furniture making a bonfire which melted the skeleton frame. Iron buildings in serious external fire exposure, or with combustible contents, are far from deserving the name of fire-proof, though they may resist a certain amount of scorching.

The usual mode of making fire-proof floors is to construct girders and beams of iron (see BEAM), supporting flat arches of brick, as in the U. S. Treasury, Medical Museum, and other government

Digitized by Google

buildings, or of a pavement of stone slabs resting on flanges of the beams. The ceiling in such a case may be of plaster on lath made of hoop-iron or wire-work riveted to the beams. See FLOOR; LATH.

Many European buildings are thus constructed, being filled above the arches with incombustible rubbish, and the tiled floor laid in cement thereupon.

Besides the projects for rendering materials fire-proof, a number of plans have been devised for adding to the security of a building, although the structure cannot be considered as actually *fire-proof*. Some of these may be mentioned.

The floors of some Edinburgh houses are of plank two and a half or three inches thick, grooved and tongued to each other or united by a fin of metal forming a tongue which runs the entire length. The planking is fitted air-tight to the walls, the object being to prevent the passage of fire, and depend upon the thickness of the flooring to hold fire at bay in a given part of the building, until the usual means of extinguishing it can be brought to bear. It is laid on iron joists. Cement on the upper and lower surfaces adds to the security. This is an excellent plan.

Another plan is to form the floors and roofs of hollow earthenware tubes and cement, resting upon joists or rafters, as the case may be. The tubes are made square in section. The floor has about one fifth the weight of stone. Frost's cement of levigated chalk, 2 parts; clay, 1 part; dried, broken, burned, and ground to powder. This is an approach to the pozzuolana, and is mixed with twice its quantity of sand and water, sufficient to form a mortar. See CONCRETE; CEMENT.

There are various concretes which may be made into slabs, capable of resting upon iron beams at the usual distance, and thus form a perfectly fire-proof floor.

It should be mentioned as an imperative necessity that the staircase should be absolutely incombustible, of metal or stone, or the two combined.

When a building has some of the *protections* against fire, without being absolutely *proof*, the stairs and hatchways must be inclosed in such a manner as not to be involved by a fire breaking out on any of the floors. Otherwise the vertical shaft forms the best possible means of communicating fire from one portion to another, especially if the fire be low down in the building.

Other plans are, —

Iron facing for walls; secured by anchors or studs. Iron skeletons filled with brick or concrete. Concrete or béton walls. Hollow tile walls. Iron frame with wire-work riveted thereto and covered over with plaster or concrete. See WALL, where many varieties are illustrated.

The means for fire-proofing the necessary openings, that is, the door and window ways, are by louvers, folding, sliding, swinging, and rolling shutters of iron. Some made double with intervening air-space; others made to close automatically by the increase of heat when exposed to fire.

Hartley's patent, 1775, consisted of a plan for sheathing wooden work with thin iron plates.

Earl Stanhope's plan was to pack all the interspaces of wood-work with incombustible material; preferably concrete.

Of other English plans of late date may be cited, iron joists with concrete filling and upper bed supporting the flooring. See FLOORING, where several varieties are shown.

Another plan is cellular joists of earthenware tubes imbedded in cement.

Loudon recommends a floor of cement with imbedded ties of wrought-iron rods, supported by pillars at intervals; and double sides of concrete supported by panels or lattice, leaving intervening spaces between walls.

In large fires, cast-iron is found to be a treacherous and destructible material, as was proved in Chicago, Boston, and elsewhere, fairly melting in the fire. Mr. Braidwood, of the London Fire Department, stated that iron columns were liable to give way suddenly, owing to the expansion and contraction by heat and jets of water. Mr. Mullett, the supervising architect of the Treasury Department, indorses the statement, and prefers sound oak timber to cast-iron, especially if it be treated with a liquid silicate.

Fire-proofing by rendering the timber of the structure incombustible has been frequently attempted. Payne's process consists of immersion in a solution of barium or calcium. Professor Fuchs of Munich recommends as a material for rendering wood fire-proof a composition of potassa or soda, 10 parts; siliceous earth, 15 parts; charcoal, 1 part, fused and formed into a water-glass and applied in solution. It forms a vitreous coating.

An English composition is as follows: Fine sand, 1 part; wood ashes, 2 parts; slaked lime, 3 parts. Grind in oil, lay on with a painter's brush, the first coat thin and the next thick.

Fire-proofing may be said to be accomplished when — 1, the building is of a material which neither burns, melts, cracks, nor crumbles with the heat. Well-made, homogeneous, and well-burned bricks are the best. Granite, marble, and sandstone perish by the heat.

2. Every opening communicating with the external atmosphere must be kept closed with fire-proof doors and shutters, not iron merely, which will buckle up, warp, and melt.

3. The walls must be of sufficient thickness, and should be built with an air-space to prevent the transmission of heat.

4. The joists should in no case be carried into the walls, but should be supported on corbel courses of brick, and connected with the walls themselves only by wrought-iron anchors.

5. The windows and doors to be protected, as before said, with fire-proof shutters, and the roof to be of slate or metal. The use of roofs composed of shingles, coal-tar, or other similar substances, should be prohibited by law in cities.

6. An isolated stone or iron staircase should reach every story, having fire-proof doors at each floor, and a line of water-pipes communicating with the mains in the streets or a cistern on the roof.

7. Partition-walls between houses rising above the roof. In the case of warehouses, as few openings through the party wall as possible, and these capable of being closed effectually.

A refinement upon the brick construction consists in using fire-brick with joinings of fire-clay, instead of mortar or cement; and the isolation of rooms instead of floors only is recommended in a report to the London Society of Arts; farther, to have no opening into the rooms except to external fire-proof corridors on each story; ascended by circular stairways. Doors, shutters, as well as walls, floors, and roof, to be of fire-brick, making each room an hermetically sealed vault.

For the purpose of extinguishing fire in any of the apartments, it is proposed to lay tubes of fire-clay in the spandrels of the building with small jet tubes, or pipes, commanding each room or corridor of the whole warehouse, so that the water can be turned on to any part required, to flood if necessary

Digitized by Google

the entire room. In such case the water would run down the walls to the floor, where, by a system of pipes leading to the main sewer, the proper drainage would be effected. It is also proposed to open and shut all the doors and shutters, and work all the cranes by machinery in another building to be under the supervision of a watchman, properly instructed, and competent to see that the system is in working order at all times. The same system of piping used to extinguish fires may also be used to cleanse the rooms, as occasion may require.

This system of protection against loss by fire, or rather mode of overcoming fire, by abundant ramifications of water-pipes throughout all the apartments and passages of a house, as well as upon the roof and walls, is thoroughly described in Sir William Congreve's English patents, No. 3201 of 1809, No. 3606 of 1812, and there seems but little to be added to his proposals where jets are by the turning of a plug caused to issue from center-piece, cornice, skirting-board, eave, comb, gable, and everywhere else. As this was before the era of water-mains, except in a few situations, the proposed supply was brought from cisterns on the roof or from pumps, and each floor or gallery had plugs by which the system of pipes of the respective stories were supplied.

A large flax-manufactory, to be run by steam-power, was erected about 1790, by Mr. Bage, at Shrewsbury, England. It was four stories high; the floors of brick arches were supported on cast-iron columns. The roof was also of iron.

Fire-reg'u-la'tor. A thermostatic device to open or close the access of air to the fire, or to govern the draft-area in the chimney, in order to urge or moderate the fire as it may sink below or rise above the desired point to which the thermostat is adjusted.

Fire-screen. 1. A fire-guard or *fender*.

2. A screen to place between a person and the fire to intercept the direct rays.

Fire-shield. A portable structure on wheels or on legs, used to protect a fireman on duty from the heat of a burning building, or to isolate a fire and prevent its spreading to adjacent buildings. It is usually a screen of sheet-iron supported by posts and stayed by guys.

Fire-ship. A vessel freighted with combustibles and explosives, and turned adrift so as to float among the vessels of the enemy, against a bridge or other object which may be burned by the fire or destroyed by the resulting explosion.

Fire-ships were used at the siege of insular Tyre.

By the Rhodians against the Syrians, 150 B. C.

In the action near Carthage, when the fleet of Basilicus was destroyed by Genseric.

In the naval warfare of the Knights of Malta and the Turks.

At the siege of Antwerp, 1585. By Sir Francis Drake against the Spanish Armada, 1588.

By the Greeks against the Turks, 1826.

The Chinese against the English in the villainous opium-war.

In 1760 they formed a regular portion of the British navy. As a distinct class of vessels, they are now discontinued.

They are particularly serviceable in defence and in attacking ships at anchor, and besides the skillful but ineffectual use of them by the Chinese, the instance may be mentioned of the fire-rafts which were launched by the Confederate forces against the approaching fleet of Farragut as he forced the passage of the Mississippi.

Fire-steel. A steel used in connection with a flint for striking fire.

Fire-stop. The fire-bridge at the back of a furnace; so called because it prevents coals being pushed over.

Fire-sur'face. (*Steam-engine.*) The area of surface of the boiler which is exposed to the direct and radiant action of the flames.

The heating-surface of a boiler is made up of the *fire-surface* and *flue-surface*.

With an average boiler 15 feet of heating-surface of the boiler are allowed for each horse-power. The Cornish engine has a much larger heating-surface per horse-power; as high as 60 feet being sometimes allowed.

The locomotive has a smaller heating-surface per horse-power, a more intense fire being kept up and less economy of fuel being practiced.

Fire-tel'e-graph. See FIRE-ALARM TELEGRAPH.

Fire-tube. (*Steam-engine.*) A furnace-tube through which the flame and heated air pass from the fire-chamber. A *flue*; a *pipe-flue*; or *flame-tube*.

Fire-work. The Chinese led the world in this line in point of priority, and perhaps do yet in quality. Fire-works are said to have been first used in Europe by the Florentines, and are mentioned as a part of the pageant at the marriage of Henry VIII. and Anne Boleyn. They were not common during the reign of Elizabeth, but came into popular use during the reigns of the Stuarts.

Marcus Græcus, in a treatise on pyrotechny (*Liber Ignium*) published about A. D. 825, describes the nature of the composition for making fire-works.

The bearing of fire-works on the invention of fire-arms is referred to in the article on GUNPOWDER (which see). See list under PYROTECHNICS.

Fir'ing. 1. (*Furnace.*) The mode of introducing fuel into the furnace and working it.

Hard-firing; charges in quick succession with frequent stoking.

Heavy-firing; large charges of fuel and frequent stoking. Known also as *close*-firing, *thick*-firing, and *charging*, from the large body of fuel introduced at a time.

Light-firing; moderate and frequent in quantity; coking the charge on the *dead-plate* and then pushing it on to the coals. Also called *open*-firing, as the charge is thinly spread on the grate-bars and the draft is free.

2. (*Glass.*) The process of fixing the colors upon glass. The colors are metallic oxides, ground up with flint glass and borax, and laid by a paint-brush upon the pieces or sheets of *crown-glass*. These are then removed to the kiln, where the colors become fused and unite inseparably with the surface of the glass on which they are laid, the flux enabling the color to melt before the glass plate becomes distorted by the heat. The *crown-glass* being a silicate of potash and lime is much more intractable than a glass into whose composition lead enters. See GLASS-COLORING; GLASS-PAINTING; GLASS-STAINING; ENAMEL.

Fir'ing-i'ron. A farrier's cautery.

Firm'er-chis'el. A chisel, usually thin in proportion to its width. It has a *tang* to enter the handle, in contradistinction to the *framing*-chisel, which has a socket into which the handle fits.

Firmer-chisels are usually eight or twelve in a set of different widths. They are shorter than *paring*-chisels and lighter than *framing*-chisels.

First-coat. (*Plastering.*) The primary coat of coarse-stuff. That of two-coat work is called *laying*, when executed on lath, and *rendering*, when on brick.

The first coat of three-coat work is called *pricking-up* on lath, *roughing-in* on brick.

Digitized by Google

Fish. 1. A strengthening or stiffening bar laid alongside another; as —

The *fish-bar*, which splices the ends of adjacent railroad rails and decreases the tremor or depression at the joint. See FISHING.

One of a pair of bars laid on opposite sides along and tightly lashed to a spar which has been sprung. See SPLICE.

2. A purchase for hauling in on to the gunwale the fluke of an anchor.

Fish-bar. The splice-bar which breaks the joint of two meeting objects, as of railroad rails or scarfed timber. See FISHING.

Fish-beam. A beam with a bulging belly.

Fish-bel'lied. Bellying on the under side, as a beam, a rail, etc.

Fish-block. (*Nautical.*) The block of the fish-tackle for raising the anchor.

Fish-da'vit. (*Shipbuilding.*) A spar or small crane projecting from the bow of a ship for the suspension of the tackle, called the *fish-fall*, used in hauling up the arms of the anchor in getting it aboard. The fish-davit is such a distance abaft the *cat-head* as the length of the anchor may require, and is used to lift the fluke of the anchor to the bill-board; a roller keeps the fluke from bruising the vessel's side.

In preparing for *letting go* the anchor, it is suspended by its throat from the *fish-davit* by a chain or rope called the *shank-painter*, which is cast loose simultaneously with the *cat-head stopper*, the two being secured *on board* by means of movable pins called *tumblers*, which are moved by a lever and disengage the chains or ropes at the same instant.

Fish'er-man's-bend. A sailor's knot, used in bending halyards to a studding-sail yard. Two turns are taken round the spar, the end passed between them and the spar, and half hitched around the standing part.

Fish-fall. (*Nautical.*) The tackle depending from the *fish-davit* and used in hauling up the *arms* of the anchor.

Fish-flake. A structure on which fish are spread to be air and sun dried.

Fish-front. (*Nautical.*) Curved pieces of timber bound upon the outside of a broken spar to stiffen it and make it serviceable.

Fish-garth. A staked or dammed enclosure on the margin of a river to form a fish-preserve.

Fish-gig. A spear with several barbed prongs used in spearing fish. It has usually five prongs, called *grains*.

Fish-globe. A spherical glass vessel forming an aquarium.

"Thence to see my Lady Pen, where my wife and I were shown a fine rarity; of fishes kept in a glass of water, that will live so for ever, and finely marked they are, being foreign." — PEPYS'S *Diary*, 1665.

Fish-glue. Isinglass.

Fish-hook. Fish-hooks are mentioned in the Bible in several places, in connection with brooks, rivers, and the sea.

The first fish-hooks were made of bones or thorns, the latter being indicated by the root of the Hebrew word.

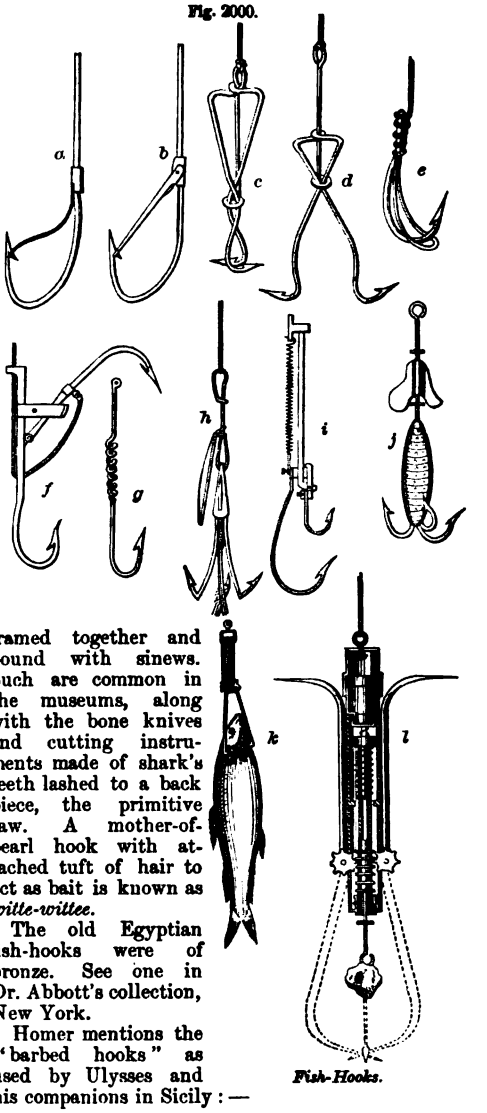
"Canst thou draw out leviathan with a hook" (ancient version, "thorn"), "or his tongue with a cord which thou lettest down?"

"Canst thou put a hook into his nose? or bore his jaw through with a thorn?" — *Job* xli. 1, 2.

The latter verse bears a peculiar significance, referring to the practice of attaching a fish by a hook and cord to a stake, so as to keep it alive in the water. The crocodile, if it be the animal referred to, would require a hook rather larger than those used by the anglers of the Euphrates, with which river we suppose the patriarch of Uz to have been familiar.

The natives of the South Seas in the regions visited by Magellan, Cook, La Perouse, Anson, and others, made fish-hooks of bone, carved or neatly

Fig. 2000.



Fish-Hooks.

framed together and bound with sinews. Such are common in the museums, along with the bone knives and cutting instruments made of shark's teeth lashed to a back piece, the primitive saw. A mother-of-pearl hook with attached tuft of hair to act as bait is known as *witte-wittee*.

The old Egyptian fish-hooks were of bronze. See one in Dr. Abbott's collection, New York.

Homer mentions the "barbed hooks" as used by Ulysses and his companions in Sicily: —

"All fish and birds, and all that come to hand
With barbed hooks."

Odyssey, XII. 332.

Athenæus states (A. D. 220) that "the hooks were not forged in Sicily, but were brought by them in their vessel." — *Athen. Epit.*, B. I. 22.

Of the Grecian fish-hooks, some were bent around and others were straight, with a barb.

In the cut are shown a number of fish-hooks, of which *a b* are two forms of a spring hook in which a mousing-piece engages the barb.

c d are two positions of the same spring hook, one set and the other sprung.

Digitized by Google

e is intended to give the hook a square presentation, and prevent glancing of the hook in striking.

f has a tripping hook which strikes from above, and supplements the primary hook.

g has a spiral-spring shank.

h has a spring hook attached to the snood, which affords the means of attaching a bait or other hook.

i has an additional hook, which is sprung, and thus supplements the primary hook.

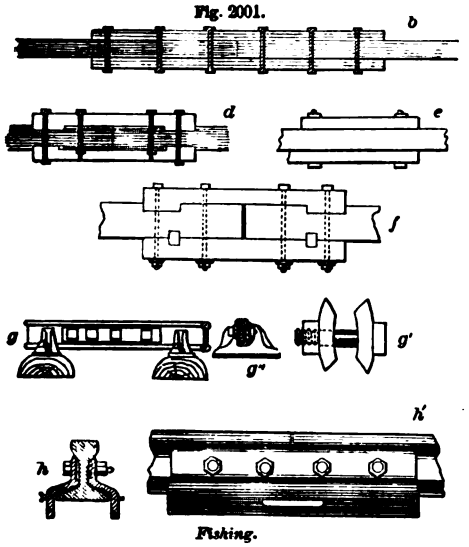
j has spiral vanes, so as to revolve it when drawn through the water in trolling.

k l shows two forms —on different scales — of a spring hook whose claws are thrown down upon the fish which tampers with the bait.

In making the hooks, straight wires of the proper size and length are flattened at one end, and the barb formed by a single blow with a chisel. The point having been sharpened, the proper curve or twist is given to the hook; the soft iron is then case-hardened, to give it the stiffness and elasticity of steel, by immersion in hot animal charcoal. The hooks are subsequently brightened by friction, and tempered. In the hook-making machine, the wire is run from a reel into the machine, and on the other side the fish-hook drops out completed, with the exception that it must be tempered and colored. After the wire reaches a certain point, the requisite length is clipped off. The next operation barbs it; the other end is flattened. It passes around on revolving dies, whose teeth, formed like the notched spikes of a wheel, catch it, and bear it from one operation to the next until it is smoothed and filed, when it passes between rollers that give it the prescribed twist and turn, and it drops into the receiver awaiting it.

Fish'ing. 1. Uniting by clamping between two

Fig. 2001.



Fishing.

short pieces which cover the joint. As a compound beam, *b d e*, Fig. 2001.

At *f* is shown a combination of *fishing-pieces*, *coaks*, and *bolts*; the coaks on the lower surface are substitutes for the *indents* of the surface above.

g g' g'' show one form of clasping plate in several views.

The *fish-plate h h'* for railway-rails has a bend which laps upon the foot of the rail, and a drooping flange; the bent form giving a rigidity which strengthens the rail against deflection. The rail is prevented from opening at the joint, or spreading, as is usual with the ordinary fish-joint, whose strength is only equal to one third that of the rail.

2. (*Nautical.*) Lifting the anchor-fluke on to and over the gunwale.

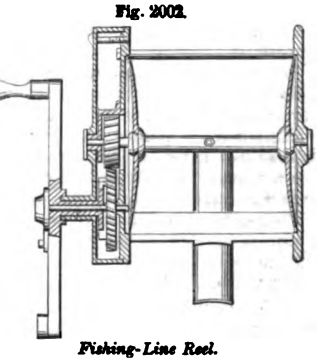
3. Fishing, as an occupation, is perhaps almost coëval with our race. The distinction between netting, trapping, and angling was early understood. "The fishers also shall mourn, and all they that *cast angle* into the *brooks* shall lament, and they that *spread nets upon the waters* shall languish. . . . . They shall be broken. . . . that make *sluices* and *ponds* for fish." (Is. xix. 8, 10.) See also Habakkuk i. 14, 15; Amos iv. 2 (787 B. C.). Oppian wrote a Greek epic on fishes and fishing about A. D. 198. Wynkyn de Worde's "Treatyse of Fysshinge" appeared in 1496, and Walton's "Complete Angler" in 1653.

Fish'ing-line. A flaxen or fine hempen cord for angling.

The Grecian fishing-lines were of horsehair, white nearest to the hook. Horsehair, catgut, and silk are now used for *snoods*.

Fish'ing-line Reel. A little winch, usually attached to a fishing-rod, and upon which the line is wound.

Fig. 2002.



Fishing-Line Reel.

In one case it is furnished with an alarm, so that a sleepy fisher may have notice when a fish runs away with the bait.

Fish'ing-net. See NET.

Fish'ing-rod. Angling for fish was common in ancient Egypt, but they do not appear to have used a float. The line was comparatively short, and the rod in a single length. They used landing-nets. They do not seem to have practiced fly-fishing. Spearing fish, especially with the *bident*, is shown frequently in their sepulchral paintings. The fish-spear was attached to a cord which was wound on a reel.

The hook and fish-spear are mentioned in the Book of Job. Fishing-lines of horsehair are mentioned by Aristotle.

The Grecian fishing-rod was, as now, a reed, — *calamus*. It was not made in jointed sections.

Modern rods are made of bamboo lengths fastened together by telescopic or screw couplings.

Fish'ing-smack. A sloop having a water-chamber in the hold to keep fish alive.

Fish'ing-tube. (*Microscopy.*) An open-ended glass tube for selecting a microscopic object in a fluid. The tube is closed at the upper end by the finger until the lower end is close to the object. The finger being raised the water rushes in, carrying the object with it.

Fish-joint. A plate or pair of plates fastened upon the junction of a couple of meeting portions of a beam or plate. See FISHING.

The fish-joint for connecting railway-rails was first designed by W. B. Adams, England, 1847, and was soon extensively introduced. It consisted of a pair of plates 18 inches long, 3 by ¾ inches, bolted together through the rails by 4 bolts, allowance being

Digitized by Google

made by oval bolt-holes for expansion and contraction of the rails.

The fish-joint with keys instead of bolts was first used (Holley) by Barr of Newcastle, Delaware, in 1843.

In Samuel's fish-joint the bolt passes through a hole in one fish-plate and is tapped into the other. This obviates the nut, which is apt to be in the way of the wheel-flange.

Fish-ket'tle. A long kettle adapted to boil fish of, say, from four to ten pounds' weight, without destroying the symmetry of the fish or cutting it into pieces.

Fish-lad'der. A dam with a series of steps to enable fish to ascend the fall by a succession of leaps. See FISH-WAY.

Fish-plate. A plate used to secure together the ends of adjacent rails, to hold them strictly in line, avoiding lateral deflection or sagging. It usually consists of a plate on each side of the joint, clasping the *web* of the rail, and secured by bolts and nuts. See FISHING.

Fish-pot. An open-mouthed wicker basket containing bait, and sunk in the haunts of fish to catch them.

Fish-skin. The rough skin of the dogfish or shark is used as a rasp.

Shagreen is a leather of fish-skin.

The skins of the porpoise, beluga, and seal are tanned.

Eel-skins are used as *whang*.

Sole and other skins are used in making a kind of isinglass for clarifying liquors.

Fish-slice. A broad-bladed silver knife used for serving fish at table. The trowel-shaped blade enables a portion of fish to be removed from the backbone without breaking it into unsightly fragments.

Fish-spear. A barbed spear for catching fish. A *gig*.

Fish-spears are mentioned by Job and by the Greek writers. They had one, two, or more barbed prongs. Neptune's trident was a fish-spear, tridented or three-toothed.

Fish-tack'le. (*Nautical.*) A purchase to raise the flukes of an anchor to the gunwale, for stowage, after being *catted*. A *fish-fall*.

Fish-tail Burn'er. A gas-burner whose burning jet assumes a two-lobed form, like the tail of a fish.

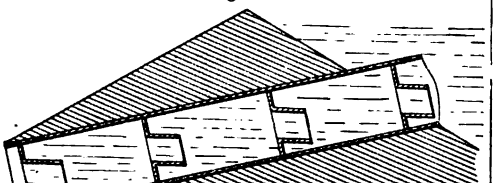
Fish-tail Pro-pel'ler. A single-winged propeller hinged to the stern-post and oscillating like the tail of a fish.

Fish-trap. A box or basket set in a river and having bait slung in a bag to attract fish; it is sprung by hand.

A basket, net, or staked area with a divergent-sided or funnel-shaped opening through which fish pass, and in which they find a difficulty in retracing their course, owing to obstacles or blind sacs.

Fish-way. A device to enable a fish to ascend a fall. It may consist of a series of steps over which the water descends, turning a fall into a cascade, and sometimes known as a fish-ladder; or it may consist of a chute with a sinuous track for diminishing the velocity and assisting the passage of the fish to the level above the dam. In the example, it is an inclined chute having a series of chambers containing comparatively still water, the current being confined to a relatively smaller space.

Fig. 2008.



Fish-Way.

Fis'sure-nee'dle. A spiral needle for catching together the gaping lips of wounds. By revolution, the point is made to pierce the lips alternately, carrying its thread with it. Tiemann's needle for cleft palate is hollow throughout its length, and carries a silver wire which is left in its place when the needle is retracted by backward rotation.

Fig. 2004.

Fissure-Needle.

Fis'tu-ca. A pile-driver. A *monkey*.

Fis'tu-la. A water-pipe, according to Vitruvius, who distinguishes three modes of conveying water: by leaden pipes, by earthen pipes, and by channels of masonry.

Fit-rod. (*Shipwrighting.*) A gage-rod used to try the depth of a bolt-hole in order to determine the length of the bolt required.

Fix. See FIXING.

Fixed Am'mu-ni'tion. A charge of powder and shot inclosed together in a wrapper or case, ready for loading.

Fixed Light. One character of light displayed from a lighthouse. Its beams are constant, differing from those termed *flashing*, *revolving*, and *intermittent*. It is susceptible of variation, as *white* or *colored*, *single* or *double*. See LIGHT; CATOPTRIC-LIGHT.

Fixed Star. (*Pyrotechnics.*) A composition introduced into a rocket-case and emitting fire at five holes, to represent a star. The composition is niter, sulphur, gunpowder-meal, antimony.

Fixed Sun. (*Pyrotechnics.*) A device composed of a certain number of jets of fire distributed circularly like the spokes of a wheel. All the fuses take fire at once through channels charged with quick-matches.

Glories are large suns with several rows of fusees.

Fans are portions of a sun, being sectors of a circle.

The *patte d'oie* is a fan with only three jets.

Fix'ing. 1. (*Photography.*) Of a *negative*; the removal, by a solution of hyposulphite of soda or cyanide of potassium, of the unaffected deposit of iodide and bromide of silver in the collodion film after exposure and development of the picture.

Of a *positive*; the removal of the unaltered chloride of silver from the surface of the photographic paper after exposure under the negative.

2. (*Metallurgy.*) The material used in preparing the hearth of a *puddling* or *boiling furnace* for receiving its charge. A certain amount of ore, cinder, and scrap are banked up around the boshes, the amount and kind varying with the character of the iron and the construction of the furnace. It is called *fettling* in some parts of England, the word *fettle* being provincial English, and substantially the same as our *fix*.

Flack'et. A barrel-shaped bottle.

Flag. 1. A banner indicating nationality, occupation, or intelligence.

Flags of *nationality* are *standards*, *ensigns*, *pennants* (pendants), *jacks*.

Flags of *occupation* indicate service, as *war*, *merchant*, *despatch*, *pilot*, *yacht-squadron*, *liners*, etc.

Flags of intelligence are of various colors and of three shapes: square (*a*), pointed (*b*), burgee (*c*). They are used in various combinations to transmit messages according to a printed or secret code.

Digitized by Google

The *standard* (*military* or *naval*) is a *war* flag.

The *ensign* (*d*, American ; *e*, English) is national. It has the *union* in the upper corner next the staff, the other portion of the flag being denominated the *fly*.

In the English service the ensign with a white fly, a red cross, and the jack in the corner, belongs to war-vessels. Other government vessels carry the *red* ensign (red fly).

The *blue* ensign belongs to the merchant service.

The *pennant* (*f*) is a long strip of bunting, and is used to indicate the commodore's vessel, and formerly, in connection with an ensign, to indicate a government vessel of the nationality to which the ensign belongs.

The *jack* is a flag having the *union* of the ensign without the fly. *g*, American ; *h*, English.

An *anvil* is a little narrow flag or pennon on the end of a lance.

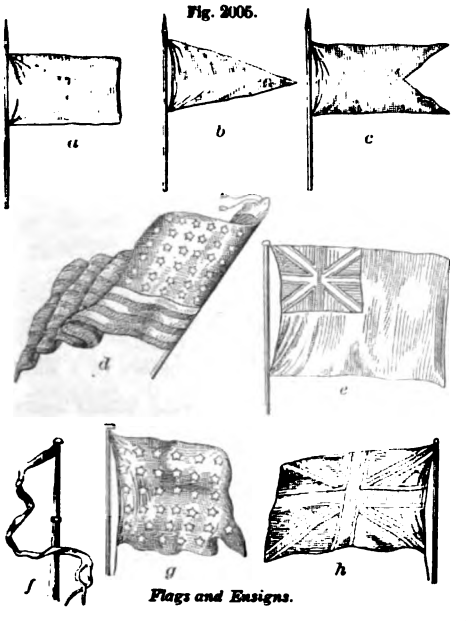
A *banner* is a small flag edged with fringe.

A *bandrol* is a small streamer from a masthead.

A *fanion* is a small flag for a surveying-station ; from the Italian *gonfalone*, a standard.

A *guidon* is a small swallow-tailed flag used in

Fig. 2005.



Flags and Ensigns.

cavalry regiments. One is furnished to each company. See GUIDON.

A *streamer* is a relatively narrow flag or pennon.

Flags with special designs are used on particular occasions, as the flag known as "blue-peter" indicates that the vessel is about to sail. It is a blue flag with a white square in the middle. There are many other signal flags, and some to represent numbers, by which messages may be signaled according to a printed code. See Haswell's "Engineers, etc., Pocket Book," p. 149.

The *hight* of an ensign is the *hoist* or *depth*, and is $\frac{1}{3}$ of its length.

The *length* from the staff to the outer edge is the *fly*.

In the United States service, —

The garrison flag has 20 feet head, 36 feet fly.

The storm-flag has 10 feet head, 20 feet fly.

The regimental flag has 6 feet head, 6 ft. 6 in. fly.

Camp-colors are of bunting, 18 inches square.

The *field* has 13 horizontal stripes of red and white alternately, beginning with red.

The *union* has a blue field in the upper corner, next the *head*, four tenths of the length of the field and seven stripes in depth, with white stars ranged in equidistant horizontal and vertical lines, equal in number to the number of States in the Union. See "Army Regulations," ed. 1863, p. 461.

2. A slab of stratified stone for sidewalks, etc.

3. The uneven end of an uncut tuft of hair in a brush.

Flag'e-o-let. (*Music.*) A wooden musical wind-instrument having a mouthpiece and six principal holes which are stopped by the fingers, as in a flute.

The double flageolet is said to have been invented by Bainbridge, and upon it duets may be played. It is mentioned by Pepys.

"To Drumbleby's, the pipe-maker, there to advise about the making of a flageolet to go low and soft ; and he shew me a way which do do, and also a fashion of having two pipes of the same note fastened together, so as I can play on one, and then echo it on the other, which is mighty pretty." — PEPYS'S *Diary*, 1668.

"I took my flageolette, and played upon the leads in the garden, where Sir W. Pen come out in his shirt into his leads, and there we staid talking and singing and drinking greater draughts of claret, and eating botargo and bread and butter, till 12 at night, it being moonshine, and so to bed, being very near fuddled." — PEPYS'S *Diary*, 1661. (Botargo is a sausage made of eggs and the blood of the sea-mullet.)

Flag'ging-i'ron. (*Coopering.*) A prying-rod with a double-hooked head, used in flagging casks.

Flag'on. A pitcher with a narrow mouth to hold a beverage, ale or wine.

Notably it is of metal, and used to contain the wine of the communion-service, which is poured from thence into the chalice and drunk therefrom.

Flag-stone. A sandstone which cleaves into flat slabs suitable for paving.

Flail. 1. (*Husbandry.*) A wooden instrument for threshing small grain by hand.

"The fitches are beaten with a staff, and the cummin with a rod." — *Isaiah.*

It was used among the Hebrews for grain which would not bear the tramping or the grinding action of the sled or cart.

The flail consists of the *hand-staff* and the *souple*, or *swiple*, which are joined by a piece of whang or eelskin to a swivel called the *hooding*.

The images of the Egyptian Osiris are represented

Fig. 2006.

Japanese Thrashers.

with two instruments, usually called the *crook* and *flagellum*. We are much disposed, however, to consider them a *sickle* and *flail*, and the association on the same figure of the plow and harrow renders the

Digitized by Google

supposition probable. The crook was not held in as much honor as the sickle, nor the tender of animals as the cultivator of the land. A weapon like a flail was used in war, but Osiris was eminently peaceful and useful, and his emblems had the same character.

The flail is the ordinary means of thrashing in Japan. It differs in no essential respect from that of other countries. The illustration, from a native painting, shows that both sexes engage in the work.

2. An ancient weapon used in war. It was a club swinging from the end of a long handle, like the *morning-stars* of the London train-bands, three centuries since.

A war-club studded with *iron* spikes and mounted like a flail was found at Sakkarah, and is in the Abbott Museum of Egyptian Antiquities in New York.

Flake. 1. A platform of slats, wands, or hurdles, on which fish or fruit is placed to dry. A *fish-flake.*

2. A stage suspended over the side of a ship for the convenience of the painters or calkers.

Flame-bridge. A wall rising from the floor of a furnace to cause the flame to impinge upon the bottom of the boiler.

Flame-en'gine. An early name for the gas-engine, in which the piston is moved by the expansion due to the sudden combustion of a body of gas in the cylinder. See GAS-ENGINE.

Flang. A two-pointed miner's pick.

Flange. (*Machinery.*) A projecting rib or rim for strength, as a guide, or for attachment to another object.

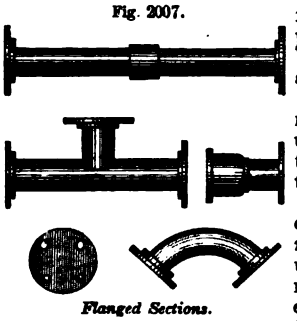
1. A strengthening rib, as in the flange of a fish-bellied rail, or girder.

2. A guide-flange, as in the rib of a car-wheel projecting beyond the tread.

3. A fastening flange, as on the end of pipe, steam-cylinder, etc.

Flange-joint. A joint — such as that of pipes — where the connecting pieces have perforated flanges by which the parts are bolted together.

Fig. 2007.



Flanged Sections.

Flange-rail. A rail having a bent-up flange to keep the wheel on the track.

Flang'ing-ma-chine'. (*Sheet-metal.*) A machine usually having two rollers so constructed and arranged as to bend over the edge of a piece of tin-plate which is passed between them. The modes of bending are known as *bending, burring, seaming, flanging,* etc.

In the example, the outer circumferential corner of the lower disk is turned out rectangularly, and the other disk has a peripheral flange, which enters the groove and forms an out-turned flange around the edge of the cylinder. See DOUBLE-SEAMING MACHINE.

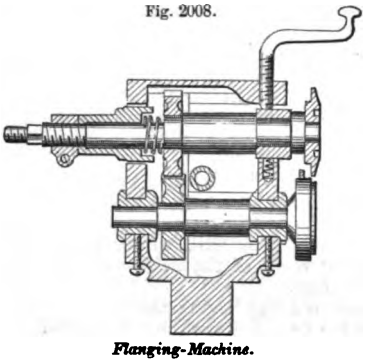
Flank. 1. (*Gearing.*) The acting surface of a cog, *within* the pitch-line. The outer portion is the *face.*

2. (*Architecture.*) The *haunch* of an arch; the shoulder between the *crown* and the *springing.*

3. The thin portion of a skin of leather; that which previously covered the flank of the animal.

4. (*Fortification.*) That portion of a bastion

Fig. 2008.



Flanging-Machine.

which reaches from the *face* to the *curtain.* The *flank* of one *bastion* commands the *ditch* before the *curtain* and the *face* of the opposite *bastion.* See BASTION.

5. The return side of any body, as of a house, a wall, an ashlar in position, etc.

Flan'nel. (*Fabric.*) A soft, open woolen stuff, of which there are many kinds, twilled or plain and undressed, milled, gauze, colored, and checked. Also made for specific purposes, as house, horse, printer's blankets.

Flan'ning. (*Building.*) The internal flare of a window jamb. The *embrasure.*

Or of a fireplace. *Coving.*

Flap. A hinged leaf of a table or shutter.

An inside shutter has several pieces, the principal one of which is the *front shutter;* the one which folds into and is concealed in the *boxing* is the *back-flap.*

Flap-tile. A tile with a bent-up portion to turn a corner or catch a drip.

Flap-valve. A valve which opens and shuts upon one hinged side. A *clack-valve.*

The common pump-valve consists of a disk of leather opening upward when the pump-rod descends, and has a leaden or brass weight attached to it.

Flar'ing. Overhanging, as of the bows of a ship, the top side forward.

Increasing in diameter upward, as of an upwardly expanding pan. *Funnel-shaped, conical, trumpet-mouthed.*

Flash'er. (*Steam.*) A form of steam-boiler in which small bodies of water are injected into a heated boiler and flashed into steam, sufficient being injected at each time for one stroke. See INSTANTANEOUS-GENERATOR.

Flash'ing. 1. (*Hydraulic Engineering.*) Concentrating a fall of water at one point, so as to increase the depth to allow the passage of a boat from one level to another, as at *a.* The river having a *dam* across it and a sluice at one point, the sluice-gate is opened, and during the temporary increase of depth in the sluice-way the boat is drawn through.

It is a very ancient device (see SLUICE), and is still used in many countries with boats of moderate size.

A memorable case of flashing is that when Lieutenant-Colonel Bailey rescued the fleet of gunboats on Red River after the defeat of the Union army under General Banks. The gunboats were *flashed* over the falls at Alexandria by means of a wing-dam made of log cribs filled in with stone.

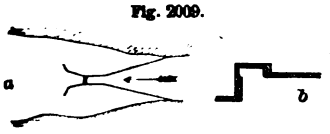
2. (*Plumbing.*) *a.* A lap-joint (*b*) used in sheet-metal roofing, where the edges of the sheets meet on a projecting ridge.

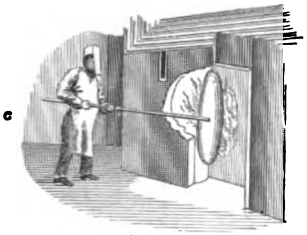
Digitized by Google

b. A strip of lead leading the drip of a wall into a gutter.

Step-flashings are those situated at the junction of the sloping side of a roof and a wall. They are turned in at each course of bricks and stepped down as the roof descends.

Fig. 2009.





Flashing.

3. (*Glass-making.*) *a.* A reheating at a furnace aperture (*c*) in connection with a rotary movement, causing the opening in the flatted sphere of glass to enlarge and eventually to disappear entirely as the table of glass assumes a flat shape.

The flashing heat is also applied to smooth the sheared edges of a goblet or other article, or to reheat an article during manufacture to restore its plastic condition.

b. A mode of covering transparent white glass with a film of colored glass, in order to give the appearance of color to the whole ware. In some cases, the ruby coating is ground away in an ornamental pattern, so that the glass is party-colored. The colored glass is prepared with a composition called SCHMELZE (which see).

Flash'ing-fur'nace. One at which a globe of crown-glass is reheated, to allow it to spring open flatly as it is whirled. See FLASHING.

Flash'ing-light. One character of light as exhibited from lighthouses. It is produced by the revolution of a frame with eight sides, having reflectors arranged with their faces in one vertical plane and their axes on a line inclined to the perpendicular. The rate of revolution is such as to show a flash of light every five seconds, alternating with periods of dimness.

This light is one of the modes of varying the appearance, so that a mariner may be able to distinguish one light from another when coming near land on a coast where the number of lights is considerable; as, for instance, the three kinds on Cape Henry and Cape Charles, at the mouth of Chesapeake Bay, and at Hog Island, on the coast of Northampton County, Virginia, about thirty miles north of Cape Charles.

Lights are distinguished as —

Fixed.	Flashing.
Revolving.	Colored.
Intermittent.	Double.

These are variously combined, as: *revolving white; revolving red and white; revolving red and two whites; double fixed; double revolving*, etc., etc. See LIGHT; LIGHTHOUSE. See "Lighthouses, their Construction and Illumination," by Allan Stevenson; Weale's Series, No. 47.

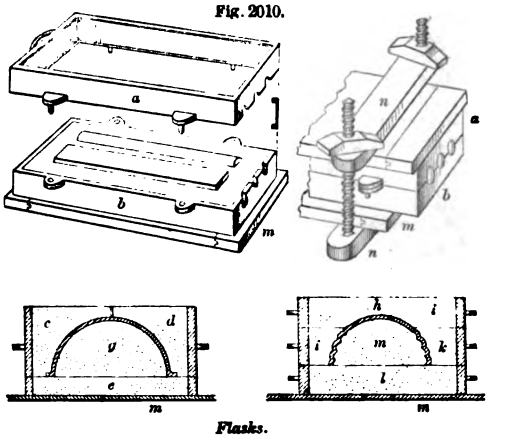
Flash-pipe. A mode of lighting gas by means of a supplementary pipe pierced with numerous small holes throughout its length. The *flash*-pipe reaches from the burner to a position within reach of a person, and is provided with a stop-cock. The cock being turned, gas issues from each orifice. One jet being lit, the flame flashes along the whole length of the pipe, and communicates flame to the jet. The stop-cock is then closed, and the row of small jets is extinguished. Substitutes for the *flash-pipe* are found in the various modes of *lighting gas by electricity* (which see).

Flash-wheel. A water-raising wheel having arms radial or nearly so to its axle, and revolving in a *chase* or curved water-way by which the water passes from the lower to the higher level as the wheel rotates. See SCOOP-WHEEL. See also HYDRAULIC DEVICES.

Flask. 1. (*Founding.*) A frame or box which holds a portion of the mold for casting. If the mold be contained in two pieces, they constitute a *two-part* flask. The upper part contains the *cope* (*a*), the lower part the *drag* (*b*).

In hollow-ware, kettles, etc., the cope consists of two parts *c d*, which divide laterally, and the drag *e*

Fig. 2010.



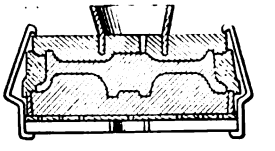
Flasks.

has one part and holds the *core*, or *nowel g*, which is the mold of the interior. This requires a three-part flask.

An example of a four-part flask is one in which the *cope* or casing is in three pieces; one upper piece *h* which is lifted off, and two side pieces *i k* which are removable laterally. The *core* or *nowel m* resting upon the fourth part *l*, the drag. The *drag l* rests upon a bottom board *m*, and has ears at the sides into which the pins of the cope enter, so as to preserve the parts in relative lateral position. When the object is molded and the pattern withdrawn, the *parts* of the flask are secured between top and bottom boards by means of the clamps *n*. See MOLD.

Fig. 2011 shows a car-wheel in a mold with its upper and lower parts and a circular ring which forms and at the same time chills the tread.

Fig. 2011.



Car-Wheel Mold.

Fig. 2012 shows a two-part flask with the mode of securing exact correspondence of the parts by locking hooks and keepers.

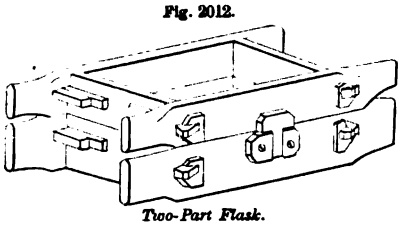
2. A leathern or metallic case for holding gunpowder or shot.

3. (*Glass.*) *a.* A kind of bottle for oil, liquor, or quicksilver. The latter is of iron.

b. A vessel used in a laboratory for sublimation or for digesting in a sand-bath.

Digitized by Google

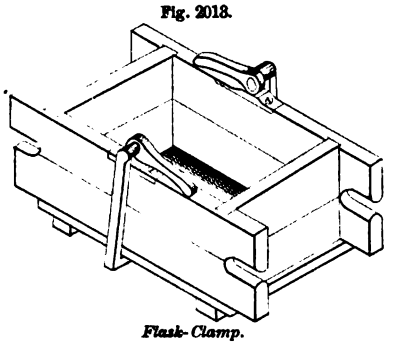
Fig. 2012.



Two-Part Flask.

Flask-clamp. A binding device for securely holding together the parts of a flask. In the example it is a hooked bar and a lever cam.

Fig. 2013.



Flask-Clamp.

Flask'et. A long shallow basket with two handles.

Flat. 1. A Western river-boat or barge for carrying produce, coal, or merchandise.

2. A piece of bone for a button-blank.

3. A surface of size over gilding.

4. A story in a dwelling.

5. A platform railway car.

6. (*Carding.*) A strip of wood clothed with bent teeth, and placed above the large cylinder of a carding-machine.

The clothing is known as the *flat top-cards*, in contradistinction to the cards which clothe the *drum*, *licker-in*, *card-rollers*, *teazer*, and *doffer*, whose surfaces are curved.

7. (*Shipbuilding.*) *a.* A flat part in a curve; as a timber which has no curve, as the floor-timbers of the *dead-flat* amidships.

b. One of a number of ship's frames of equal size, and forming a straight middle body.

Flat'band. A plain, square impost.

Flat-boat. A barge for transporting produce on the Western rivers. A *flat*; an *ark*.

Flat-cap. A size of writing-paper usually 14 × 17 inches.

Flat Chis'el. A sculptor's chisel for smoothing surfaces.

Flat File. A file wider than its thickness and of rectangular section. When bellied, it is known as a *taper* file; when the size is maintained from end to end, it is known as a *parallel* file.

Flat Ham'mer. The hammer first used by the gold-beater in swaging out a pile of *quartiers*, or pieces of gold ribbon, 1 × 1½ inches square. These are placed 24 in a pile and beaten till they are two inches square. They are then packaged with interleaves of vellum and beaten by other hammers, known as the *commencing*, *spreading*, and *finishing* hammers.

Flat-head Nail. A forged nail with a round, flat head and a light, rounded, pointed body.

Flat-i'ron. An iron with a flat face, used for smoothing clothes. A *sad*-iron. See SMOOTHING-IRON.

Flat-i'ron Heat'er. A stove specially adapted for heating smoothing-irons. A *laundry-stove*.

Flat-lead. Sheet-lead.

Flat-nail. A small, sharp-pointed wrought nail, with a flat, thin head, larger than a *tack*.

Flat-pa'per. That which has not been folded.

Flat-press. A press used in the india-rubber business for flattening together a number of piles of folded cloth while they are vulcanized and blended together by a steam heat of say 280° F.

Flat-rail. A railroad rail consisting of a simple flat bar, spiked to a longitudinal sleeper. Tramways of wood were laid down by Beaumont at Newcastle, in 1602. They were protected by flat straps of iron in 1738, at Whitehaven. Flat cast-iron plates were laid at Coalbrookdale in 1767. The angular cast-iron rail was used in 1776. Edge rails of cast-iron in 1789. Rolled rails in 1820. See RAIL.

Flat-rope. A rope made by plaiting yarns together instead of twisting. *Gasket*; *sennit*.

Some flat ropes, for mining-shafts, are made by sewing together a number of ropes, making a wide, flat band.

Flat-rope Pul'ley. A pulley having a true cylindrical surface and two rising flanges, to keep the band from running off. See PULLEY.

Flat'ten-ing-fur'nace. A furnace into which cylinder glass split longitudinally is placed to flatten out by heat. A *spreading-oven*. See FLATTING-FURNACE.

Flat'ter. 1. A hammer with a very broad face, used by smiths in flat-facing work.

2. (*Wire-drawing.*) A draw-plate with a flat orifice, to draw flat strips, such as watch-springs, skirt-wire, etc.

Flat'ting. 1. (*Painting.*) *a.* A style of inside house-painting in which the colors, prepared with oil of turpentine only, are dead, without luster.

b. A covering of size over gilding.

2. A rolling of metal into plates.

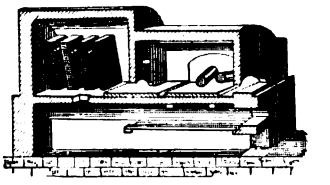
3. (*Glass-making.*) The operation of opening out a split cylinder of glass so as to make it flat. This is performed in a FLATTING-FURNACE (which see), and is assisted by a tool having an iron handle and a wooden cross-piece at the end.

The plate on which it is flatted is of devitrified glass, fire-proof clay, sandstone, or other material which will resist heat and maintain the essential perfectly smooth surface.

It is known as the *spreading-plate*, *flatting-plate*, *flatting-stone*, or *flatting-hearth*.

Flat'ting-fur'nace. One in which a split cylinder of glass is opened out. See FLATTING.

Fig. 2014.



Flatting-Furnace.

William Coffan, of Hammonton, New Jersey, patented a machine for flattening cylinder glass, October 1, 1830, which was intended to prevent injury to the glass while cooling by shifting the stone on which it was flattened from the flattening to the cooling oven.

Flat'ting-mill. 1. A rolling-mill producing sheet-metal.

Digitized by Google

In the Mint; the rolling-mill for producing the ribbon from which the planchets are punched.

The first flatting-mill in England was erected at Sheen, near Richmond, by a Dutchman, 1663.

2. A mill having a pair of hard, polished steel rolls, through which grains of metal are passed to be flatted, for ornamental purposes. The produce is known as *metallic dust*.

Flat-tool. A turning-chisel which cuts on both sides and on the end, which is square. It is used as a bottoming-tool for boxes.

Flaw. 1. (*Weaving.*) A *bore*, *tangle*, or *skip*.

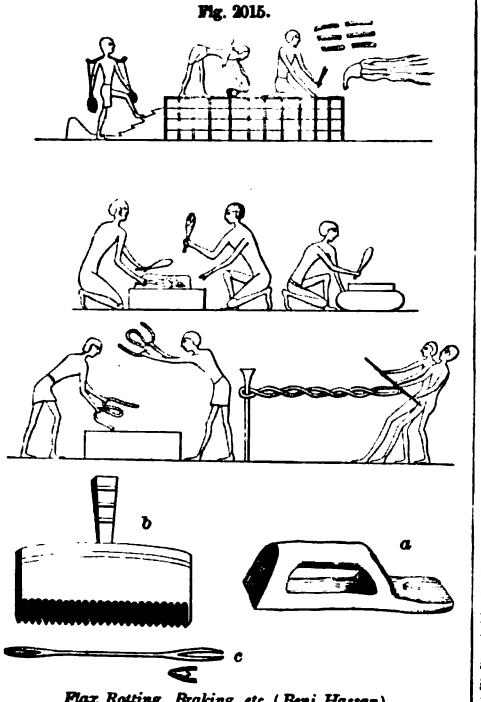
2. (*Metal.*) In casting or forging; a fault, as where the parts of the metal are not fairly joined.

Flaw-piece. (*Wood.*) A slab, from the outside of the log.

Flax. The first mention of flax in history is perhaps that in the account of the hail-storm in Lower Egypt, Exodus ix. 31: "The flax was bolled." The Hebrew word is rendered *linon* in the Septuagint; *linum* in the Vulgate: with us it is *line* and *linen*. (See LINEN.) Flax was used to the exclusion of wool for priestly garments and cerements. Isaiah refers to the fine linen of Egypt; Herodotus refers to linen shirts as the ordinary dress of the people of the Nile land.

The manipulations of flax to render it fit for use are shown at Beni Hassan in Egypt, about 1500

Fig. 2015.



Flax Rotting, Braking, etc. (*Beni Hassan*).

B. C. In the illustration the men on the left are carrying water in jars to pour on the flax, which is placed in an elevated cistern, partitioned off into cells. Another man removes the rotted flax and lays it out to dry, as represented by the six bunches. Another bunch is shown in a loose condition, probably a handful in condition for the next operation, which is performed by the three kneeling men, who beat upon a stone with a mallet *a*. The flax is thus made into a rough hank, and is then cleaned and opened out more fully by striking it upon a stone. The hank is held in two places, swung in the air, and beaten upon the flat stone. In the next scene the hank is twisted and worked to give it a farther finish.

The description given of the process by Pliny, who wrote about 1500 years afterwards, will nearly apply to the serial picture just described. He says: "The stalks themselves are immersed in water, warmed by the heat of the sun, and are kept down by weights placed upon them; for nothing is lighter than flax. The membrane or rind becoming loose is a sign of their being sufficiently macerated. They are then taken out and repeatedly turned over in the sun until perfectly dried; and afterwards beaten by mallets on stone slabs. That which is nearest to the rind is called *stupa* (tow), inferior to the inner fibers and fit only for the wicks of lamps. It is combed out with iron hooks until all the rind is removed. When made into yarn it is polished by striking it frequently on a hard stone, moistened with water; and when woven into cloth it is again beaten with clubs, being always improved in proportion as it is beaten."

Answering to the "iron hooks" described by Pliny, and to our *hackle*, were the combs like that shown in the cut *b*; two of which were found at Thebes, with some flax-tow attached, and are now in the Berlin Museum. One of them has 29 and the other one 46 teeth. *c* is a netting-needle from the same place.

Flax was exported from Egypt to Gaul as late as the Christian era, and was ordered to be grown in England by statute of Henry VIII., 1533. A braking and scutching machine was run by water-power in Scotland in 1750.

To prepare flax for manufacture, after the removal of the seeds, the *hare* (useful, fibrous portion) is separated from the *boon* (the refuse portions of the stalk). For this purpose the uniting gluten must be dissolved and removed. This is effected by rotting, either in ponds or by exposure to dew. In either case a fermentation ensues which renders the gluten soluble in water. Caustic alkali has the same effect on gluten, and forms the basis of many modern processes whereby woody fiber is rendered suitable for spinning or for paper pulp. The next process is to *break* and *scutch* the flax to detach and remove the rind and cellulose matter, and prepare the fiber for *hackling* and subsequent operations.

In one large establishment in Leeds, England, the series of machines is as follows: —

The seed is removed by rollers which act upon the bolls. Then come the *flax-braking machines;* these have fluted or grooved rollers, between which the flax stem is made to pass, so that the woody portion becomes thoroughly broken without cutting the fiber. Next come the *flax-scutching* machines, in which revolving blades or arms beat out the woody fragments, and the fibers are to a certain degree separated. After this the *flax-hackling* machines give the flax a thorough combing, by means of long rows of teeth or spikes; the fibers are combed out straight and tolerably clean; and the tow or short fibers are removed, to be used for other purposes. The hackled flax is then in a state to be acted on by the various machines which bring it into the state of yarn for weaving; these machines are of three kinds, according as tow, long flax, or cut flax is to be acted upon. The *tow-carding* and the *tow-roving* machines serve for the first kind; the *flax-spreading*, *flax-carding*, and *flax-roving* machines for the second; and the flax-cutting machine, followed by those for carding and roving, for the third. The

Digitized by Google

spinning-machine follows all these; and it differs from cotton-spinning machines chiefly in having a provision for wetting the flax either with cold or hot water; there is still a little gum or mucilage among the fibers, and this becomes more manageable in the machine when moistened.

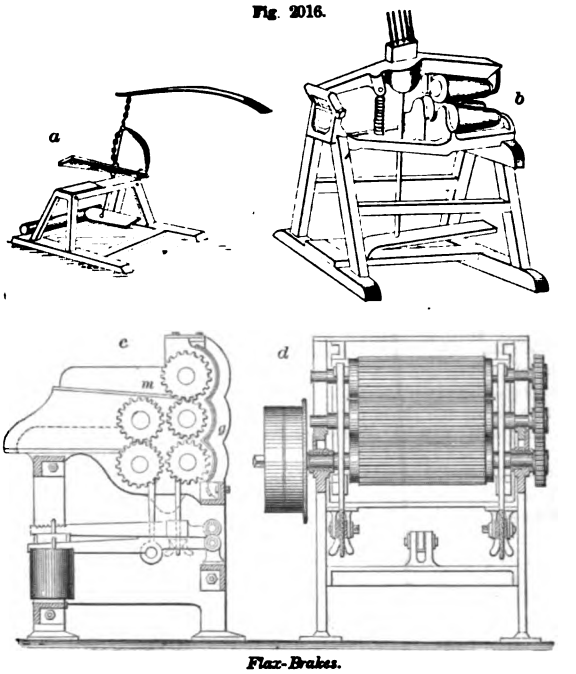
A Swedish method of treating flax is by boiling in sea-water with the addition of birch-ashes and quicklime. It is then rinsed in sea-water; soaped, rubbed, bleached in the air, being turned and watered every day. The washing, soaping, and bleaching are repeated. The flax is beaten, dried, and then carded and spun like cotton.

For list of appliances in the treatment and manufacture of flax, see COTTON, FLAX, WOOL, ETC., APPLIANCES.

Flax-brake. 1. A machine for removing the woody and cellular portion of flax from the fibrous. The hemp-brake is substantially similar in its construction and identical in its purpose.

The first mode adopted may be assumed to have been beating the rotted flax with a stick on a flat stone, alternating with rubbing by the hands. A sword of wood which descends upon the stalks laid over a pair of slats set edgeways, a farther improvement, which is shown at *a*, in which the sword is drawn down by a treadle and lifted by a spring-pole. To this succeeds a pivoted jaw with a series of parallel longitudinal serrations descending upon a similarly provided jaw on the bench.

Fig. 2016.



Flax-Brakes.

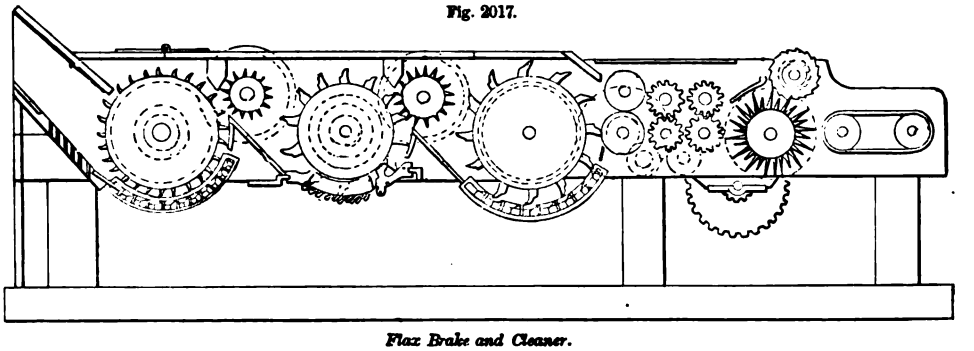
b is a machine having a system of three rollers, the upper one of which is attached to a lever which draws it down upon the other two by means of a treadle, clamping the flax, which is then drawn through by hand, breaking the *shives* from the *hare*. This is repeated as often as may be neccessary, raising the head each time for the insertion of the flax. This part of the process being completed, the flax is reduced to a fine straight fiber by means of the hackle above the lever.

The machine shown in side and end elevations *c d* has cast-iron fluted rollers, five in number, arranged in two vertical series, the front one of two rollers and the back one of three.

The flax straw fed into the machine at *m* passes between the top and middle rollers of the back series, and is directed downward by the back plate *g*, so as to pass between the middle and bottom rollers of the same series and then through the two rollers of the front series. The rollers are all driven and their ends have plain parts truly turned so that the flutes of one roller work into the spaces of the next adjoining roller, and leave a space for the flax straw to pass through. The rollers are weighted, and the pressure can be regulated as required.

Fig. 2017 shows a machine for consecutive rotary

Fig. 2017.



Flax Brake and Cleaner.

treatment. The devices are for drawing, straightening, and extending a layer of tangled flax so as to reduce it to a thin, even sheet of parallel stalks ready for the breaker, scutcher, beater, and picker, to which it is passed directly and continuously.

The drawing-cylinder has alternately long and short teeth, and the roller above has indentations in the peripheries of its annular rings for impaling the stalks. The scutching and cleaning cylinders have flat, narrow, deep teeth, with inclined front edges, slightly hooked at the ends. The teeth of the picking-cylinder are made of pointed round wire, and are inclined backward at their bases, their points curving forward. The concave of the cleaning-cylinder is formed of parallel curved grate-bars, between which pass the teeth of the cylinder. The fiber is

Digitized by Google

forwarded between each cylinder by chute and toothed shell roller.

2. A machine for shortening flax staple to adapt it to be worked by a given class of machines.

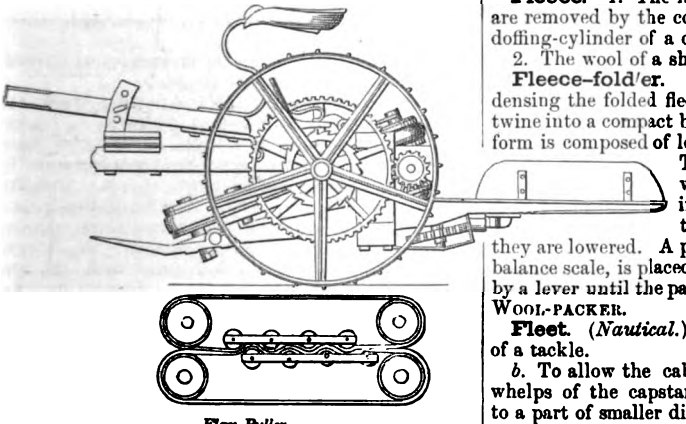
Flax-cot'ton. A process was invented by Chevalier Claussen for cottonizing flax, to render it suitable for manufacture, the objects being to expedite the processes of separating the fiber from the cellular and glutinous matters, and then reducing the fiber to a staple which can be readily treated by machinery. The flax-straw is boiled for four hours in a solution of caustic alkali in a stone vessel, by which the extraneous matters are loosened; it is then placed for two hours in a bath slightly acidulated with sulphuric acid. It is then dried and scutched to remove the cellulose. The cottonizing is performed by steeping the fiber in a bath of dilute bicarbonate of soda, and subsequently in an acidulated liquid. The action of the acid and alkali within the flax fiber generates carbonic-acid gas, and has the effect of bursting apart the fibers, which assume a cottony appearance. It is then bleached and spun, either mixed or otherwise.

In the first volume of the "Transactions of the Society of Arts" is a paper detailing the experience of Lady Moira, about 1770, in attempting to introduce flax cotton. She states that tow and refuse flax of all kinds, boiled with an alkaline solution, and afterwards soured, is converted into a sort of cotton which takes dye better than flax. Her comments are really noteworthy, and illustrate the oft-told tale of the difficulties which inventors and discoverers have to struggle against in the preconceived opinions of others.

Flax-cut'ting Ma-chine'. Flax is sometimes cut before hackling in order to enable its separation according to quality. The machine for this purpose has a circular saw which partly cuts and partly tears its way through the bunch of flax which is presented to it by pairs of parallel rollers on each side of the saw.

Flax-pull'er. A machine for pulling flax-plants

Fig. 2018.



Flax-Puller.

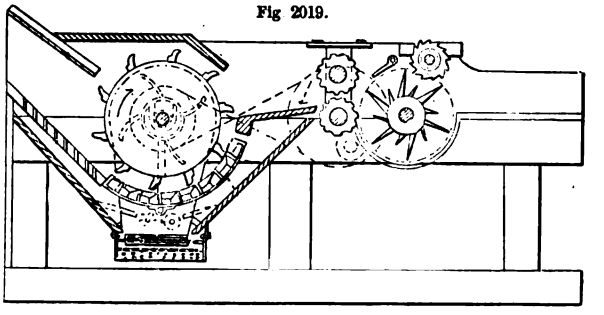
in the field. In the example, the flax passes between a series of dividing fingers, and is seized by the endless rubber belts which are so inclined from the horizontal as to draw the flax from the ground and deposit it on the platform.

Flax-scutcher. See SCUTCHER.

Flax-seed Mill. One for grinding flax-seed for the more ready abstraction of the oil, generally known as linseed (*lint*, flax) oil. It is usually a coarse grist-mill, but is sometimes of a portable form and size for farm or plantation use, and adapted for other grain and seeds. See GRINDING-MILL.

Flax-thrasher. One for beating the grain from the bolls of the cured flax-plant. In the example, the tangled flax is impaled by the spiked roller against the indented roller above, while the drawing rollers straighten the stalk and feed it to the thrashing

Fig 2019.



Flax-Thrasher.

cylinder, which removes the bolls: the latter then fall between the crushing rollers, which release the seed to be cleaned by the vibrating winnower beneath.

The difficulty in thrashing flax consists in its tendency to wrap around the shafts and thrashing cylinder.

Fleam. A spring lancet for bleeding horses.

A gum-lancet. The fleam (phlebotom) was used by the Greeks.

Fleam-tooth. Of a saw. One in the form of an isosceles triangle. A *peg-tooth*.

Fleche. (*Fortification.*) An advanced work at the foot of the glacis, consisting of a parapet with faces forming a salient angle, open at the gorge. It has a communication with the covered way cut through the glacis.

Fleece. 1. The fine web of carded fibers which are removed by the comb or doffing-knife from the doffing-cylinder of a carding-machine.

2. The wool of a sheep in an unbroken mat.

Fleece-fold'er. A kind of press used in condensing the folded fleece so that it may be tied by twine into a compact bundle for shipment. The platform is composed of leaves hinged to a central piece. The wool is laid on the leaves, which are then raised and held in position by notched bars until the package is bound, when they are lowered. A plate, connecting with a spring-balance scale, is placed in the central piece and raised by a lever until the package of wool rests upon it. See WOOL-PACKER.

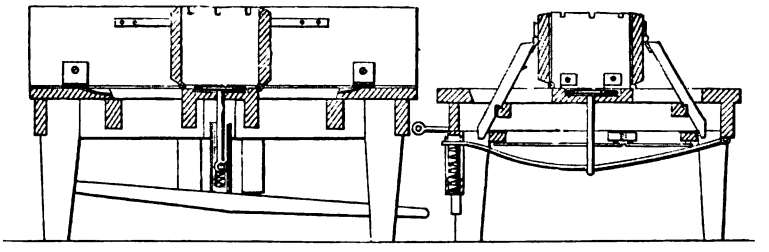
Fleet. (*Nautical.*) *a.* To draw apart the blocks of a tackle.

b. To allow the cable or hawser to slip on the whelps of the capstan or windlass, from the larger to a part of smaller diameter.

Flem'ish-eye. (*Nautical.*) An eye made at the end of a rope, without splicing. The ends of the strands are tapered, passed over oppositely, marled, and sewed with spun-yarn. A *made-eye*, in contradistinction to a *spliced-eye*.

Digitized by Google

Fig. 2020.



Fleece-Folder.

Flem'ish-horse. (*Nautical.*) A foot-rope for the man at the earing in reefing. The *horse* extends below the yard; the *Flemish horse* is the outer portion.

Flesh-brush. A soft brush to be used on the skin to promote circulation and excite the surface secretions.

Flesh-hook. A hook to hang meat.

A hook to handle meat in a pot or caldron.

Flesh'ing. (*Leather-manufacture.*) The operation of removing fat, flesh, and loose membrane from the flesh side of skins and hides. The operation follows that of *unhairing*, and is performed on a beam by a convex knife with a sharp edge.

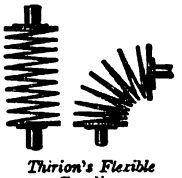
Flesh'ing-knife. A convex knife with a sharp edge used in removing the flesh and fat from the inner surface or *flesh-side* of the hide.

Flews. A sluice for letting waters off irrigated meadows (Scotch).

Flex'i-ble-bind'ing. (*Bookbinding.*) A book sewn on bands raised above the back of the folded sheets, so as to allow them to open more freely. The sewing-thread passes around the bands.

Flex'i-ble-coup'ling. Thirion's flexible coupling is used for conveying power from one shaft to another when they are not in line. It is a spiral steel band attached at its opposite ends to the two shafts to be connected. The diameter of the spiral is larger than that of the shaft, and the attachment is shown as consisting of a cast-iron cap. For a joint of transmission amounting to a right angle, fifteen coils of a spiral will be sufficient. Another form is a cylindrical plug or rod of india-rubber connecting the shafts. See also UNIVERSAL JOINT.

Fig. 2021.



Thirion's Flexible Coupling.

Fli'er. See FLYER.

Flight. 1. (*Carpentry.*) A series of parallel steps proceeding in one direction without turning.

In *dog-legged* stairs, the lower is the *leading* flight, the upper the *returning* flight.

2. The slope or inclination of the arm of a crane or of a cat-head.

3. A spiral wing or vane on a shaft, acting as a propeller or conveyor.

Flight'er. A horizontal vane revolving over the surface of wort in a cooler, to produce a circular current in the liquor.

Flint. A variety of silicious stone used to strike fire; also largely used in making the fine kinds of pottery. Its uses — domestic and for fire-arms — for striking fire are now much abridged among civilized nations. The friction-match and fulminating-powder have superseded the flint and steel.

Flint-glass. This description of glass is made into tumblers and other drinking-vessels, fine table ware and bottles, and various articles of decorative furniture and fittings. It is made of white sand, 52; carbonate of potash, 14; and oxide of lead, 33; alumina, 1; with metallic additions to neutralize color. The articles are made by the agency of the blow-pipe, or ponty, the mold and press, and frequently by a combination of blowing and pressing. The silica for its manufacture was formerly derived from pulverized *flints*, and hence its name. The presence of lead gives it a peculiar property of refracting light, which causes it to be used for lenses, and it forms one of the parts in achromatic compound lenses.

It fuses at a lower temperature than ordinary glass, such as the *crown*, *plate*, or *window* glass. It has also less color, owing to the use of the alkali potash, instead of soda, the latter imparting a greenish tinge to glass.

Flint-glass is softer than some other varieties, and is the kind which is *cut*.

Artificial gems consist of flint-glass, colored in imitation of the natural tints of the gems. See STRASS.

Pure white sand free from oxide of iron is required for flint-glass, as iron imparts a green color.

The Bohemian glass is a silicate of potash and lime, a little of the silicate of alumina being substituted for the oxide of lead. The silica for this glass is obtained by pounding pure white quartz.

Flint-glass work is classed as —

1. Blown.
2. Molded and pressed.
3. Cut and engraved.
4. Reticulated and spun with a variety of colors, incrusted, flashed, enameled of all colors, opalescent, imitation of alabaster, platinized, silvered, etc.
5. Glass mosaic, Millefiori, Aventurine, and Venetian glass weights, etc.
6. Beads, imitation pearls, etc.
7. Glass accessories to lamps, gas-lights, brackets, etc., such as globes, chimneys, drops, bells, reflectors, etc.

Flint-knife. A knife of archæological interest, made from flint chipped to shape.

Flint was very early used as a cutting implement by the nations so fortunate as to possess it. A sort of saw, which passed for a knife, consisted of flakes of flint inserted into wooden handles and secured by bitumen or by lashings of gut or sinews. Obsidian was used in the same way. The South-Sea-Islanders had no flint or obsidian, and used shell, splinters of bamboo, and flakes of tortoise-shell. See KNIFE.

Flint-lock. The old-fashioned lock for fire-arms, in which the cock held a piece of flint and came glancing down upon the steel cap of the pan which contained the priming.

Flint-locks were invented early in the seventeenth century, and gradually superseded the match-lock. Pyrites or marcasite was also used. See GUN-LOCK.

Flint-mill. 1. (*Pottery.*) A mill in which burned flints, having been previously stamped to reduce them below a certain size, are ground to powder for mixing with clay to form *slip* for porcelain.

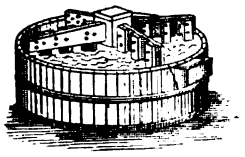
The flint-mill is a strong circular pan ten or twelve

Digitized by Google

feet in diameter, having a bottom of quartz or felspar blocks, and a runner or runners of hard silicious stones, called *chert*, lime in any form being inadmissible, as it forms a flux for the other material which would vitrify in the *seggars* or become blistered by the escape of carbonic acid.

The mill is of the nature of an *arrastra*, as the running stones are blocks driven by depending bars from the arms which project radially from the rotating vertical axis.

Fig. 2022.



Flint-Mill.

The fractured flint is fed into the pan, and water to the depth of eight inches is added. The flint is ground by being levigated between the runners and the bed, and by grinding the particles against each other.

The machine resembles the arrastra of Spain and the Spanish countries of America, excepting that in the arrastra the blocks are dragged around in the bed, being connected by thongs to the revolving arms; and also that the argentiferous slimes are treated with mercury in the arrastra, instead of being merely levigated in water. See ARRASTRA.

The flint-pan is the invention of Brindley, so celebrated for his energetic prosecution of the British canals. Before its introduction the flints were ground dry, and the dust proved very fatal to the work-people.

Mills of similar character, on a smaller scale, are used for grinding felspar, broken porcelain, and other ingredients used in the pottery and porcelain manufacture.

2. (*Mining.*) A mode formerly adopted for lighting mines in which flints studded on the surface of a wheel were made to strike against a steel and give a quick succession of sparks to light the miner at his work. Sparks will not inflame the fire-damp.

Flint-wall. A wall common in some parts of England, made of broken flints set in mortar, and with quoins of masonry. The black surfaces of the broken flints are exposed on the face of the wall.

Flint-ware. (*Pottery.*) A superior kind of earthenware into whose composition ground flint largely enters. See PORCELAIN.

Flisk. A large-toothed comb.

Flitch. (*Carpentry.*) *a.* One of several associated planks which are fastened side by side to form a compound beam, or *built-beam.*

b. A bolt of planks, united by the *stub-shot.*

Float. (*Hydraulic Engineering.*) 1. One of the boards or paddles attached to the radial arms of a paddle-wheel or water-wheel.

2. The hollow, metallic ball of a self-acting faucet, which *floats* upon the water in the cistern or boiler. See BALL-COCK.

3. The quill or cork from which the bait line is suspended, and whose motion indicates the bite of a fish.

4. A plasterer's trowel (*a*), used in spreading or *floating* the plaster on to a wall or other surface.

The *long* float is of such a length as to require two men to use it.

The *hand*-float is that in ordinary use.

The *quirk*-float is used in finishing moldings.

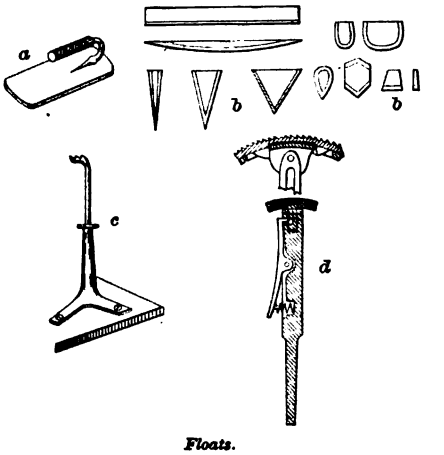
An *angle*-float is shaped to fit the angle formed by the walls of a room.

5. A *single-cut* file, or one in which the teeth are parallel and unbroken by a second row of crossing teeth.

The usual horizontal obliquity of the teeth relatively to the central line of files is 55°, but *single-cut* files are much less inclined, and the teeth of *floats* are sometimes square across the face of the file.

The floats of comb-makers and ivory-carvers are made of various shapes (*b b*), and those of the former

Fig. 2023.



Floats.

are known by specific names, as *graille, found, carlet, topper.* (See COMB.) The teeth have a forward inclination of about 15°, and are made by a file, not a chisel. They are of a lower temper than usual, and are sharpened by a burnisher.

6. The serrated plate (*c d*) used by shoemakers for rasping off the ends of the pegs inside the boot or shoe.

7. (*Tempering.*) A contrivance for affording a copious stream of water to the heated steel surface of an object of large bulk, such as an anvil or die in the process of tempering. The rapid production of steam prevents the constant contact of cold water when the object is merely dipped, as a body of steam intervenes. The dashing stream of water exposes constantly a new body of water to the hot surface, and makes the hardening more complete.

In the English Mint, a powerful jet of water is used in hardening the dies.

8. A coal-cart.

9. A small raft of timber, say 18 feet square and 1 foot deep.

10. A polishing-block used in marble-working. A *runner.*

11. An inflated bag or pillow to sustain a person in the water. A *cork-jacket.* Ormsbee's float is an annular bag placed as a sleeve upon the arm or around the buttocks. It is made of water-proof material, and is inflated when required. See LIFE-PRESERVER.

Float-board. One of the boards of an undershot water-wheel or of a paddle-wheel.

Float-case. (*Hydraulic Engineering.*) A caisson to be attached to a submerged ship or other body, to float it by the expulsion of water and substitution of air in the case.

Float'er. (*Hydraulic Engineering.*) A registering float on a graduated stick to indicate a level attained between periods of observation.

Float'ing. 1. (*Weaving.*) A term applied to a thread which spans a considerable number of threads without intersection. This is an incident to twilling. (See TWILL.) *Diapers*, for instance, are *five-leaf twills;* that is, every warp *floats* under four

Digitized by Google

threads of woof, and is raised and interwoven with the fifth. Also called *flushing*.

2. The second coat of three-coat plastering.

Float'ing-an'chor. (*Nautical.*) A frame of spars and sails dragging overboard, to lessen the drift of a ship to leeward in a gale. A DRAG-ANCHOR (which see).

Float'ing-bat'tery. A vessel strengthened so as to be shot-proof, or as nearly so as possible, and intended for operating in comparatively smooth water, for defending harbors or attacking fortifications.

We are told that a ship of this kind called the "Santa Anna," sheathed with lead, of 1,700 tons burden, carrying 50 guns and having a crew of 300 men, was built at Nice in 1530. She belonged to the Knights of St. John, and was employed by Charles V. against Tunis in 1535.

At the siege of Gibraltar in 1782, by the French and Spanish, ten Spanish war vessels were converted into floating-batteries by strengthening their sides with timber, raw hides, and junk, to a thickness of

Fig. 2024.

Crimean Floating-Battery.

seven feet; they were also fitted with sloping bomb-proof roofs or decks, and are said to have mounted 212 guns, principally 32-pounders, which were considered heavy guns in those days; they were manned with more than 5,600 men, and provided with furnaces for heating shot and arrangements for extinguishing fires. They were constructed by D'Arcon, a French engineer, and were first employed in the attack of September 13, 1782, and sustained the heaviest fire of the British during nearly the whole of that day without apparent injury, but were at last set on fire by hot shot.

In 1813, Robert Fulton submitted a plan to the United States government for the construction of a large floating-battery, which was accordingly built; she was 156 feet in length, 56 feet beam, and 20 feet deep, propelled by a single wheel 16 feet in diameter; her sides were very thick, and she is said to have attained a speed of five miles an hour against the tide.

During the Crimean war the French constructed several floating-batteries, which were sent into the Black Sea, and rendered very efficient service at the capture of Kinburn. The English shortly afterwards commenced building vessels of a similar class, but none of these were completed in time to be of service during that campaign.

Those of the French were of wood, and plated with iron four inches in thickness; they were built very flat, but were to a certain extent sea-going vessels.

The English ones, such as the "Erebus," were constructed almost exclusively of iron, and mounted a very heavy battery, consisting of thirty 8-inch guns.

The Stevens floating-battery is a very sharp screw steamer, designed for great speed, and will be found more fully described under the head of ARMOR-PLATING. See also IRON-CLAD; MONITOR; etc.

Float'ing-bridge. 1. A form of ferry-boat which is guided and impelled by chains which are anchored on each side of the river, and pass over wheels on the sides of the vessel, the wheels being driven by steam-power. Lifting platforms at each end admit vehicles.

2. The *floating-bridge* for canals rests on a *caisson* or *ponton*, and is opened and closed by chains and windlasses. When it is open, it lies in a recess in the side of the canal made to receive it. The ponton is made of sheet-iron, and is designed to act as a girder when the bridge is closed.

Bridges across the Hamoaze, Humber, and Itchin, in England, and the bridge which so long crossed the Susquehanna at Havre de Grace, Maryland, are instances of floating-bridges which might almost as well be called ferry-boats; the distinction is not easy to draw, and is not very important. The train ran on to a high deck and was floated across; the differences of level due to tide were met by a hinged trainway.

Float'ing-clough. A barge with scrapers attached, which is driven by the tide or current, to rake up the silt and sand over which it passes, so that the sediment may be removed by the current.

Float'ing-dam. (*Hydraulic Engineering.*) A caisson used as a gate for a dry-dock.

Float'ing-der'rick. One adapted for river and harbor use, in raising sunken vessels, moving stone for harbor improvements, etc. See DERRICK.

Float'ing-dock. An iron vessel of a rectangular shape, with a rounded bow and a strong caisson gate at the stern. The vessel has a double skin, with a large intervening space. Into the inner basin a ship is floated while the dock is partially submerged; the caisson being closed, the water in the dock and in the space intervening between the two skins is pumped out, so that the interior may be dry, to allow work on the vessel, and the jacket may have sufficient flotative power to carry its load.

The estimated proportions of the inner and outer skin are: the latter should be one third broader and deeper than the former. The intervening space is divided by bulk-heads.

The weight or unloaded displacement is estimated at $\frac{4}{10}$ to $\frac{6}{10}$ of its load displacement, giving from $\frac{4}{11}$ to $\frac{4}{10}$ for its lading.

The largest vessel — for such it is — of this class is the "Bermuda," built in England and navigated to the Bermudas, being towed by two war vessels by way of Madeira, where there was a relay of tugs. This dock cost $1,250,000, and is represented on the opposite page. It has the following dimensions: extreme length, 381 feet; width inside, 83 feet 9 inches; width over all, 123 feet 9 inches; depth, 74 feet 5 inches. The weight of the dock is 8,350 tons.

The dock is U-shaped, and the section throughout is similar. It is built with two skins fore and aft, at a distance of 20 feet apart. The space between

Digitized by Google

the skins is divided by a water-tight bulk-head, running with the middle line the entire length of the dock, each half being divided into three chambers by similar bulk-heads. The three chambers are respectively named "load," "balance," and "air" compartments. The first-named chamber is pumped full in eight hours when a ship is about to be docked, and the dock is thus sunk below the level of the horizontal bulk-heads which divide the other two chambers. Water sufficient to sink the structure low enough to admit a vessel entering is forced into the balance chambers by means of valves in the external skin. The vessel having floated in, the next operation is to place and secure the end caissons, which act as gates, and eject the water from the "load" chamber. Then the dock with the vessel in it rises, the water in the dock being allowed to decrease by opening the sluices in the caissons. The dock is trimmed by letting the water out of the "balance" chamber into the structure itself. The inside of the dock is cleared of water by valves in the skin, and it is left to dry. When it becomes necessary to undock the vessel, the valves in the external skins of the "balance" chamber are opened in order to fill them, and the culverts in the caissons are also opened, and the dock sunk to a given depth. From keel to gunwale nine main water-tight ribs extend, farther dividing the distance between the two skins into eight compartments. Thus there are altogether forty-eight water-tight divisions. Frames made of strong plates and angle-iron strengthen the skins between the main ribs. Four steam-engines and pumps on each side—each pump has two suctions, emptying a division of an "air" chamber—are fitted to the dock, and these also fill a division of the "load" chamber. When it becomes necessary to clean, paint, or repair the bottom of the dock, it is careened by the weight of water in the load chambers of one side, and the middle line is raised about five feet out of the water.

The "Royal Alfred," bearing the flag of the admiral on the station, and weighing 6,000 tons, was lifted by this dock, her keel resting on a central line of blocks arranged on the floor of the dock, the ship being shored up with timbers all round the top-sides.

A similar dock was sent in sections to Carthagena, and lifted several vessels of from 3,800 to 5,600 tons, in one case (the "Numancia") supporting the vessel eighty days.

Float'ing-har'bor. A breakwater of cages or booms, anchored and fastened together, and used as a protection to ships riding at anchor to leeward.

Float'ing-light. 1. A light exhibited at the mast-head of a vessel moored on a spit or shoal where no adequate foundation exists for a permanent structure. The *screw-pile*, in affording a new means of founding structures, has enabled light-houses to supersede floating-lights in numerous cases. A *light-ship*.

2. A life-preserving buoy with a light to attract the man overboard, and to direct the crew of a boat coming to his rescue.

Float'ing-plate. (*Stereotyping.*) A flat cast-iron plate placed at the bottom of a square cast-iron tray in which a stereotype is cast. The plaster mold is laid, face down, on the *floating-plate*, and the two are placed in the heated *dipping-pan*, the cover of which is screwed on. The *dipping-pan* is plunged in an iron pot containing the molten alloy, which runs in at the gates and floats the plate and mold; the latter has notches at its edges, which allow the metal to penetrate between it and the plate. The result is a casting with a flat back, and a face with cameo impression resembling the original type.

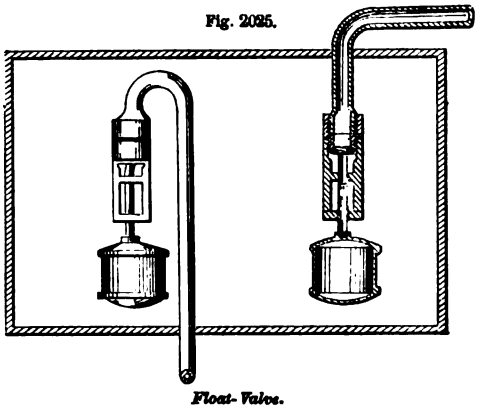
Float'ing-safe. A buoy-shaped receptacle for papers, letters, and valuables, to be cast overboard in case of foundering or wreck.

Float'ing-screed. (*Plastering.*) A strip of plastering first laid on to serve as a guide for the thickness of the coat.

Float-stone. (*Bricklaying.*) A rubber used by bricklayers for smoothing compass-bricks for curved work, such as the cylindrical backs and spherical heads of niches. It takes out the axe-marks acquired in roughly dressing to shape.

Float-valve. A valve actuated by a float so as to open or close the port, according to the level of

Fig. 2025.



Float-Valve.

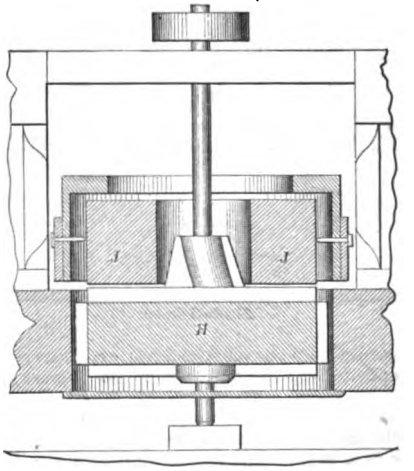
the liquid in the chamber where the float is placed. It is the equivalent of a *ball-cock*.

Flock. 1. Wool-dust used in coating certain portions of the patterns in wall-papers. The wool is the short refuse of the factory, much of it being derived from the cloth-shearing machine. It is scoured, dyed, dried, and ground, sifted into grades, and dusted over the varnished surface of the paper.

2. A fibrous material for stuffing upholstery, mattresses, etc. It is made by reducing to a degree of fineness, by machinery, coarse woolen cloths, rags, tags, old stockings, etc.

Flock-cut'ter. A machine for cutting fiber to a very short staple, called *flock*.

Fig. 2026.



Tilton and Ritson's Flock-Cutter.

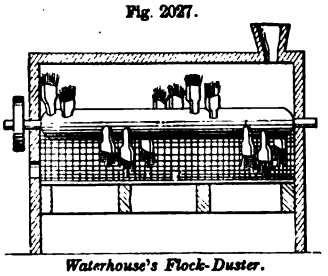
Digitized by Google

In Barber's patent (1846) it consists of a cylinder with spiral knives rotating in contact with a concave having straight knives, the effect being a shear cut upon the fiber passing between the edges, which shave past each other. See also Chase, 1862; Pitts, 1856; Marble, 1872.

The example (Fig. 2026) has a bed in which knives are arranged in parallel groups, of which one in each group is radial and the others of the group parallel therewith. The lower cutter *H* has a rotary motion and a vertical adjustment. The other cutter *J* has a self-adjusting movement, without rotation, but floating, as it were, on the surface of the runner.

Flock-dust'er. For removing dust from flock. The material is agitated by beaters in a gauze cylinder with interior ribs; or it is fed into the hopper at one end of the case and is discharged at the other end, being dusted and loosened by the inclined brushes which impel it forward. The dust escapes through a semi-cylindrical screen.

Fig. 2027.



Waterhouse's Flock-Duster.

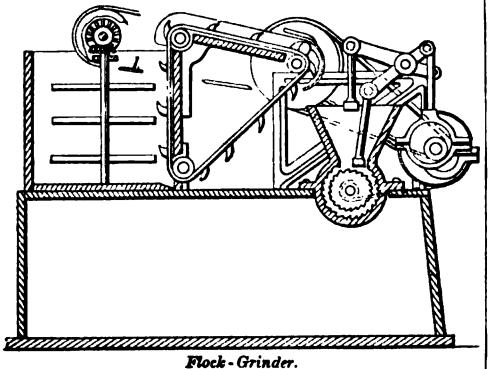
Flock-grind'ing Ma-chine'. A case of the form of a hollow cone, containing a revolving cylinder of the form of the frustum of a solid cone. Both are provided with spirally arranged knives, held between segmental binder-plates. Apertures at both ends are provided, so that the machine may be fed and run in either direction, to sharpen the knives and grind at the same time.

M'Allister's, 1870, has a cylinder of oblique blades operating upon vertical parallel blades on the concave beneath.

In some cases the grinder is a frustum of a cone discharging at the base.

In the example (Fig. 2028), the box has radial agitators on a vertical, rotating shaft. The endless apron passes up one side, and has cups carrying up the material and conveying it to the hopper of the tearing cylinder. The material is forced down upon the tearing cylinder by reciprocal plungers.

Fig. 2028.

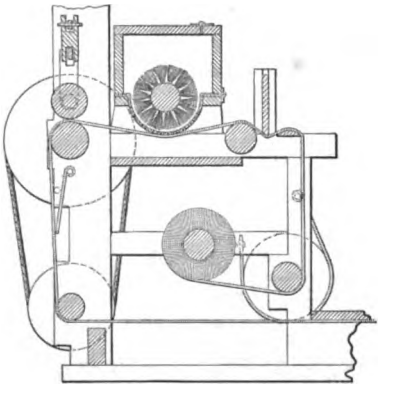


Flock-Grinder.

Flock'ing-ma-chine'. One for distributing flock on a prepared surface of cloth or paper.

In the example, the cloth is passed on an endless web with its varnished side uppermost, beneath a brush whose upper portion rotates in a box of flock.

Fig. 2029.



Chaffee's Flocking-Machine.

Flock-o'pen-er. A machine with pickers or stiff brushes for tearing apart the bunches of flock, so as to make a light, loose fiber which shall feed regularly to the cloth or paper to whose varnished surface it is to be attached.

Flock-pa'per. Wall-paper on which pulverized wool is attached by size.

Flog'ging-chis'el. A chipping-chisel of large size, used in chipping off certain portions of a casting.

Flog'ging-ham'mer. A hammer used by machinists, etc., intermediate in size between the sledge and hand hammer.

Flood-fence. 1. One anchored to prevent its being upset, floated off, or carried away during time of high water; or,

2. One which is laid over by the force of the current, and is prevented by its moorings from being carried away.

Flood-flank'ing. (*Hydraulic Engineering.*) A mode of embanking with stiff, moist clay, which is dug in spits, wheeled to the spot, and then each spit, separately being taken on a pitchfork, is dashed into its place so as to unite with the spit last thrown. The crevices which appear after the contraction of the clay in drying are filled by *sludging*.

Flood-gate. 1. A tide-gate or sluice.

2. *a.* A gate or sluice-door in a water-way, arranged to open when the water attains a hight above a given level, and so allow it to escape freely, to prevent injury by flood.

b. A gate which lies down when the stream becomes deep and powerful, so as to avoid being carried off.

Systems of irrigation including flood-gates, wheels, and pumps, were introduced into Spain by the Saracens. The country is gradually drying up. In the time of Pliny it was more populous and prosperous than now. Since the time of Abderrahman it has become still more dry and sterile.

Flook'an. (*Mining.*) The shifting of a vein or lode by a cleft. *Flooking.*

Floor. 1. (*Building.*) The surface on which a person walks in a room or house.

It may be of masonry, bricks, tiles, concrete, earth, boards.

The term usually refers to boards laid tightly together and nailed to timbers which are termed *joists*.

A *single-floor* (*A*) is one in which the joists *a a*

Digitized by Google

pass from side to side of the house, resting upon wall-plates and sustaining the floor above, and the ceiling of the room below.

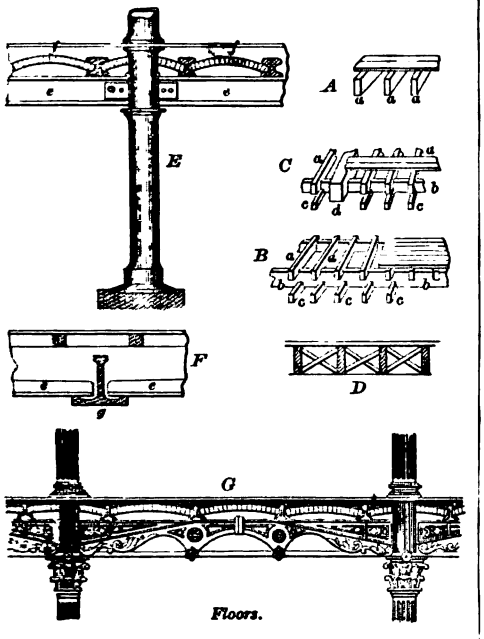
A *double-floor* (*B*) is one in which the primary timbers are binders *b b* which rest upon the wall-plates and support the *floor* or *bridging-joists a a* and the *ceiling-joists c c*.

A *framed floor* (*C*) has an additional member, which assumes the primary position. The *girder d* rests on the *wall-plates* and supports the *binding-joists b*, whose ends rest thereupon. The *binding-joists* support the *bridging* or *floor-joists a* and the *ceiling*-joists *c*, as before described.

Diagonal cross-pieces nailed between the top of one joist and the bottom of the next are called *struts*, and the floor is said to be *strutted* (*D*). The effect is to prevent the lateral deflection or tilting of the joists, and to make them mutually sustaining when an excessive weight is imposed on one or more.

Fire-proof floors (*E*) are usually constructed with iron girders *e* a short distance apart, which serve as

Fig. 2030.



Floors.

abutments for a series of brick arches *f*, on which either a wooden or plaster floor may be laid.

F is a floor with beams *e* supported on iron girders *g*. *G* is a fire-proof floor of brick and cement, supported on iron framing on iron columns. Over the cement is a wooden floor for comfort. It is from the Harpers' establishment in New York.

See also STABLE-FLOOR.

A *folding-floor* is one in which the heading-joints of a number are in a straight line.

In a *straight-joint* floor, each board breaks the joint of the preceding.

A floor without girders, joists, or pillars was laid in Amsterdam for a room sixty feet square. Very strong wall-plates were secured in the walls, and the floor consisted of three thicknesses of one and a half inch boards nailed to the wall-plate. The first two courses were separately laid and nailed diagonally across the space and crossing each other at right angles. The next course was laid in the usual manner, square with the building. The floor was thus suspended, and strained from the wall-plates.

Among the modes of constructing fire-proof floors may be cited girders and beams of cast-iron and trusses of wrought-iron. (See BEAM.) Spanning the intervals between the beams, brick arches are placed, and upon these concrete floors, with a simple covering of boards for comfort or appearance.

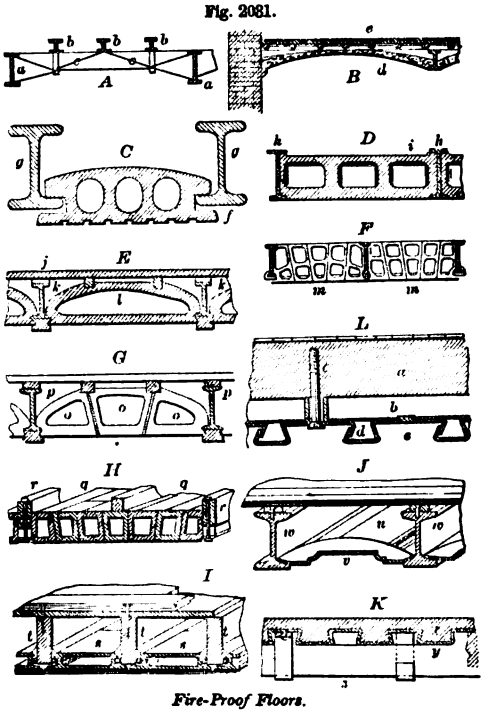
Fig. 2031 shows a number of modes of construction.

A has a truss of three members resting on I-shaped iron girders *a*, and supporting similarly shaped joists *b*, on which a floor is laid.

B has a sprung arch *d* of concrete or béton resting on a skew-back on the wall and the foot flange of the iron girder. On it rest the joists and flooring *e*.

C has hollow bricks *f*, which are suspended from

Fig. 2031.



Fire-Proof Floors.

the foot flanges of the angle-iron girders *g*, and support the ceiling.

D has blocks *i* of cement, concrete, or plaster-of-paris cast on temporary molds between the beams *h* and around cores.

E has arched and hollow tiles *l* which rest on the beams *k* and support the floor *j*.

F has hollow tiles *m* which meet above and below the beams. The tiles are in two tiers, and their thrust is sustained by a tension-rod.

G has arched tiles, three voussoirs *o* in a set, and these rest on the beams *p*.

H has five voussoirs *q* forming a flat arch resting on the beams *r*.

I has ceiling tiles *s* suspended from cleats on the ribs *t*.

J has I-shaped girders *w* supporting tiles whose soffits have coffers and moldings.

K is a roof in which the concrete surface *x* is held by corrugated plates *y* tied to the rafters *z* by angle-pieces.

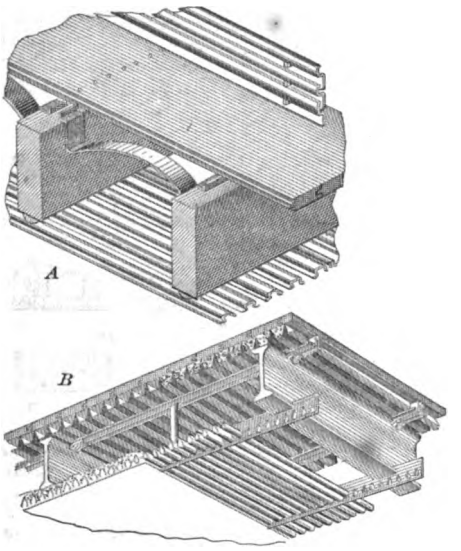
Digitized by Google

L is a similar arrangement for ceilings; *a* the joists, *c* the suspension bolt, *b d* the sheet-iron, *e* the plaster.

In Fig. 2032, *A*, the joists have iron lath, and strips of metal are spiked to the joists to support arches of concrete beneath the flooring. The studding has also metallic lath.

B has girders of iron, with metallic plates for holding the ceiling laths, which are completely covered by the plaster. The floor rests upon con-

Fig. 2032.



Fire-Proof Floors.

crete bedded upon corrugated plates, and these rest upon transverse cross-plates which tie the girders together.

2. The bottom part of the hold on each side of the keelson. The flat portion of a vessel's hold.

3. The inner piece of the two which together form the bucket of an overshot water-wheel. See BUCKET.

Floor-cloth. 1. A heavy painted fabric for covering floors.

The canvas or backing of floor-cloth is a strong textile fabric of hemp or flax, known as *burlaps*. It is woven of a width of from four to eight yards. The pieces of convenient size are stretched in a vertical frame, and size is applied by workmen who stand on ranges of scaffolding in front of the canvas.

It is pumice-stoned to remove asperities. The color for the back is a thick paint laid on with a peculiar trowel. The front is then sized, pumiced, and receives several coats of paint. The pattern was at first stenciled, but since 1780 has been put on with blocks about 18 inches square, one for each color, and the blocks *register* with each other as in calico-printing or paper-staining. The canvas is spread upon a large table. Each block in turn is dipped face downward upon a cushion wetted with paint of the particular color for that block. A layer of paint is thus taken up and transferred to the canvas, as in printing. The colors are applied one by one, occupying their proper places in the pattern, which is made of little square types answering to the pattern and the color.

The *printing-table* is 30 feet long and 4 wide; the roll of painted cloth is underneath it, and is gradually unwound, passing over the surface of the table where the printing-blocks are applied. As it is printed, the cloth slips over the table and hangs down through a slit in the floor, so that it may remain vertical while the paint is drying.

A United States patent has been granted for a printing-block in which each square is represented by a square prism in a chase of the requisite size, say 18 × 18 inches. Each prism is separately movable and may be set out to the plane of the face. Any set of the prisms may be forwarded according to the pattern required.

The art originated with Nathan Taylor, in England, in 1754, at Knightsbridge, near London.

The canvas for the purpose was originally made of ordinary width and the strips sewed together. It was afterwards woven four yards, then seven yards, and eventually nine yards wide.

At the original Knightsbridge factory it is now made in pieces 8 × 20 yards and 7 × 30 yards.

2. An artificial fabric painted, varnished, or saturated with a water-proof material. The kinds are numerous; e. g.:—

Whiting and ocher, mixed with glue dissolved in milk.

Leather scraps treated with alkali, ground, mixed with flax or hemp fiber, and rolled into sheets.

Cotton batting treated with a cement of beeswax, glue, venice turpentine, and boiled linseed oil; covered with a pigment of burgundy pitch, litharge, and boiled linseed oil, colored to suit.

Wall-paper varnished.

Wall-paper on canvas, sized and varnished.

Painted cloth.

Sheets of rubber and cork dust, softened with benzole rolled between two fabrics, a coarse and a fine; the latter is stripped off, leaving the composition attached to the other.

Painted paper.

Duck treated with boiled oil, resin, and cork dust, or saw-dust. Varnished.

Paper printed in oil and varnished with solution of caoutchouc.

Cloth varnished.

Manila paper on both sides of burlaps.

Fabric coated with paper-pulp in the machine.

Roofing-paper treated with warm linseed oil and naphtha, to which is pasted a sheet of wall-paper, varnished.

Burlaps, sheared, damped, calendered, printed.

Paper floor-cloth treated with varnish, having in it powdered felspar or glass.

Fabric covered with paper, treated with oil, resin, and japan varnish. Ornaments of water-color placed thereon and fixed with white glue.

Jute and manila grass combined and colored in stripes.

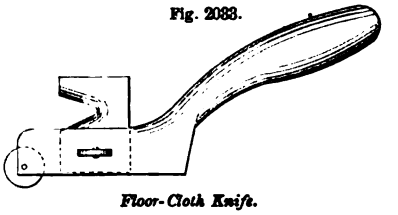
Fabric coated with ground slate or clay; with linseed oil, japan varnish, and paints.

Ground leather, vegetable fiber, and bullock's blood or fibrine, painted, stained, or printed.

Jute fiber printed with aniline.

Canvas sized with glue and painted.

Fig. 2033.



Floor-Cloth Knife.

Digitized by Google

Lamina of wood backed by fabric or paper.

Paper cemented on cloth, printed or grained, and varnished.

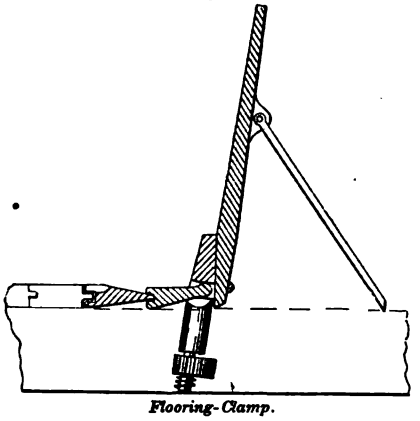
See also LEATHER, ARTIFICIAL.

Floor-cloth Knife. A pushing knife for slitting floor-cloth. The caster keeps it above the floor.

Floor-head. (*Shipbuilding.*) The upper extremity of a floor-timber.

Floor'ing-clamp. An implement for closing up the joints of flooring-boards. In the example, the clamp straddles the joist; is retained by the serrated

Fig. 2034.



Flooring-Clamp.

cams, and the forward thrust of the lever is maintained by a pivoted brace, which engages the joist behind it.

Floor-plan. 1. (*Shipbuilding.*) A longitudinal section, showing the ship as divided at a water or rib-band line.

2. (*Architecture.*) A horizontal section, showing the thickness of the walls and partitions, the arrangement of the passages, apartments, and openings at the level of the principal or receiving floor of the house.

Floor-tim'ber. (*Shipbuilding.*) The lower section of a rib secured between the keel and *keelson*, the flat timbers crossing the keel forming the floor of the hold. The timbers in continuation of the rib are called first, second, third, etc., *futtocks*.

Flop-damp'er. A stove or furnace damper which rests by its weight in open or shut position.

Flo'ran. Fine-grained tin; either scarcely perceptible in the stone or stamped very small.

Flo'ra-scope. A microscope contrived for examining flowers.

Flor'ence-leaf. Fine leaf yellow alloy. See BRONZE-POWDER.

Flor'en-tine. (*Fabric.*) A kind of silk.

Flor'en-tine-re-ceiv'er. A form of receiver (*a*) for the results of the distillation of essential oils. It is conical in form, and has a side spout at which accumulated water discharges as it rises to the level of the bend of the spout, while the oil, which is lighter than water, collects at the top, and may be decanted off.

Fig 2035.

Florentine-Receiver.

Oils heavier than water are collected in the separator *b* and drawn off at bottom.

Flor'et-silk. FLOSS-SILK (which see).

Flosh. (*Metallurgy.*) A hopper-shaped box in which ore is placed for the action of the stamps. The side of the box has a shutter which is raised or lowered to allow the ore to escape when it has acquired the desired fineness.

Floss. Fluid glass floating in a puddling-furnace.

Floss-hole. (*Metallurgy.*) *a.* A hole at the back of a puddling-furnace, beneath the chimney, at which the slags of the iron pass out of the furnace.

b. The tap-hole of a melting furnace.

Floss-silk. The exterior soft envelope of a silkworm's cocoon; the raveled downy silk broken off in the filature. It is carded and spun for various purposes.

Floun'der. A slicking-tool whose edge is used to stretch leather for a boot front in a *blocking* or *crimping board*.

Flour-bolt. (*Milling.*) A gauze-covered revolving, cylindrical frame or reel, into which *meal* or *chop* from the stones is fed, in order to have the flour sifted through and separated from the offal. The cylinder is large and long, and its axis is usually inclined; the bolting-cloth with which it is covered is of different grades of fineness, the meshes at the reception end being closer than towards the discharge. The matters passing through at the different portions of the length are of different grades, and are kept separate.

The "fine-flour" of Scripture was doubtless bolted flour, in contradistinction to unbolted flour or brown meal.

Pliny speaks of sieves of horsehair as first made by the Gauls, and those of linen by the Spaniards. The method of applying "a sieve in the form of an extended bag to the works of a mill, that the meal might fall into it as it came from the stones, and of causing it to be turned and shaken by the machinery, was first made known in the beginning of the sixteenth century" (BECKMANN). The best bolting-cloths used in Germany, when Beckmann wrote, came from England, and were made of wool.

Flour-cool'er. (*Milling.*) A chamber, trunk, or machine in which meal from the stones is placed to cool, or is stirred by a blast before arriving at the bolt.

Flour-dress'ing Ma-chine'. The flour-dressing machine is a hollow, stationary, inclined cylinder or frame covered with wire cloth of different degrees of fineness, 64, 60, 38, and 16 meshes to the inch, the finest being at the upper end. Within the cylinder is a reel whose rails are covered with brushes, which, in their revolution, act against the interior wire surface of the cylinder. The meal is conducted within the cylinder by a spout or hopper, and is thus rubbed through the wire meshes, the finest at the top, the next at the succeeding grade, and so on. The various qualities are collected in the separate partitions of the box.

The machine is described in the patent of John Milne, 1675.

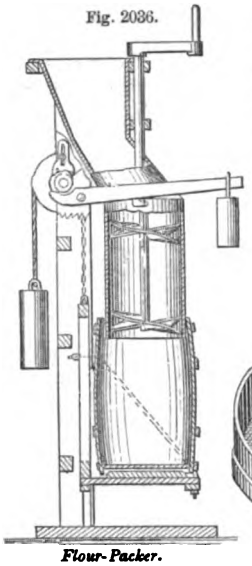
Flour-mill. See GRINDING-MILL.

Flour-pack'er. A machine for compactly filling barrels or bags with flour. It is usually a follower or piston which presses upon the flour, but in some cases the flour as it falls into the barrel is continuously packed by a spiral, as in the example.

The barrel is placed on a platform suspended by a steelyard and by a weighted cord passing over a pulley. The steelyard takes under and clamps another pulley attached to the former one, driving it against a block above. On sufficient deposit of flour the steelyard is depressed, the roller freed

Digitized by Google

Fig. 2036.

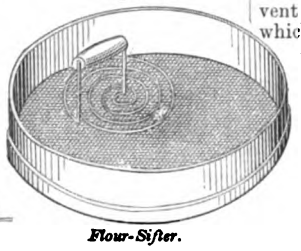


Flour-Packer.

from the upper brake, and the barrel of flour descends.

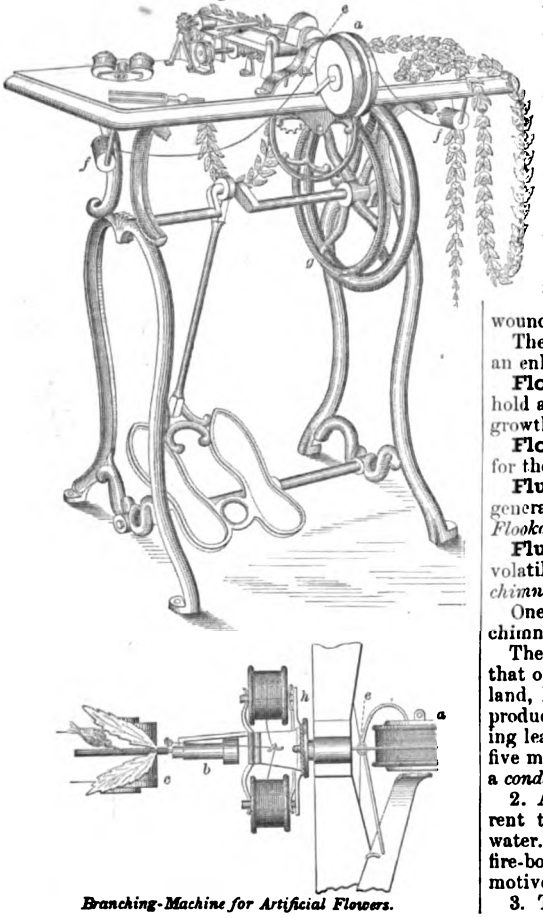
Flour-sift'er. A domestic sieve for separating lumps or accidental trash, such as insects, from the flour of the bin or barrel. As a substitute for the hands, a flat coil of silvered wire is adapted to vibrate over the meshes of the sieve and expel the flour.

Fig. 2037.



Flour-Sifter.

Fig. 2038.



Branching-Machine for Artificial Flowers.

Flow'ers, Ar'ti-fi'cial. Ornaments simulating the natural products of the garden ; made from wire, gauze, cloth, paper, shavings, wax, shell, feathers, etc. Cutting-punches and scissors are used for shaping ; gauffering-presses for stamping into the various graceful shapes and puckers.

The feather-flower makers of South America and Mexico had attained great skill in the time of Cortes. Italy led the way in Europe ; France followed, and now leads.

Fig. 2038 shows a French machine for branching artificial flowers, that is, braiding them or leaves to a stem.

The basis of the stems is wire, and two threads of suitable material are laid along this wire to prevent subsequent slipping of the colored thread, which forms the outer covering of the stems. The ends of the short stems of leaves, flowers, buds, and fruits being laid against the wire are wound under the outer covering, and are thus fastened to it.

The wire is fed from a spool *a*, passes through a hollow spindle *b*, and lies upon an endless feed-belt *c*, to which it is clamped by small pinchers.

The belt is driven by gearing underneath, and carries with it the wire stem, which is slowly unwound from the spool *a*. Two threads, passing through an eye *e*, are also drawn through the hollow spindle *b*, in conjunction with the wire, by the motion of the endless belt. These threads are unwound from the spools *f*. At the same time a rapid rotary motion is given to the hollow spindle by a small belt from the driving pulley *g*.

On the revolving hollow spindle *b* is fixed a spool-frame *h*, which carries two spools. The covering threads are led from these spools through the loop of a small flyer on the end of the hollow spindle *b*, and being held in contact with the wire as the latter is slowly fed through the spindle, are wound uniformly over its surface, the spool-frames revolving with the spindles.

The ends of the stems of leaves, fruits, or flowers being thrust into the ends of the hollow spindle are at once caught, and firmly wound under in a rapid manner.

The upper figure is a general view, and the lower an enlarged view of the principal working parts.

Flow'er-pot. A flaring earthenware vessel to hold a plant with a sufficient quantity of soil for its growth.

Flow'ing-fur'nace. (*Founding.*) Another name for the cupola for melting iron in foundries.

Fluc'an. (*Mining.*) A soft, clayey substance, generally accompanying the cross-courses and slides. *Flookan.*

Flue. 1. A passage for the conveyance of the volatile results of combustion. A *smoke-duct* or *chimney*. See FIREPLACE ; CHIMNEY.

One of a cluster of smoke-ducts in a stack of chimneys.

The longest flue with which we are acquainted is that of the lead-furnaces, Allen Mill, Northumberland, England. It is used for cooling the volatile products of combustion, and condensing the escaping lead fumes. It is 8,789 yards in length (nearly five miles), is 8 feet high, 6 wide. It may be called a *condenser*, so far as the fume is concerned.

2. A pipe for the conveyance of the caloric current through a boiler, to heat the surrounding water. It is usually secured in the sheets of the fire-box and smoke-box respectively, as in the locomotive-boiler. Perhaps invented by Smeaton.

3. The technical abbreviation of *flute ;* used by

Digitized by Google

organ-builders to signify a *flute-pipe*, in contradistinction to a *mouth-pipe* or *reed-pipe*.

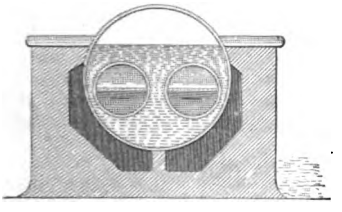
Flue-boil'er. A steam-boiler whose water space is traversed by flues; that is, a tube in which the heated gases are conveyed. There are several varieties, as, *drop-flue; multiple-flue; return-flue*, etc.

Smeaton is credited with the invention. It is now the usual form on our Western rivers; the cylindrical boilers have usually two flues. The fire heat first passes beneath the boiler, and then returns through the flues.

The term *flue*, properly used, distinguishes the boiler from those which have *tubes*, which are full of water, and the heat *surrounds* them, but does not *fill* them.

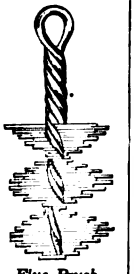
In the boiler represented, the fire is built *in* the flues, and the caloric current returns beneath the boiler.

Fig. 2039.



Fairbairn's Flue-Boiler.

Fig. 2040.



Flue-Brush.

Flue-brush. A cylindrical brush of wire or steel strips used to clean the scale and soot from the interior of a flue, to lay bare the metallic surface.

Flue-clean'er. A brush of wire or steel slips, or a scraper to clean flue surfaces of steam-boilers.

A device by which a jet of steam may occasionally be projected along a boiler flue to blow out the scale of soot.

Flue-ham'mer. (*Coopering.*) One whose *peen* has a working edge, the length of which is in the plane of the sweep of the hammer. It is used in flaring one edge of each iron hoop to enable it to fit the *bulge* of the cask. See PEEN.

Flue-plate. A plate into which the ends of the flues are set.

Flue-scrap'er. An implement having circular or spiral blades to scrape the scale from the fire-surface of flues of steam-boilers.

Flue-sur'face. (*Steam-engine.*) The area of surface of the boiler which is exposed to the action of the flame and heated gases after they have left the fire-chamber or furnace.

The heating surface of a boiler is made up of the *fire-surface* and *flue-surface*.

Fluid-com'pass. (*Nautical.*) That in which the card revolves in its bowl floated in alcohol.

Fluid-lens. One in which a liquid is imprisoned between circular glass disks of the required curvatures.

Attempts to obtain achromatism have been made by using metallic solutions and other liquids having a higher dispersive power than flint glass. Though several of these liquids appear to have given excellent results experimentally, they have never been brought into general use.

Fluid-me'ter. A device to ascertain the quantity of fluid passing a selected point.

Some of these are driven by clock-work or other motor, others by the pressure of the fluid. When this is an elastic body, as air or gas, the question is complicated by the compressibility; when the fluid is such as water, alcohol, or oil, the problem is more simple. See LIQUID-METER.

Among fluid-meters proper may be cited GAS-METERS (which see). As to mechanical construction, they may be described as fans rotating spiral vanes, expanding bags, cylinder and piston, revolving partially submerged meter-wheels, inverted cylinders. See AIR-HOLDER, etc.

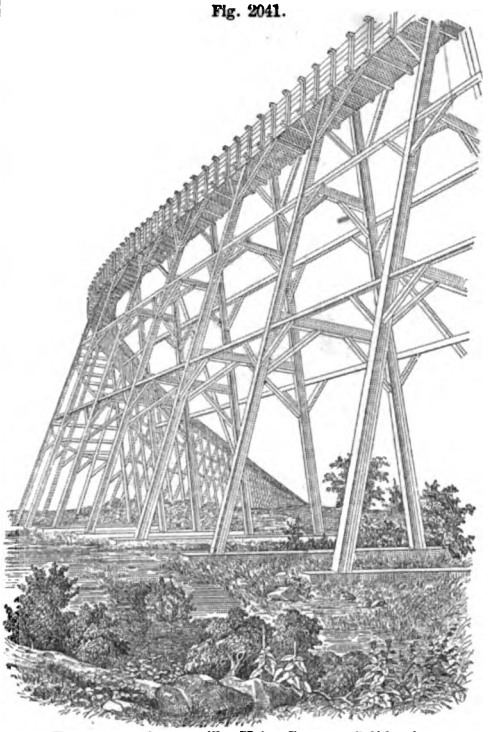
Fluke. 1. (*Nautical.*) The palm of an anchor. The broad, holding portion which penetrates the ground. See ANCHOR.

2. (*Mining.*) The head of a charger; an instrument used for cleansing the hole previous to blasting.

Flume. A chute or penstock, open or covered, for the passage of water to a wheel or washer. Used with water-wheels and gold-washers of various kinds. A *penstock*.

The illustration shows a flume crossing a valley

Fig. 2041.



Flume near Smartsville, Yuba County, California.

in California, uniting the feeder canal on one ridge with the distributing canal of another ridge.

Flu'or-o-type. (*Photograph.*) A process into which fluoric acid enters in the shape of fluorate of soda.

Flush. 1. A term signifying an unbroken or even surface, or applied to surfaces on the same plane.

2. To turn on a sudden dash of water. See FLUSHING.

Flush-bolt. *a.* A screw bolt whose head is countersunk so that it shall not protrude from the surface of the object.

b. A sliding bolt let into the face or edge of a door so as to make an even surface therewith.

Flush-deck. (*Nautical.*) One running the whole length of the vessel, from stem to stern, without forecastle or poop, as in a frigate. The "Great

Digitized by Google

Eastern" has a flush-deck 692 feet long and 83 feet wide.

Flush'ing. 1. (*Hydraulic Engineering.*) To turn on a sudden and copious dash of water as in *flushing a sewer* to cleanse it of silt. When a collected body of water is turned into the channel of a harbor to deepen it and keep it navigable, it is termed *sluicing;* the *sluice* being opened to let the water out of the reservoir. Where the water of a river is dammed to obtain a fall, and the head of water is turned through a sluice-way to increase the depth of water at that point to float a boat on to another level, it is termed *flashing.*

When the water from a dam is suddenly turned by a sluice-way down a ravine, to turn up the earth and stones and expose ore, it is called *hushing.*

2. (*Weaving.*) A term applied to a thread which spans a number of other threads without intersection. (See TWILL.) Usually called FLOATING (which see).

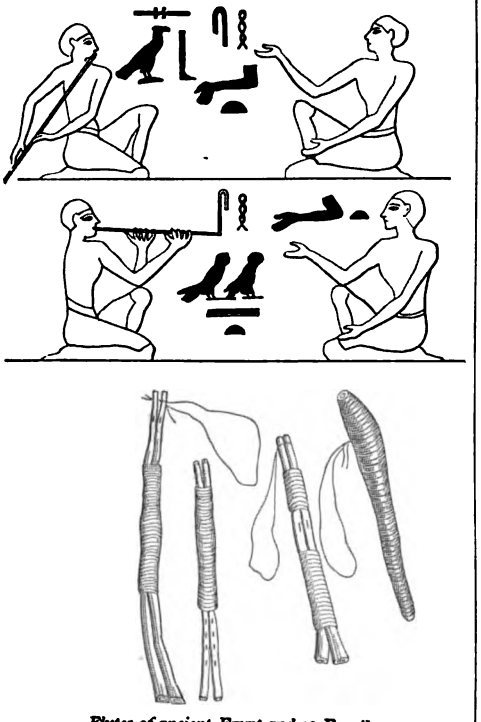
Flush-joint. One in which the abutting parts make no projection beyond the general face of the object.

Flush-pan'el. (*Joinery.*) One whose surface comes out even with the face of the stile.

Flush-wheel. A wheel used in raising water for draining; it is shaped like a *breast-wheel*, but is *driven* by power to raise water. See SCOOP-WHEEL.

Flute. 1. (*Music.*) An ancient wind instrument which had several forms in ancient times, which it still maintains among savage nations. The New-

Fig. 2042.



Flutes of ancient Egypt and of Brazil.

Zealanders play it with a blast through the nose. In some barbarous countries it has two barrels. The mouth-piece is generally at the end, like our clarinet. Captain Speke found one of the native kings of Equatorial Africa proficient after his style.

The instrument called a flute in the translation of the Book of Daniel may have been the pandean pipes, which are very ancient, or it may have been the flute as used in Egypt.

The flute is very common in the paintings of the Egyptian tombs. The accompanying cut is from a painting in a tomb near the Pyramids. The action indicates the side position of the mouth-pieces and holes. Of the chromatic scale we may learn more from what Pythagoras has written, for no doubt he derived his information from the Egyptian priests, who were scientific musicians.

The flutes of ancient Egypt were single and double; the latter are shown on the paintings of Eléythya. In one case the flute is apparently blown through the nostril, like the New Zealand flute.

Herodotus (450 B. C.) mentions the marching of the troops of Alyattes the Lydian "to the sound of pipes and harps, and flutes masculine and feminine." This has been understood to refer to the sexes of the players, but more probably indicates lower and higher musical pitch.

Flutes among the classic Greeks were made of asses' bones, which are said to be remarkably solid. The euphony of the sound may be presumed to be in the inverse ratio of the natural tone of the original proprietor.

The same much-belied animal contributes his hide to the making of drum-heads, which have a fullness of tone highly suggestive of the inflated style of the creature

"Out of whose mouth there issues a blast."

See DRUM. The *ossea tibia* was made of the leg-bone of a crane.

Alcides *loquitur:*—

"The Alexandrians are especially skillful with the flute; and not only in those kinds called girl's flutes and boy's flutes, but also in men's flutes, which are also called perfect and super-perfect; and also in those which are called harp-flutes, and finger-flutes. For the flutes called *elymi*, which Sophocles mentions in his 'Niobe,' and in his 'Drummers,' we do not understand to be anything but the common Phrygian flute. And these, too, the Alexandrians are very skillful in. They are also acquainted with the flute with two holes, and also with the intermediate flutes, and with those called *hypotreti*, or bored underneath.

"We know of some that are called *half-bored*, which Anacreon mentions:—

'What lust has now seized thus upon your mind,
To wish to dance to tender half-bored flutes?'

And these flutes are smaller than the perfect flutes. I am acquainted, too, with other kinds of flutes, the tragic flute and lysiodic flute [used by the actor personating a female] and the harp-like flute; all which are mentioned by Ephorus in his 'Inventions,' and by Euphranor the Pythagorean in his 'Treatise on Flutes,' and also by Alexon, who wrote another treatise on 'Flutes.' But the flute called *tilyrinus* among the Dorians in Italy, and the flute *magadis* [a Lydian instrument], sends forth a sharp and a deep note at the same time, as Anaxandrides says in his 'Armed Fighter':—

'I will speak like a *magadis*, both loudly and gently.'

And the flutes called *lotus-flutes* are the same which are called *photinges* by the Alexandrians; and they are made of wood growing in Libya. But Juba says that the flute which is made out of the leg-bones of the kid is an invention of the Thebans; and Tryphon says that those flutes which are called *elephan-*

Digitized by Google

tine [ivory] were first bored among the Phœnicians." — *Deipnosophists*, by ATHENÆUS, A. D. 220.

"The Phrygian *deep-toned flute* had a bell mouth, like a trumpet." — *Ibid.*

So they had no lack of flutes and writers on the same 2,000 years ago.

Flutes are extensively made and used by the Brazilian natives. The bones of which they are made are yellow, jagged, and far from inviting to delicate lips. Their tones, however, are singularly soft and mellow. The largest has two bones, each 12 inches long and ⅜ inch bore. They are united by twine neatly wound and worked. On the back of the lower part are finger-holes, shown in Fig. 2042. The whistle part is constructed by a cone of resinous cement beneath the mouth-orifice, the ridge of cement rising to the center of the tube. The instrument is played by blowing through the upper end, as in a clarinet. A smaller flute is made to play by blowing in at either end. Another has a swelled, wooden mouthpiece, and no side opening. Dual bone-flutes with finger-holes are yet used in the northern provinces of Brazil; besides bamboo flutes and instruments, with which the voices of wild beasts are imitated with singular accuracy.

The Peruvians, among a multitude of musical instruments, had flutes of various sizes, the tambourine, and the *tinga*, a kind of guitar with five or six strings. They had also a *syrinx*, or pan's reed, with eight pipes, — one more than the classical and the modern.

The flute, as we now know it, was long known as the *German flute*, having one end closed by a plug, the mouth-orifice being on the side. The common varieties of this flute have six open holes and a seventh closed by a key, as in oboes, bassoons, etc.

Fig. 2042.

Flute.

Flutes are now made with from seven to ten keys, by which the fingering of many musical passages is much facilitated.

Flutes are made of hard wood, ivory, glass, metal, or vulcanized rubber.

In the Smithsonian Institute, Washington, is a Guiana native flute made of the thigh-bone of a tiger.

Vaucanson's automaton flute-player was a life-sized figure dressed in the habit of the period (1730), and standing on a pedestal. The figure and the stand were filled with the machinery. The figure was wound up with a key, and played music on a real flute. Air was emitted at the mouth of the figure and projected into the mouth-hole of the flute. The force of the blast was proportioned to the loudness or softness required, and we presume the size and perhaps shape of the embouchure formed by the lips was varied according to the pitch and perhaps the timbre. The details of the invention in this respect have not come down to us. The fingers were made of some elastic material, and were made to stop the holes in the order required. The compass of the machine is not stated, nor the number of tunes within its repertoire.

In a flageolet-player subsequently made by the same artist, the number of holes was but three, and the variation of the pressure on the bellows was from one ounce for the lowest to fifty-six pounds for the highest.

About 1820 two automaton flute-players were exhibited in London. They played eighteen duets.

2. (*Architecture.*) *a.* A long vertical groove in the shaft of a column.

It is usually circular in section, but, when angular, the shaft is called a *canted* column.

The Doric column has twenty flutes.

The Corinthian, Ionic, and composite have each twenty-four flutes.

The Tuscan none.

b. A hollow, concave chamfer, gutter, groove, or channel; the receding member of a compound molding.

3. A species of ruffle.

4. A *stop* in an organ.

Flute-bit. A wood-boring tool adapted to be used in a brace, and used in boring ebony, rosewood, and other hard woods. See BIT; BORING.

Flute-or'gan. (*Music.*) An organ in which the sound is produced by the action of wind on a cutting edge, in contradistinction to the *reed-organ*, in which the sound is produced by a vibrating tongue of metal. See REED-ORGAN.

The *flute-pipe* has a hollow *foot* to conduct the wind to the *body*, which is fastened thereto. Between the *foot* and the *body* is a diaphragm with an aperture through which the wind escapes, coming in contact with the upper lip of the mouth and being set in vibration, thereby causing the sound. As in the flute, the quality of the sound is governed by the proportions of the pipes.

The pipes are made of metal or wood, are generally cylindrical and open at the end.

The wooden pipes are square in section, their ends being stopped with *tompions*, whose distance from the lip modulates the tone, as in the flute.

The longer the pipe the graver the sound, — like the flute again, as may be observed by blowing it after stopping all the side holes in the flute with the fingers, and again after raising the fingers.

The *flute-organ* is also called the *mouth-organ*, and the *mouth* or *flute pipes* are technically known as *flues;* a contraction of *flutes*.

Flute-pipe. (*Music.*) An organ-pipe having a sharp lip or *wind-cutter* which imparts vibrations to the column of air in the pipe, producing a musical note. See MOUTH-PIPE.

Flute-stop. (*Music.*) A stop of an organ in unison with principal, and tuned one octave above *open-diapason*. See STOP.

Flu-ti'na. A kind of accordeon resembling the concertina.

A form of melodeon. An instrument worked by a bellows and keys in bank, and having one set of reeds.

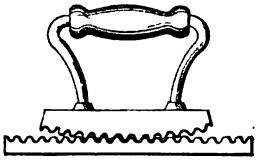
Flut'ing. 1. A species of ruffle.

2. One of the longitudinal grooves in a screw-tap, giving cutting-edges to the thread. See FLUTE.

Flut'ing-cyl'in-der. One having longitudinal grooves to corrugate, crimp, or flute thin sheet-metal plates or fabrics.

Flut'ing-i'ron. A species of laundry-iron which flutes the clothes. In the example, the iron has a segmental corrugated face, and works upon a flat corrugated bed.

Fig. 2044.



Fluting-Iron.

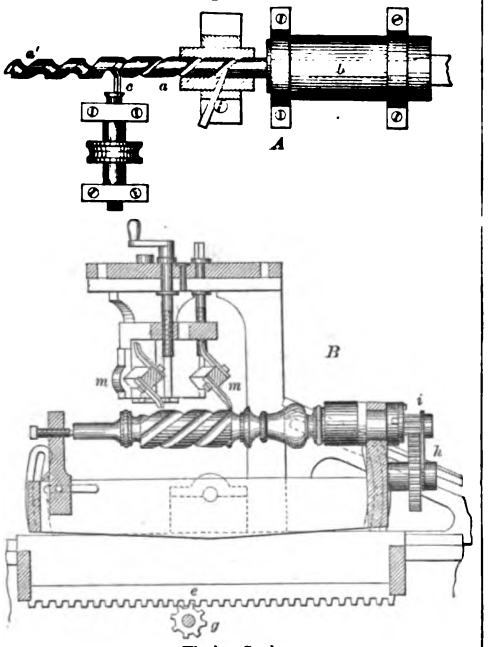
An *Italian*-iron; a *gauffering*-iron.

Flut'ing-lathe. One which cuts flutes or scrolls upon columns or balusters. The *flute* proper is the vertical groove in a

Digitized by Google

column or pillar, but the flute of the lathe is a spiral. Several forms of machines are adapted to this purpose. One is allied in its principle to the rifling-machine, as in January's patent, 1829. The baluster is fed endways against a lateral tool, being rotated on its axis at such a rate as shall impart the number of turns or part of a turn to the foot in length. Of this kind is Fig. 2045 (*A*), in which the piece *a*

Fig. 2045.



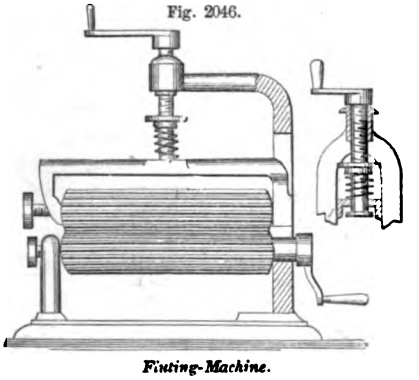
Fluting-Lathes.

to be cut is moved longitudinally through the holder *b*, and at the same time is rotated so that the tool *c* in its revolutions may cut the spiral groove shown at *a'*.

B is a fluting-lathe in which a pair of cutters revolves in a plane oblique with the line of motion of the baluster. The latter is moved longitudinally by the rack and pinion *e g*, and rotated by the wheel and pinion *h i*; the cutters *m m* rotating in parallel planes cut two groves at once.

Flut'ing-ma-chine'. One having a pair of rollers, each one having projections which enter the interdental spaces of the other. By turning the operating screw, the bent bar, and with it the upper roller, can be adjusted up or down at will to regulate the distance between the two rollers.

Fig. 2046.

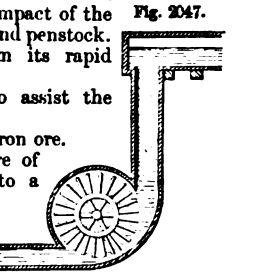


Fluting-Machine.

Flut'ing-plane. (*Joinery.*) A plane adapted to cut grooves.

Flut'ter-wheel. A water-wheel of moderate diameter placed at the bottom of a chute so as to receive the impact of the head of water in the chute and penstock. Its name is derived from its rapid motion.

Fig. 2047.



Flutter-Wheel.

Flux. A salt added to assist the fusion of a mineral.

Limestone is used with iron ore.

Crude flux is a mixture of niter and tartar added to a metal in the crucible.

White flux is obtained by projecting, in small portions at a time, equal parts of niter and tartar into a red-hot crucible.

Black flux has double the proportions of tartar, and the resulting product is dark colored.

Mowean's flux consists of pulverized glass, 16 parts; calcined borax, 2 parts; charcoal, 1 part.

Lime acts as a flux, when in excess, in brick-making.

Lime, *soda*, *potash*, *lead*, *borax*, are used as fluxes in glass-making.

Fluor-spar is used in certain metallurgic operations.

The fluxes used by solderers are, —

Borax.	Venice turpentine.
Sal-ammoniac.	Tallow.
Chloride of zinc.	Gallipoli oil.
Resin.	

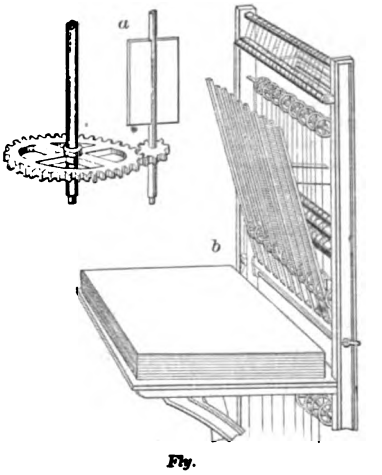
Flux-spoon. (*Metallurgy.*) A small ladle for dipping out a sample of molten metal to be tested.

Fly. 1. (*Horology.*) A regulating device (*a*) used formerly in clocks, and latterly in musical boxes, to control the rate of speed.

The vanes impinge upon the air and meet with a resistance depending upon their area, radial width, angle, number, and speed. By changing these conditions, or any of them, the rate of going of the machine may be regulated; the resistance of the air increasing in a very rapid ratio.

The device is still used in the striking parts of clocks and watches.

Fig. 2048.



Fly.

Digitized by Google

In musical boxes the position of the wings is adjustable, so as to vary their angle of impact upon the air, thus increasing or diminishing the resistance of a given surface of wing and modifying the speed.

This regulator was probably the first device attached to the going works of a clock, many centuries before the oscillating arm or the pendulum were adapted to the purpose. See PENDULUM.

Among the clocks thus regulated may be cited that of Richard of Wallingford, abbot of St. Albans, A. D. 1380. It is likely that the clock erected in the Old Palace-Yard, London, in 1288, and that of Canterbury Cathedral, A. D. 1292, were similarly constructed. To go a step farther back, we may suppose that the clocks presented by Pope Paul I. to Pepin of France, A. D. 760, and to Charlemagne by the Caliph Haroun Al Raschid, A. D. 810, were of similar construction ; or perhaps were clepsydras.

2. (*Printing.*) A vibrating frame *b* with fingers, taking a printed sheet from the *tapes* and delivering it on to the heap.

3. (*Knitting-machine.*) Another name for the LATCH (which see).

4. (*Spinning.*) The arms which revolve around the bobbin in a spinning-frame, to *twist* the roving or yarn which is wound on the bobbin. See FLYER.

5. (*Machinery.*) A FLY-WHEEL (which see).

6. (*Weaving.*) A shuttle driven through the shed by a blow or jerk.

7. *a.* The length of a flag from the staff to the outer edge. The perpendicular hight is the *hoist.*

b. The part of a flag beyond the *jack*, which occupies the upper left-hand corner. See FLAG.

8. (*Nautical.*) A compass-card having marked upon it the points or rhumbs, thirty-two in number. The card is moved by a magnetic-needle beneath. The angle of the ship's course with the magnetic meridian is shown on the marginal plate by a line called the *lubber's line.* See MARINER'S COMPASS.

9. A kind of carriage ; usually a closed vehicle plying for hire and drawn by one horse.

10. A certain part of theatrical stage scenery.

11. The swinging weighted arm of some kinds of presses. See FLY-PRESS.

12. A factitious insect as a bait for fish in angling. A *hackle.*

Fly-block. (*Nautical.*) A large flat block, double or single. The double block sometimes has two sheaves at one part and one sheave in the other portion. Used in the hoisting-tackle of yards.

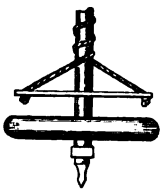
Fly-board. (*Printing.*) The board upon which the printed sheets are laid by the *fly.*

Fly-boat. 1. A rapid passenger-boat on canals.

2. A large, flat-bottomed Dutch coasting-vessel. An ironical term.

Fly-drill. One having a reciprocating fly-wheel which gives it a steady momentum. The driving power consists of a cord winding in reverse directions upon the spindle as it rotates first in one direction and then in the other.

Fig. 2049.



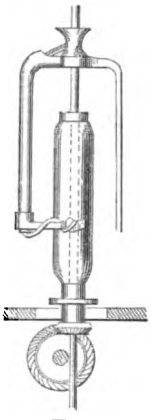
Fly-Drill.

Pressure on the end of the spindle keeps the drill to its work. The fly-wheel pulsates like the balance-wheel of a watch, and as it reaches each end of its stroke the cord has become wound on the spindle, so as to be ready to communicate the impulse in the other direction, by a pressure on the bar which unwinds the cord by rotating the spindle. A relaxation of pressure on the bar allows the spindle to pass beyond the point of unwinding, and the cord winds upon it in a reversed spiral.

This drill may be run by a bow.

Fly'er. 1. A contrivance with arms which revolves around the bobbin in the *bobbin and fly* frame, or the *throstle-frame*, which machines draw and twist the *sliver* into a *roving*, or the latter into *yarn.*

Fig. 2050.



Flyer.

The *flyer* fits on to the top of the spindle, and one arm (in the *bobbin and fly* frame) is made hollow to form a passage for the yarn, which enters at the cup above the top of the spindle, and after a turn or two round the end of the arm is distributed on the bobbin. In the throstle-frame the roving entering above is wound *round* the arm of the *flyer*, instead of passing *through* a *tubular* arm. See THROSTLE.

The flyer rotates with the spindle, and their rotation gives the twist to the yarn. The bobbin is independent of the spindle motion, but in roving-machines has a surface motion equal to the rate of delivery of the yarn from the drawing-rollers. See ROVING. The same also occurs in the BOBBIN AND FLY FRAME (which see).

In the *throstle*, the winding occurs by the detention of the bobbin, which rests on the *copping-rail*, the bobbin being dragged around by the yarn proceeding from the end of the *flyer*, the resistance to revolution on the part of the bobbin effecting the winding. See THROSTLE ; EQUATORIAL BOX.

2. The fan-wheel on the vane of a windmill cap which rotates the latter as the wind veers. See CAP.

3. A step in stairs that ascend in one inclined plane, without winding.

A straight reach of stairs. A *flight.*

4. (*Printing.*) A vibratory rod with fingers which take the sheet of paper from the tapes and carry it to the delivery-table, the sheet resting flatly against the flyer-fingers by the resistance of the air. See FLY.

Fly'er-lathe. (*Weaving.*) A *lay*, *lath*, or *batten* for beating up the weft into the shed, compacting it. Specifically, it may mean a suspended lathe, as distinguished from the batten in a frame journaled below.

Fly-gov'ern-or. One which regulates speed by the impact of vanes upon the air. A *fly.*

Fly'ing-ar-til'ler-y. Field artillery when the gunners are all mounted ; either on horses, or on the limbers.

Fly'ing-bridge. A temporary bridge, suspended or floating. A military, ponton, or boat bridge. See BRIDGE for varieties.

Fly'ing-but'tress. A structure spanning the roof of an aisle between an outer buttress and the wall of the nave. It assists in resisting the thrust of the roof.

Fly'ing-jib. (*Nautical.*) A sail extended by the flying jib-boom beyond the standing jib.

Fly'ing Jib-boom. (*Nautical.*) An extension of the jib-boom. It is sometimes in one piece with the latter, and sometimes connected therewith by means of a boom-iron, in a manner analogous to that of the jib-boom on the bowsprit.

Fly'ing-ma-chine'. To Dædalus, who is said to have flourished about 1300 B. C., is ascribed the invention of the first flying-machine. Being de-

Digitized by Google

sirous of escaping from the wrath of Minos, king of Crete, and no method of sea conveyance presenting itself, he resolved to attempt flight through the air, and made accordingly wings of feathers united by wax for himself and his son Icarus. They ascended into the air, and Dædalus arrived safely in Sicily, but Icarus rose too high, and approaching too near the sun, the wax of his wings was melted, and, the uncemented fabric falling asunder, the rash youth fell into the sea and was drowned. Notwithstanding the multiplicity of attempts which have been made to accomplish the feat of rising above the earth by means of wings, Icarus remains a solitary warning of the danger of approaching too near to the sun.

Roger Bacon asserted in his time that there existed a flying-machine; he had never seen it himself, nor did he know any one who had seen it, but he knew the name of the inventor.

In 1709, Gusman, a Portuguese monk, constructed a machine in the form of a bird. He was pensioned for this, and was thus perhaps enabled to rise in the world, which his machine signally failed to do. Not discouraged, however, in 1736 he constructed a wicker basket covered with paper, which rose to the hight of 200 feet in the air, by which he gained at least fame, if not money, for he was afterwards reputed a sorcerer.

It was in 1783 that the Montgolfiers discovered that the lesser specific gravity of heated air created an ascensive force by which heavy objects might be raised through the atmosphere; and in less than a month afterwards hydrogen gas, which had then been known for about seventeen years, was successfully employed in a balloon for the same purpose.

This seemed to render the idea of aërial navigation more feasible, and accordingly Blanchard, one of the earliest aëronauts, on his first ascent from Paris in March, 1784, provided his balloon with wings and a rudder, but found them useless. After this we hear little of attempts to guide or propel balloons through the air until about 1843, when Mr. Monck Mason proposed the Archimedean screw as a motor, and constructed an egg-shaped balloon, which was placed on a wooden frame in the form of a canoe, with an Archimedean screw at one end and an oval-shaped rudder at the other. A model of this machine, set in motion by a screw moved by clock-work, was propelled around a room by this means; but the larger machine appears to have met the fate of all its kindred contrivances.

About the same time, a Mr. Henson, in England, patented a machine consisting of a car attached to a huge, rectangular, wing-like frame, covered with oiled silk or canvas, and to be propelled by a steam-engine in the car working two vertical fan-wheels with oblique vanes; while a frame like the tail of a bird was to act as a rudder, and make the apparatus ascend or descend at pleasure. It did not ascend.

In 1850, a Mr. Bell ascended from Kennington, England, in an "aërial machine" in the form of a prolate spheroid, which, it is said, he propelled by a screw, and steered by means of an apparatus for that purpose, during a flight of nearly thirty miles. If this be so, it must have been probably owing to the serenity of the atmosphere.

During the same year, M. Julien at Paris made a model balloon, shaped like a fish, which was made to move in the air by clock-work operating a pair of wings. The model was four yards long, formed of gold-beater's skin, and filled with gas.

A similar machine on a large scale had been tried in England some twenty years before, and failed, though a model of it had been to a certain degree successful.

Mr. Petin, a countryman of Julien's, projected at the same time (1850) a "system of aërial navigation." Certainly a high-sounding name; but then the machine itself was to be on a large scale. It was to consist of an immense framework 480 feet long, supported by four balloons, each 90 feet in diameter, was to have four parachutes, and a platform for passengers. Two horizontal screws were provided for its propulsion. See BALLOON.

Fly'ing-pin'ion. (*Horology.*) The fly of a clock.

Fly-net. 1. (*Menage.*) A net of meshes, or a fringe of leather strips, to protect a horse from flies.

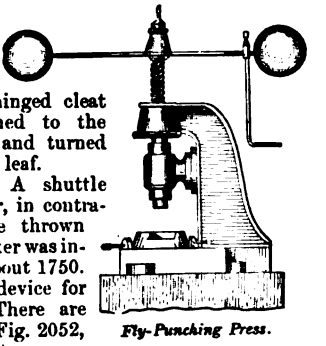
2. A net in an open window to prevent entrance of flies and other insects.

Fly-nut. A nut with wings, to be twisted by the hand; as the screw-nut of a hand-vise.

Fly-press. A screw-press in which the power is derived from a weighted arm, swinging in a horizontal plane, as in embossing and die presses. Presses of this kind are used in making buttons, washers, flat links for chains, cutting and gumming saw-teeth, making percussion-caps, steel-pens, etc.

Fly-punch'ing Press. A press for cutting teeth on saws and for other purposes. The *fly* is the weighted lever, which acquires an impetus in its descent.

Fig 2051.



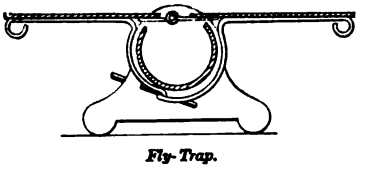
Fly-Punching Press.

Fly-rail. A hinged cleat or bracket attached to the frame of a table, and turned out to support the leaf.

Fly-shut'tle. A shuttle driven by a *picker*, in contradistinction to one thrown by hand. The picker was invented by Kay, about 1750.

Fly-trap. A device for catching flies. There are several forms. In Fig. 2052, the faces of the bait-pans are brought together by spiral springs on the removal

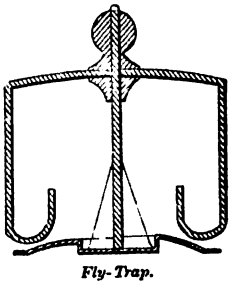
Fig. 2052.



Fly-Trap.

of the detent-pin. On separating the pans for re-setting, the flies drop into the receiver beneath.

Fig. 2053.



Fly-Trap.

Another form is that in which the flies unconsciously walk into a *cul-de-sac*, whence they fail to find a way of retreat.

Other forms have rollers baited and turned by clock-work so as to gradually carry the flies around into the gauze trap or to a position from whence they drop into the drowning-tray.

Fly-wheel. A heavy wheel attached to machinery to equalize the movement. By its inertia it opposes any sudden accelera-

Digitized by Google

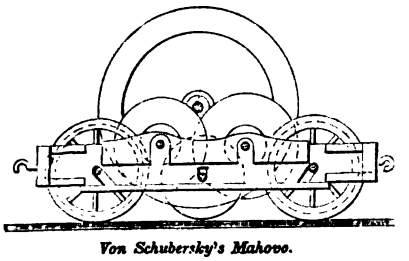
tion of speed, and by its momentum it prevents sudden diminution of speed; in the latter case it acts as a store of power to continue the movement when the motor temporarily flags, or in passing dead centers when the motor is inoperative.

Fly-wheels were first mounted with teeth on their peripheries, to act as first motions, by Fairbairn of Manchester, England.

The fly-wheel attached to the engine set up at Millwall by Boulton and Watt, for rolling armor-plates, weighs 100 tons.

The *Mahovo* is the name given by the inventor, Captain C. Von Schubersky, of Russia, to an adaptation of the fly-wheel to accumulate a reserve of force to be used at intervals when a greater power is needed.

Fig. 2064.



Von Schubersky's Mahovo.

A pair of heavy cast-steel fly-wheels have an independent truck of their own, which is introduced into the train immediately behind the engine. The truck has three pairs of running-wheels approaching each other very nearly by their circumferences. In the intervals between these wheels are placed two pairs of friction-wheels resting immediately on them; and in the interval between these rests upon their circumfefences the large axis of the mahovos; the huge fly-wheels themselves overhanging the truck upon the two opposite sides. When the train moves, the running-wheels impart motion to the friction-wheels, and the latter transfer this movement to the fly-wheels. The diameters of the wheels, and that of the axis of the fly-wheels where it rests upon them, are so related that a velocity of 18.6 miles in the train will generate in the circumference of the fly-wheel a rotary velocity of 466 feet per second; and as the fly-wheels themselves weigh 26 tons, it is computed that, with this velocity, they will embody a living force of 144,000,000 foot-pounds.

As the train moves from rest, the velocity of the fly-wheels is gradually accelerated until it attains a maximum corresponding to the maximum velocity of the train. If steam be now shut off, the fly-wheels become a source of power, and will return the work stored up in them. To stop the train without expending this accumulated force, the friction-wheels are raised out of contact with the driving-wheels. In ascending a grade, the force of the fly-wheels comes in as auxiliary to that of the engine.

Foam-cock. (*Steam-engine.*) A cock at the water-level to blow off scum.

Foam-col-lect'or. (*Steam-boiler.*) A pan or other device at the water-level in the steam-boiler, to catch, retain, and discharge the foam which rises to the surface of the water.

Fo'cal Length. (*Optics.*) The distance between the object-glass and eye-glass of a telescope.

Fo-cim'e-ter. (*Photography.*) An instrument for assisting in focusing an object in or before a camera. This consists usually of a lens of small magnifying power. Formerly, when the fact that the actinic spectrum was mainly outside of the violet end of the spectrum was not properly understood, and lenses were not corrected so as to make the visual and chemical pictures coincident, an instrument was used to determine the amount of movement necessary to throw the actinic picture upon the sensitized plate, subordinating the visual image.

In Claudet's instrument, a number of objects are arranged in a spiral form around the horizontal axis at different distances, so as to be all visible at once from the lens. If, when one of them is in the exact visual focus, another is found to come out more distinctly in the photograph, the discrepancy evidences that the visual and actinic foci do not coincide, and the glass should be rejected.

G. Knight's plan was to place a sheet of negative paper in an inclined position in the camera. A printed sheet being placed before the camera and a picture taken, the relative clearness of the image will determine the true photogenic focus.

Fo'cus-ing-glass. (*Photography.*) A glass used for magnifying the image on the ground glass in the camera, to enable the operator to get it in better focus.

Fog-a-larm'. (*Nautical.*) An audible signal warning vessels from shoals or other dangerous places. Fog-alarms are various in their kind, their operation, and their construction. As to kind, they consist of bells, whistles, and trumpets. As to operation, they are sounded by the current, by the ebbing and flowing tide, by the swaying of the waves, by the wind, by bellows, by clock-work impelled by weight or spring. As to construction, they are adapted for headlands, light-ships, buoys, or to be anchored by piles on spits, sand-bars, or shoals.

A somewhat notable signal of this kind was the bell on the Inchcape Rock, which was placed there by the "good old abbot of Aberbrothock," as sung by Southey in his ballad of "Ralph the Rover." The bell or its clapper was swung by the motion of the waves, and was anchored to the dangerous submerged rock, in the track of navigation in the Frith of Forth. A substantial lighthouse now stands on the rock, which is named from the bell formerly placed on the spot by the courageous, pious monks.

In *A* the apparatus is erected on the deck of a ship which is moored in the position required. From posts on the hull is suspended a pendulous frame which is swung back and forth by the motion of the vessel. A transverse bar in the lower part of the swinging frame actuates the wheel, which is journaled between the pendent arms. Thus the motion of the frame partially rotates the wheel and rings the bell, by means of a band passing over the wheel and over a pulley on the bell-shaft. In *B* the clapper is moved by cam-wheel actuated by chains, which run over pulleys as the float-arm rises and falls by the motion of the waves.

Another form is a bell-buoy with paddles which move the clapper. The clapper of another is moved at regular times by a train of clock-work.

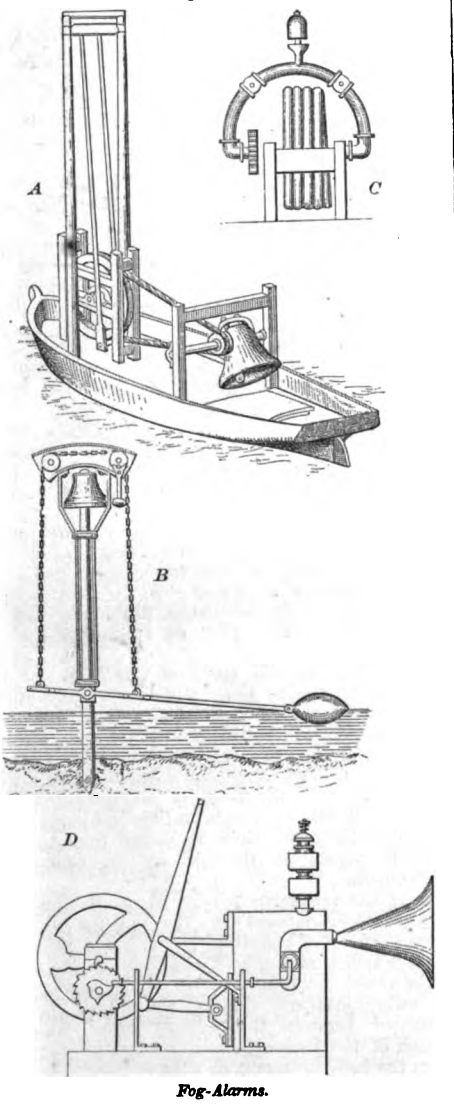
C has a spiral coil of tubing journaled upon standards, and oscillating by the motion of the vessel. Each end of the spiral has a whistle and a valve opening inward. The coil contains a quantity of water, which, as the coil is oscillated, changes its position, and forces the air out through the whistles with a prolonged sound.

In *D* the air is mechanically condensed and stored in a reservoir. The cam on the rotary shaft actuates

Digitized by Google

the valve for the purpose of varying the sounds, to give a series of audible signals more intelligible than mere independent sounds repeated. A trumpet and whistle are attached to connecting pipes proceeding

Fig. 2055.



Fog-Alarms.

from the reservoir. The valve governs the air-aperture in the pipe leading to the trumpet.

Among other devices may be cited: —

One drives compressed air or steam through perforated, rotating disks or plates. The sound-trumpet has a parabolically shaped extension.

Another has cylinders provided with interior clapper-valves near the heads; these admit air when the water recedes, but prevent its escape at the valve-way when the water rises; the air has its exit through the whistles, and sounds the alarm.

Another has two whistles and a single mouth-piece, the aim being to produce discordant sounds, which arrest attention.

A very large fog-whistle, worked by a ten-horse-power engine, is placed on Thatcher's Island, off Salem, Mass.

Fog-bell. A bell upon a vessel, buoy, or spit of land, and rung by the motion of the waves or force of the wind, as a warning to mariners. See FOG-ALARM.

Foge. (*Mining.*) A forge for smelting tin. (Cornwall.)

Fog-horn. See FOG-ALARM.

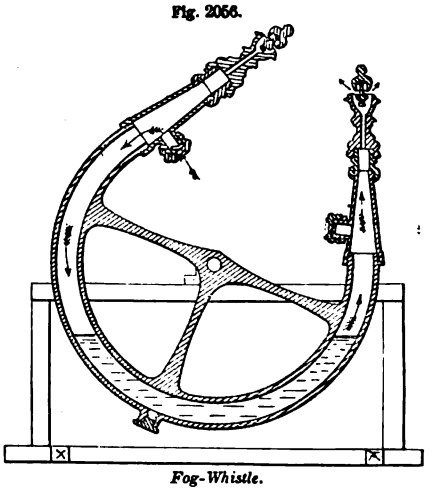
Fog-trump'et. A horn or trumpet placed on a projecting headland, a vessel, or a spar, and blown by mechanical means or by the wind, as a warning to mariners. See FOG-ALARM.

Fog-sig'nal. A detonating ball placed on a railroad track, to indicate danger ahead to the engineer of a passing train.

For nautical, see FOG-ALARM.

Fog-whis'tle. (*Nautical.*) A signal of warning for vessels off a coast. A sounder on the principle of the steam-whistle is exposed to a blast of air or of steam, according to the facilities of operation. Usually, motion derived from the waves, the tide, the wind, or clock-work, make it automatic. In

Fig. 2056.



Fog-Whistle.

the example, the semicircular tubular vessel is mounted upon a rock-shaft, and has at each extremity an ordinary whistle and a valve opening inward. When the vessel is partially filled with water and rocked to and fro, the air is forced through the whistle and sounds an alarm.

On dit: The most powerfuf log-whistle in America is at Cape Fourcher, N. S. It can be heard fifteen miles in clear weather, and twenty-five with the wind.

Foil. 1. A thin leaf of metal, for plating, or to color a gem behind which it is placed. A colored foil imparts its tint to a gem whose natural color is vague and insipid.

Foil is made by rolling into thin sheets a plate of copper covered with a layer of silver. The silver surface is polished and covered with a clean varnish, colored or white.

Tin or lead foil are very thin sheets.

2. An amalgam of silver and tin at the back of a looking-glass.

3. A blunt weapon for fencing. A thin blade with a button on the end.

4. A leaf in architecture or carving; as a trefoil ornament; or a window, having lobes like clover.

Digitized by Google

Fold. 1. A fenced-in inclosure for stock.

2. A doubling of fabric; a *plait;* a *hem.*

Fold'ed-an'gle Joint. See ANGLE-JOINT, Fig. 221.

Fold'er. 1. An ivory or bone blade, used in folding sheets for binding; also in forwarding sheets from the pile in feeding to presses.

2. A form of spectacles in which the lenses fold together for the pocket, and grasp the nose by a spring bow or stiff joint when in use.

Fold'ing. The process by which printed sheets are so doubled up as to bring the pages into consecutiveness for gathering and binding.

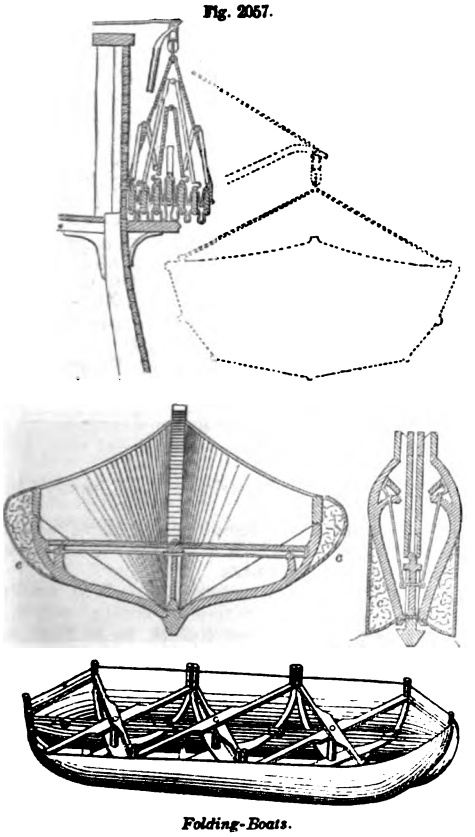
Sheets are of varying sizes, as *demy, medium, royal, imperial,* etc.

The number of pages to each side of the sheet is indicated by the name 4to, 8vo, 12mo, 16mo, 24mo, 32mo, 48mo. The *folio* sheet has two pages on each side and is once folded.

The size of the book will therefore depend upon the size of the paper and the number of times it is folded. Each distinct sheet of a book has a certain mark, called a *signature.* These are *gathered* consecutively to form the book.

Fold'ing-boat. One whose frame is collapsible for compact stowage, either on shipboard or for

Fig. 2057.



Folding-Boats.

transportation on land. In a military point of view, the folding-boat may be used for crossing streams or reconnoitering, or it may be for use as a bridge ponton. Such boats are also used by sportsmen who travel a distance to meet aquatic game, finny or feathered, on coast, lake, or river.

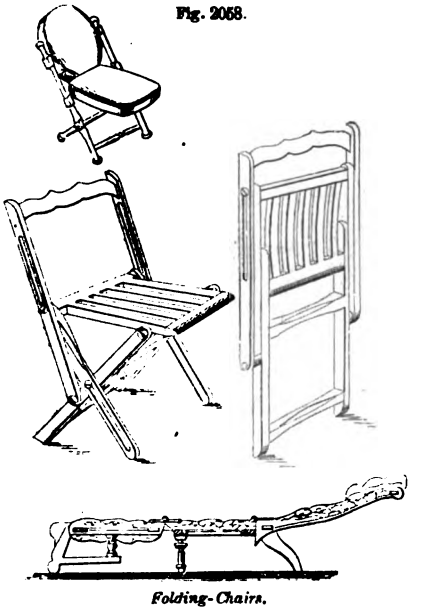
The illustrations show several kinds, and a score more might be readily given would room permit. The upper one is a davit-boat, which lies compactly against the ship's side until the toggle-frame is extended, and the elastic skin distended thereby. It is then swung clear and lowered.

Next are two views, in the extended and collapsed forms respectively, of a boat whose sides are hinged to the keel, and whose stem and stern may be laid over towards the midship section in a similar manner, though this does not appear in the engraving. *c c* are bags of cork which are pendent in the collapsed form, but are caught up against the gunwale when the boat is ready for duty.

The lower figure has a frame which may be folded up to the length of the ribs, and a width equal to the thickness of the ribs when laid up close together. In use, a skin of sufficiently tough waterproof material is stretched over the extended frame. See also LIFE-BOAT.

Fold'ing-chair. A chair which is collapsible for carriage or stowage. One of the examples is a

Fig. 2058.



Folding-Chairs.

library-chair. Another is a camp-chair in two positions. The lower one is in its most prolonged form, and is a lounge.

Fold'ing-door. A pair of doors hung from opposite sides of the aperture, and meeting midway of the passage.

Fold'ing-ma-chine'. 1. A machine for folding printed sheets for books: or newspapers for mailing.

The book-folding machine illustrated is for octavo work, sixteen pages on a sheet, eight pages on a side. The sheet is placed on the table, so that two register-points pass through holes in the sheet previously made on the printing-press. The folder *b* comes down upon the folding edge, the pins give way, and the sheet passes, doubled-edge first, between a pair of rollers which compress it; tapes deliver it to a second table beneath, where a second and a third folder act upon it in turn, and it is delivered into a trough.

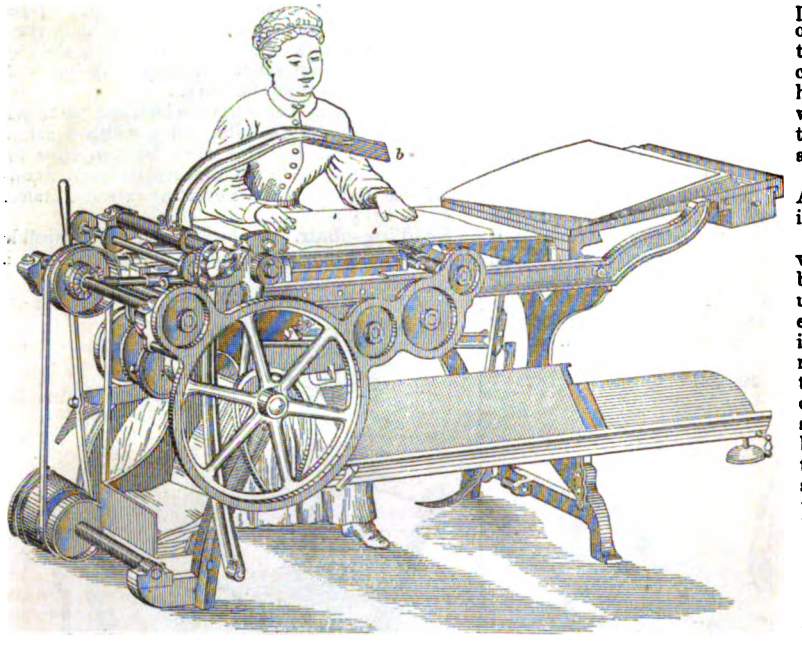
With 12mo work, imposed in two parts of sixteen and eight pages respectively, the machine cuts

Digitized by Google

them apart, folds the larger part like an octavo, the smaller folds but once, and is then *inset* into the octavo portion which forms the *outset*.

The two-sheet folder and paster, for large 24-page periodicals, folds one sheet of sixteen pages, 30½ × 45½ inches, and another of eight pages, 22¾ × 30½ inches, insetting the eight pages within the sixteen, and pasting and trimming all, delivering a complete copy of twenty-four pages ready to read. It will fold eight pages alone, sixteen pages alone, with or without pasting, or trimming; or will fold, paste, and trim the sixteen pages, and fold, paste, and trim the eight pages, insetting same without pasting in the inset.

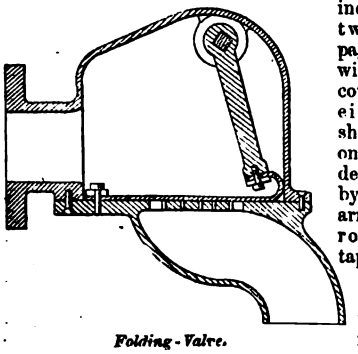
Fig. 2059.



Chambers's 8vo Book-Folding Machine.

Machines of this general character are also made for folding, pasting, and trimming; or for folding, pasting, trimming all round, and putting on a cover of different colored paper. Rev. H. W. Beecher's weekly journal, the "Christian Union," is folded, inset, and covered in this manner. This paper uses a single large sheet of 43 × 47 inches, making twenty-four pages, and, with the added cover, twenty-eight. The sheet is printed on a four-cylinder press, and, by an ingenious arrangement of rollers and tapes, fed mechanically from the impression-cylinders into four folding-machines, an attendant being at each machine to secure accurate pointing. This economy of time in feeding, etc., makes easily possible the printing, folding, pasting, trimming, and mailing (by Dick's system) of nearly 150,000 papers every week, within two and a half working days.

Fig. 2060.



Folding-Valve.

2. (*Metal.*) One which bends pans and tin-ware to form. Some are rollers, others presses, and yet others act like the envelope-machine, having hinged leaves which press up the sides against a former.

Fold'ing-net. A bird-net shuting upon its prey.

Fold'ing-valve. A flexible flap which lies upon the perforated plate forming its seat, and rolls or unrolls thereupon to open or close the passage-way. The band is connected to an arm on a shaft which passes through a stuffing-box to the outside of the case.

Fo'li-at'ed-arch. (*Architecture.*) One having a number of lobes or leaves. See ARCH.

Fo'li-at'ed-joint. (*Carpentry.*) A rabbeted joint, where one part overlies another.

Fo'lio. 1. The running number of the pages of a book. The *even* folios are on the left-hand pages, the *odd* upon the right. The folios of prefatory matter are frequently in lower-case Roman numerals.

2. A book whose sheets are folded but once, four pages to the sheet.

Fo'lio-post. A flat writing-paper, usually 17 × 24 inches.

Fol'low-board. (*Founding.*) A board beneath the pattern, and on which it lies while the loam is being rammed. See FLASK.

Fol'low-er. 1. A portion of a machine, usually sliding in guides, and moved by another portion; as the reciprocating punch-stock in a fly-press, which is moved by the screw to which it is swiveled. It is analogous to the platen of many presses.

2. The cover or *plug* of a stuffing-box, which rests upon and compresses the packing. A *gland*.

Fol'low-er-wheel. The *driven* wheel, as distinguished from the *driver*, or the wheel which impels.

Fon'dus. A style of calico-printing or paper-hanging in which the colors are in bands and blend into each other.

Font; Fount. (*Printing.*) An assortment of type of one size, of a given weight, containing large and small capitals, small letters, points, accents, figures, spaces, quads, etc. The weights of fonts vary according to the business requirements of the printer. While a 500-pound book-font was considered a good weight during the last century, some American houses-

Digitized by Google

now keep a font of from 20,000 to 30,000 pounds in use.

The following table gives an English bill of Pica, weight 800 pounds, italic one tenth.

Em-quadrats	2,500
En-quadrats	5,000

Large Quadrats.

2-em, 3-em, 4-em } 80 pounds.

Metal Rules.

1-em, 2-em, 3-em.

For indexes and similar matter, the above would be deficient in capitals.

For setting up French or Italian matter, it would be deficient in accented vowels.

It comprises, —

Capitals; as, A, B, etc.

Small capitals; as, A, B, etc.

Lower case; as a, b, etc.

Figures and fractions; as, 1, 2, 3; ½, ⅓, 1/10, etc.

Points, — , ; : . ? ! - ' ( ) [ ] * † ‡ § ‖ ¶ — ~~

Spaces. Quads.

Accents; as, á, à, â, ä, ā, ă.

The above bill does not include, —

Superior letters in caps or lower case; as, A^A, B^B, etc.; A^a, B^e, C^d, etc.; a^a, b^c, etc.; c^e, d^b, h^d, etc.

Inferior letters in caps or lower case; as, A_C, C_B, etc.; A_a, B_a, B_b, etc.; a_B, c_E, etc.; a_a, b_a, c_b, etc.

Superior figures in Arabic or Roman; as B^1, C^2, D^3, etc.; a^i, b^{ii}, c^{vi}, etc.

Inferior figures in Arabic or Roman; as, A_1, B_2, C_3, etc.; a_i, b_{iv}, c_v, etc.

Prime letters; A′, B″, C‴; a′, b″, c‴, etc.

Arithmetical signs; such as +, ×, −, ÷, :, ::, =, √.

Notation of arc: °(degrees), ′(minutes), ″(seconds).

Of quantity: ℔, ℥, ℨ, ℈, ℔.

Commercial: $, ¢, ℔, %, @, ℀, £.

Besides these, there are hundreds of arbitrary signs, which are found in the most perfect fonts, and used in astronomical, classic, commercial, musical, chemical, botanical, arithmetical, and mathematical dissertations.

For these, see an excellent digest on pp. 1692–96 of Webster's Unabridged Dictionary, edition of 1867.

Almost every science has symbols of its own. Algebra has one set, chemistry another. For a dictionary which attempts to represent the minute shades of pronunciation a great number are required. Thus in Webster or Worcester, what with letters with dots above and dots below, lines above, below, and across, there are probably a hundred additional characters. Some foreign languages have a very complicated alphabet. The Greek, with its "accents" and "breathings," requires about 200. Formerly there were so many logotypes and abbreviations as to require 750 sorts. The Oriental alphabets are complex. The Hebrew, with the Masoretic points, requires about 300 sorts, many differing only by a point, stroke, or angle. The Arabic has quite as many. In Robinson's Hebrew Lexicon, eight or ten Oriental languages appear, and required 3,000 sorts distributed through at least forty cases.

Fools'cap. A size of folded writing-paper named from the water-mark of a "foolscap and bell" which formerly ornamented (?) it.

In England, it has four grades of size and weight.

	Size.	Weight.
Sheet and a half foolscap,	25½ × 13½ inch.	22 pounds.
Sheet and third "	22 × 13½ "	20 "
Extra thick "	16½ × 13½ "	18 "
Ordinary "	16½ × 13½ "	15 "

The American average may be stated at 16 × 12½.

Foot. 1. (*Music.*) The lower end of an organ-pipe, which conducts the wind to the *reed* or *lip*, which gives the vibration to the air and causes the sound.

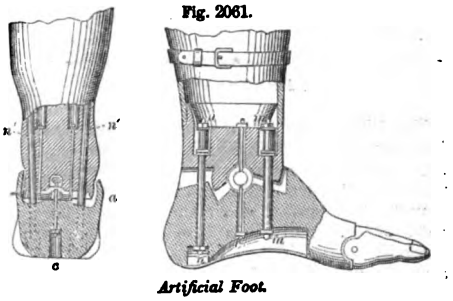
2. (*Nautical.*) The lower edge of a sail.

3. (*Machine.*) A flange at the lower end of a leg to give a wider basis of support.

4. A third of a yard. See UNIT.

Foot, Ar'ti-fi'cial. A prosthetic contrivance which copies the articulations of the natural foot. In the best efforts in this line, the ankle-joint is a

Fig. 2061.



Artificial Foot.

bolt which is transverse with the foot, a certain degree of lateral flexure in a vertical plane being also permitted, as seen by the interval shown in the left-hand figure opposite to *a*. The other figure also shows a certain liberty of forward and backward rocking motion. The middle rod *c* is a permanent tension-rod, and the rods *m n n′* have a certain amount of elasticity by means of rubber nuts, so as to allow flexure of the joint.

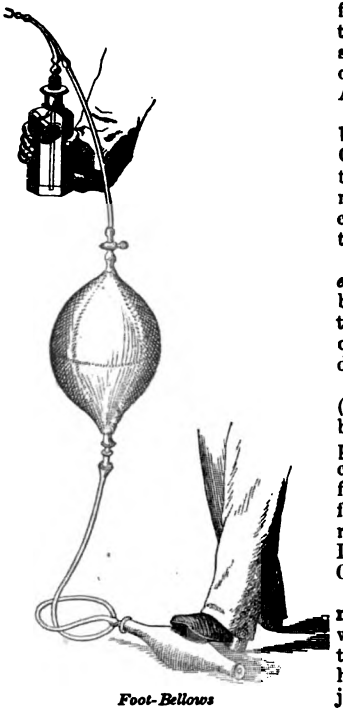
Foot-bellows. A form of bellows with a collapsible bag, or an ordinary bellows arranged to be worked by treadle. It is shown (Fig. 2062) as adapted to a spray apparatus.

Foot-board. 1. A treadle.

2. A board at the foot of a bed; a board for the feet on the driving-box of a coach.

Digitized by Google

Fig. 2062.



Foot-Bellows

8. The platform on which the driver and stoker of a locomotive stand. A *foot-plate*.

Foot-bridge. 1. One for pedestrians over a railway or crowded city thoroughfare.

2. (*Machinery.*) A curved bar supporting the *foot* or *toe* of a mill spindle. See STEP.

Foot-guard. (*Menage.*) A boot or pad to prevent the cutting of the feet by interfering or overreaching. See LEG AND FOOT GUARD.

Foot-ham'mer. One worked by a treadle. The hammer is adjustably pivoted to the upright, and has toggle connection with the treadle, whose depression causes the descent of the hammer upon the anvil. The hammer is raised by a spring.

Fig. 2063.

Foot-Bridge

Foot'ing. 1. (*Hydraulic Engineering.*) The lower portion of the slope of a sea embankment. It should have a base of five feet to one foot perpendicular and be protected by gravel. The portion above the footing is the *outburst bank*, and has a base of two to one perpendicular. The crowning portion is the *swash-bank*, which has a base of two to one perpendicular, the level on top being four or five feet. In Holland, where the summit is used for roads, this width is much increased.

2. (*Masonry.*) The spreading courses at the bottom of a wall, to give a greater basis of support.

Foot-i'ron. A carriage-step.

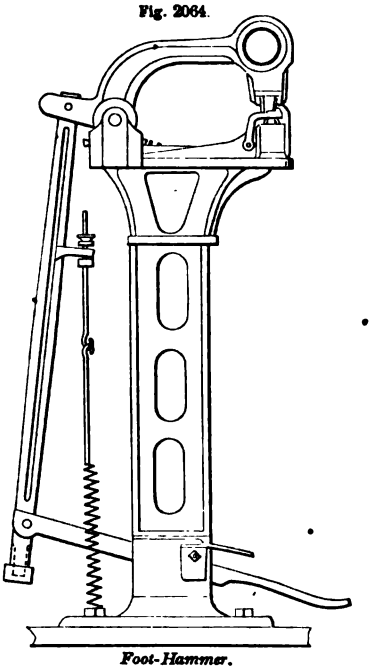
Foot-key. (*Music.*) An organ pedal.

Foot-lathe. A lathe driven by the foot on a treadle, connected to a crank on an axle beneath the bench. A driving-wheel on the axle is connected by a band to a cone-wheel on the mandrel of the head-stock.

Foot-lev'el. A form of level used by gunners in giving any proposed angle of elevation to a piece of ordnance. See LEVEL.

Foot-light. A light on the front of a stage.

Fig. 2064.



Foot-Hammer.

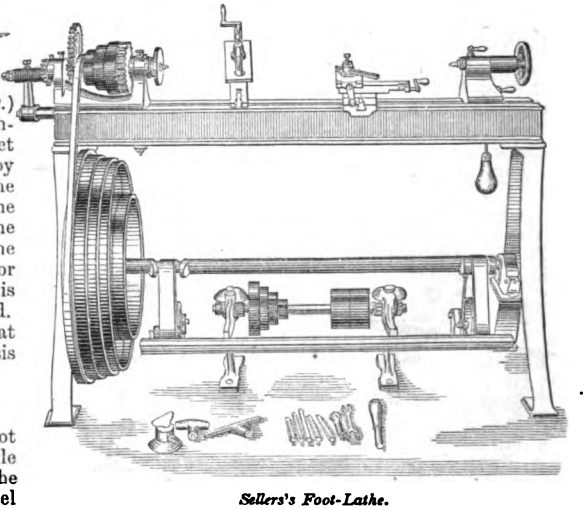
Foot-pace. A *dais*, or raised floor.

Foot-pad. (*Menage.*) *a.* A piece of elastic substance, say rubber, to cover the sole of a horse's foot and prevent balling.

b. An anklet or ridge-piece on the corona to prevent cutting of one foot by the other in traveling.

Foot-plate. The platform for the driver and fireman of a locomotive.

Fig. 2065.



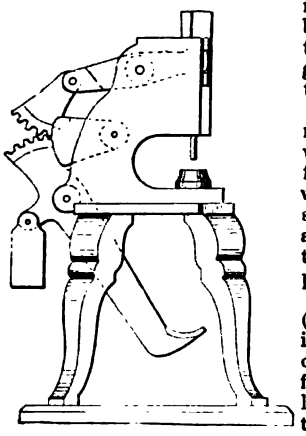
Sellers's Foot-Lathe.

Foot-pound. A term in mechanics; the unit of energy, 1 pound avoirdupois raised 1 foot. See UNIT.

Foot-press. A form of standing press in which the upper die or follower is depressed by a treadle.

Digitized by Google

Fig 2066.



Foot-Press.

In the example, the motion is obtained by the mashing of two segmental cam-gears forming a toggle.

Foot-rail. A railroad-rail having wide-spreading foot flanges, a vertical web, and a bulb-shaped head. Such a rail may be spiked to the sleepers, dispensing with chairs.

Foot-rest. (*Menage.*) A stake in a shoeing shop on which a horse's foot is rested to relieve the shoer from the labor of supporting it.

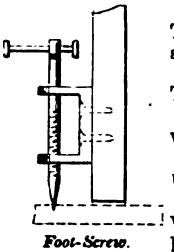
Foot-rope. (*Nautical.*) *a.* A rope stretched beneath a yard, upon which the seamen stand in reefing or furling sails.

b. A rope at the foot of a rail.

Foots. Sedimentary matter; the remainder or refuse of decantation or distillation.

Foot-screw. A supporting foot, for giving a machine or table a level standing on an uneven floor.

Fig. 2067.



Foot-Screw.

Foot-stalk. (*Machinery.*) The lower portion of a mill spindle; it rests in a *step*.

Foot-stall. 1. (*Architecture.*) The plinth or base of a pillar.

2. (*Menage.*) The stirrup of a woman's saddle.

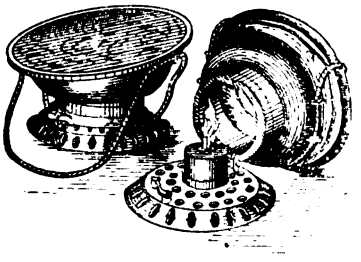
Foot-step. An inclined plane under a hand printing-press.

Foot-stick. (*Printing.*) A wedge-shaped piece of furniture placed against the foot of the page. The *quoins* are driven in between the *foot-stick* and the *chase* in locking up the *form*.

Foot'stool. A low stool for the feet.

Foot-stove. A foot-warmer; usually heated by a lamp.

Fig. 2068



Foot-Stove.

Foot-valve. (*Steam-engine.*) The lower valve between the air-pump and condenser. See AIR-PUMP, p. 53.

Foot-vise. A vise whose jaws are brought together by means of a strap passing through the two and operated by a treadle. It has not a very powerful grasp, but from the facility with which the jaws are opened or closed is useful in operating on objects which do not require to be held very firmly.

Foot-wal'ing. (*Shipbuilding.*) The inner skin of a ship between the *deck-beams* and the *limber-strakes* on each side of the *keelson*. Also called the *ceiling*.

Foot-warm'er. A heated stool for the feet. A chafing-dish. A *foot-stove*.

A hot-water bottle shaped to fit against the soles of the feet of a person lying in bed.

For'ceps. A tool applied to grasping, and consisting of two portions pivoted together, the ends forming respectively handles and jaws.

Shears, scissors, pincers, pliers, tongs, calipers, nippers, punches, and some other tools, agree in the pivoting of duplex parts, but they differ in some peculiarity of the jaws or in their special application for cutting or grasping. See JAW-TOOLS.

Forceps for teeth, uvula, arteries, esophagus, etc., were found in a house in Pompeii in 1819. They were of iron and copper.

Specifically: in obstetrics, an instrument having a pair of curved blades for grasping the head of the fetus and assisting delivery.

See under the following heads: —

Trachea-forceps.
Uvula-forceps.

Force-pump. 1. A pump which delivers the water under pressure, so as to eject it forcibly or deliver it at an elevation. The term is used in contradistinction to a *lift-pump*, in which the water is lifted, and simply *runs* out of the spout.

The *single-acting* force-pump is that in which the *lift* and *delivery* are alternate. The *double-acting* is that in which the passages are duplicated, so that a *lift* and *delivery* are obtained by each motion of the plunger: the pump has a distinct water-way both above and below the piston, so as both to draw and force water at each stroke, and thus cause a continuous stream, which is rendered more uniform by an air-chamber.

The invention of the force-pump is ascribed to Ctesibus of Alexandria, who is assumed to have been the tutor of Hero, who wrote so largely on hydraulics. It was also described by Vitruvius.

In 1582, Peter Morice, a Dutchman, erected a pumping-engine at London Bridge, where it or its successors remained till 1821. The power was a current-wheel turned by the flow and ebb, and first placed *near* the bridge, then *under* the northern arch; afterwards three wheels were added under the third arch; Smeaton added another under the fifth arch, and afterwards a steam-engine to assist at low-water and neap tides. See CURRENT-WHEEL.

The water-wheel of Morice worked sixteen force-pumps, each seven inches in diameter, the pistons having a stroke of thirty inches, throwing 216 gallons per minute into a cistern elevated 120 feet, whence the dwellings in the vicinity were supplied with water by leaden pipes.

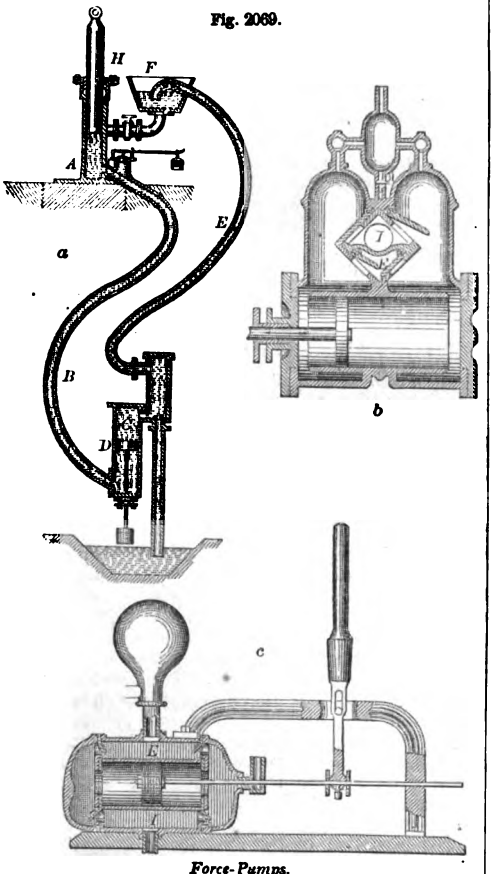
In 1731 the works are again described. Sixty-

Digitized by Google

eight pumps were then at work, throwing 2,052 gallons per minute. The cylinders were of cast-iron, 4 feet 9 inches long, 7 inches bore, and discharged by a stand-pipe into a cistern elevated 120 feet.

The Verpilleux pump (*a*) is a single-acting force-pump in which a column of water communicates between the working cylinder and the water level. When the plunger *H* rises, water ascends and passes through *C* into *B* and upward into *A*; owing to the pressure of air upon the surface of the water in the cistern, supplemented for hights above, say 30 feet, by the weight of the loaded piston *D*. When the

Fig. 2069.



Force-Pumps.

plunger *H* descends, the column of water in *B* acts upon the piston *D*, and raises water in *E* to the reception cistern *F* above.

b c are two forms of double-acting force-pumps, in each of which *I* is the induction and *E* the eduction.

2. The boiler-supply pump connected to the piston-rod of the cylinder of a locomotive.

For'cer. A small pump worked by hand; used in sinking pits, draining cellars, etc.

Forc'ing-pit. A sunken hot-bed.

Fore. (*Nautical.*) The term expressive of the forward portion of a vessel, or the appurtenances of the said forward portion. The term is used in contradistinction to *aft*.

Fore-and-aft Sail. (*Nautical.*) A sail whose middle position is fore-and-aft; one which is attached to a spar or stay in the midship line of the vessel, and not to a yard, which is athwart ship.

It may be three-cornered, as a *stay-sail* or *jib*, or four-cornered, as a *try-sail*, *spanker*, etc.

Of the latter, —

The upper, after corner is the *peak*.

The upper, forward corner, the *throat* or *neck*.

The lower, after corner, the *clew*.

The lower, forward corner, the *tack*.

The *clew* is hauled aft by a rope called the *sheet*.

The *tack* is hauled forward by a rope also called the *tack*.

In a fore-and-aft sail, —

The *head* is the upper edge if the sail be four-cornered, or the upper corner if the sail be three-cornered.

The *foot* is the lower edge.

The foremost edge is called the *luff* or *weather-leech*.

The aftermost edge is called the *lee-leech*, or the *leech*.

Schooners, smacks, and cutters are fore-and-aft rigged. The *spankers*, *drivers*, *jibs*, *try-sails*, and *stay-sails* of other vessels are also fore-and-aft.

Fore-bay. (*Hydraulics.*) A reservoir or conductor between a mill-race and a water-wheel. The discharging-end of a head or mill-race. The term is the equivalent of *penchute* or *penstock*, but is used especially in regard to water-wheels, which receive and discharge water at their peripheries, such as the under-shot, over-shot, breast, and flutter-wheels.

Fore-beam. (*Weaving.*) The breast-beam of a loom.

Fore-bow. (*Menage.*) The pommel or horn of a saddle.

Fore-car'riage. (*Vehicle.*) The forward part of the running gear of a four-wheeled vehicle. The fore-wheels, axle, and hounds; with or without the *pole* and the *perch*.

Fore'cas-tle. (*Shipbuilding.*) *a.* In flush-decks; a part of the upper deck forward of the after fore-shroud.

b. A short upper deck forward. Formerly raised like a castle to command the enemy's decks. A top-gallant forecastle.

c. A forward part of the space below decks in merchant-ships, for the seamen.

Fore-edge. The front edge of a book or a folded sheet; in contradistinction to the *back*, which is folded, and holds the stitching.

Fore-foot. (*Shipbuilding.*) The forward end of a vessel's keel on which the stem-post is stepped.

Fore-gang'er. (*Nautical.*) A short rope grafted on to the harpoon, and to which the rope is bent.

Fore-ham'mer. A sledge-hammer, working alternately or in time with the hand-hammer.

Fore-hook. (*Shipbuilding.*) A strengthening piece in the stem, binding the bows together. A *breast-hook*.

Fo'rel. (*Bookbinding.*) A kind of parchment for book-covers.

Fore'land. 1. (*Hydraulic Engineering.*) That portion of the natural shore on the outside of the embankment which, standing several feet above low-water mark, and having a considerable breadth, acts as an advanced guard to the embankment to receive the shock of the waves and deaden their force upon the bank.

2. (*Fortification.*) A space between a fortified wall and the moat.

Fore-lock. A cutter or split pin in the slot of a bolt to prevent retraction. A *linch-pin*. A *pin* fastening the cap-square of a gun. A *key*.

Fore-lock Bolt. One retained by a *key*, *gib*, or

Digitized by Google

cotter passing through a slot of the shank. See KEY; COTTER.

Fore-lock Hook. (*Rope-making*) A winch or *whirl* in the *tackle-block* by which a bunch of three yarns is twisted into a *strand*.

Fore'mast. (*Nautical.*) The one nearest to the bow, in vessels carrying more than one mast, except in the case of a *ketch*, whose forward mast is the *main*, as being the longer of the two, the after-mast being the mizzen.

Fore-part Iron. An edge rubber or burnisher for boot and shoe soles.

Fore-piece. (*Saddlery.*) The flap attached to the fore-part of a side-saddle, to guard the rider's dress.

Fore-plane. (*Joinery.*) Intermediate in length and application between a *jack*-plane and a *smoothing*-plane.

Fore-rake. (*Shipbuilding.*) So much of the forward part of a vessel as overhangs the keel.

Fore-run'ner. (*Nautical.*) A piece of red bunting on a log-line at a certain distance, say twelve or fifteen fathoms, from the log-chip; the fathoms begin to count at the fore-runner, and the non-counting portion is called the *stray-line*. The latter is an allowance to allow the log to be out of the ship's dead-water. See LOG.

Fore-shore. (*Hydraulic Engineering.*) *a.* A bank a little distance from a sea-wall to break the force of the surf.

b. The seaward projecting, slightly inclined portion of a breakwater.

Fore-shot. The first portion that comes over in distillation of low wines. It is a milky liquid and abounds in fusel oil.

Fore-sight. 1. A sight *forward* at the leveling-staff or through the sights of the circumferentor.

2. The muzzle-sight of a gun.

Fore-staff. (*Optics.*) An instrument formerly used at sea for taking the altitude of heavenly bodies, and also known as a *cross-staff*. The observer faces the object, the position being the reverse of that assumed in using the *back-staff* for a similar purpose. The fore-staff has a straight, square staff graduated like a line of tangents, and four *crosses* or vanes which slide thereon. The first and shortest of these vanes is called the *ten*-cross, and belongs to that side of the instrument whereon the divisions begin at 3° and end at 10°. The next longer vane, called the *thirty*-cross, belongs to the side of the staff graduated from 10° to 30°. The *sixty*-cross belongs to the side graduated from 20° to 60°. The *ninety*-cross belongs to the side of the staff graduated from 30° to 90°.

Fore-star'ling. An ice-breaker in advance of the *starling* of a bridge.

Fore-wale. (*Saddlery.*) The smaller roll of a horse-collar.

Forge. 1. A blacksmith's open fire, where iron is heated by the aid of a blast. The illustration shows a portable form, in which the bellows is worked by a treadle, the air-pipe passing upward and through a tuyere into the coal-box *a*, which is shown empty. *b* is the slake-trough.

2. A building in which blacksmith's forges or furnaces are arranged. When on a large scale, furnaces, cranes, and steam-hammers are necessary adjuncts. A *smithy*.

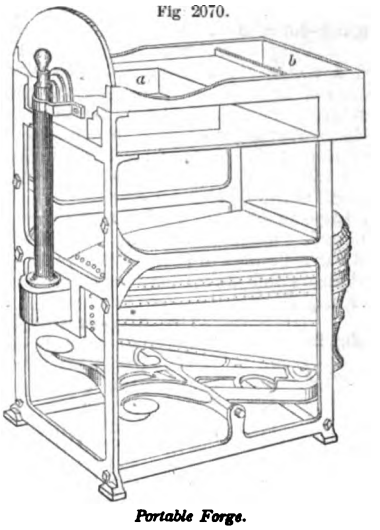
3. A place where iron is puddled and shingled.

4. A field-forge in military service. See BATTERY-FORGE.

The subject of *forging* is incidentally considered under CANNON, ARMOR-PLATING, and elsewhere, and the appliances under ANVIL, HAMMER, etc. See HAMMER; also list under BLACKSMITH'S TOOLS, etc.

Considering how lately it has been deemed possible to forge very large masses of iron, and how all

Fig 2070.



Portable Forge.

the best modern appliances of furnaces, cranes, and steam-hammers are engaged in the production of heavy cannon, screw and paddle shafts of steamships, anchors, etc., we may well be surprised at the existence within the cincture of the ancient Mosque of the Kutub, near Delhi, of a wrought-iron pillar of a size which would be deemed a first-class forging in the most capable works of Europe or America. The pillar is, however, more than 1,000 years old, and may be as much as 1,500. It is believed that the ornamental capital was chipped from the solid. Digging has shown that the greater portion of the length is buried in the ground. It has about midlength an inscription in Sanscrit, in a character which has been assigned to the period A. D. 300 to 400. It has been described at length by Mallet in the "Engineer." The present writer concludes that it is a casting from iron smelted by a process allied to the Catalan, — the ordinary smelting process of Asia and Africa, in fact, — from a magnetic or hematite ore by charcoal. Such an iron may be worked to some extent by the hammer.

Fig. 2071.

Iron Pillar of Delhi.

The iron pillar of Delhi has the following dimensions: —

Hight above ground	22 feet.
Depth beneath ground, so far as is known by digging	26 "
Estimated hight	60 "
Hight of capital	3½ "
Upper diameter of shaft	12.05 inch.
Lower diameter of shaft	16.4 "
Weight (calculated)	38,080 lbs.

Forge-rolls. The name conferred upon the train of rolls by which the slab or bloom is converted into puddled bars.

Digitized by Google

They consist of two pairs, the *roughing-down* rolls and *finishing* rolls.

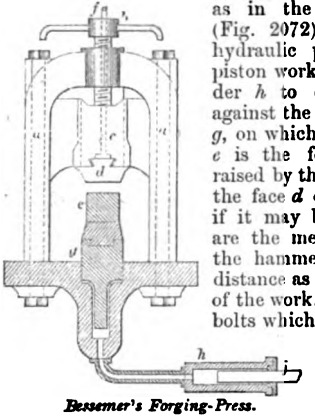
For'gette. (*Glove-making.*) Fr., *fourgette.* The piece put between the fingers of a glove, and to which the front and back parts of the fingers are sewed.

Forg'ing-ham'mer. A hammer used by gold-beaters. It weighs three pounds, has a head at one end and a wedge at the other, the face having a square area of 1½ inches on the side. Its handle is 6 inches long. It is the first hammer in the series, and reduces the ingot of gold to one sixth of an inch. The anvil is a mass of steel four inches long and three broad. The *laminating-machine* is often used instead of the *forging-hammer.*

Forg'ing-ma-chine'. A machine having a number of plunging mandrels and stakes between which a heated bar is pressed to form. The opposing faces of the plungers and stakes may be merely hammer-faced, or may be shaped to act as swages.

Forg'ing-press. One for forging by means of pressure, as in the Bessemer press (Fig. 2072), which acts by hydraulic pressure. *j* is a piston working in the cylinder *h* to drive the water against the base of the piston *g*, on which is the anvil face. *c* is the forging which is raised by the piston *g* against the face *d* of the hammer *c*, if it may be so called; *f b* are the means for lowering the hammer *c d* to such a distance as may suit the size of the work. *a a* are through-bolts which sustain the pressure.

Fig. 2072.



Bessemer's Forging-Press.

Fork. An implement with prongs for lifting, digging, carrying, or throwing. Its uses may be principally included under the heads of *agricultural* and *husbandry* uses and *domestic* uses.

Of the former are: —

Dung or *manure* forks.
Horse hay-forks.
Digging-forks.
Grain-forks.
Hay-forks.
Pitch-forks.

Of the domestic are: —

Culinary or *flesh* forks. *Table*-forks.

1. The fork of the husbandman is shown on the Egyptian tombs, and referred to in the Book of Judges, 1093 B. C.: "Yet they had a file for the mattocks, and for the colters, and for the forks."

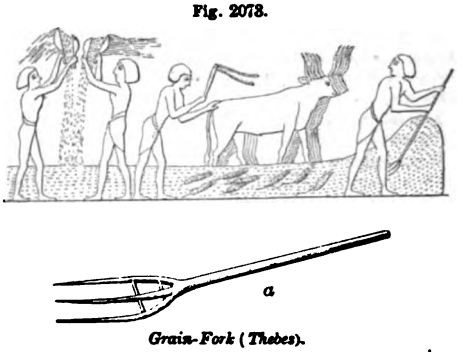
The pitch-fork is used for grain in the straw or sheaf, hay, and manure. It has from two to four teeth, according to its purpose. The four-pronged is used for manure, the others for straw, sheaves, or hay.

Another form of grain-fork (*a*) is of wood, the operative end being slit into three prongs, which are held apart by wedges and braced by rods.

It is used in delivering the gavel of grain from the platform of the reaping-machine, and is preferred for the reason that its tines do not injure the platform, or offer so much danger to the person or the machine as do sharp iron tines.

In the scenes where the thrashing of grain is represented on the tombs of Egypt, we see several instances of the three-pronged fork. It appears to be of wood, the end split into three tines, which are

Fig. 2073.



Grain-Fork (Thebes).

held apart in some way, perhaps, as with us, by wedges.

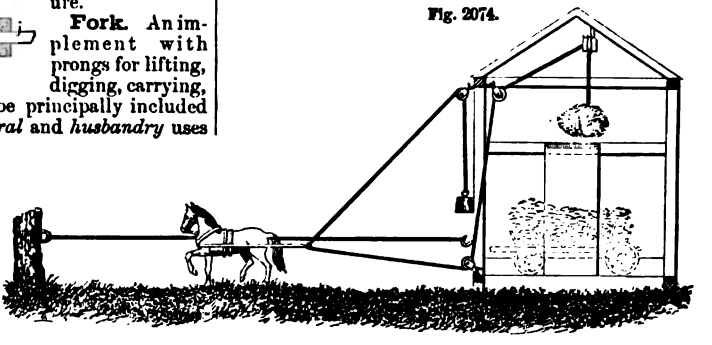
The digging-fork has four flat steel tines, and is a very effective tool.

The pitch-fork has two or three long, round tines, and is used for pitching hay or sheaves. The barley-fork is a peculiar fork having a guard on the head, and used for pitching gavels of short grain without binding.

The horse hay-fork is designed to obviate the great labor of pitching hay from the wagon into the mow, or from the wagon or the ground into the stack. They are of four kinds: —

1. The *harpoon*-fork.
2. The *jointed*-fork.

Fig. 2074.



Operating Horse Hay-Forks.

3. The *tongs*-fork.
4. The *corkscrew*-fork.

Fig. 2074 gives a general idea of the mode of operating the fork. A rope passes from the single-tree of the horse over three pulleys to the fork, which is thrust into the load. When the horse starts up, the load is lifted, and when it has reached the desired hight a trigger is pulled and the load dropped. The horse is backed, allowing the fork to descend, assisted by the weight which takes up the slack of the fall.

1. The *harpoon-fork* is thrust endwise into the hay, the tines being sheathed; then, by the motion of a lever, the tine or tines are exposed so as to catch the hay and elevate it when the fork is lifted. On reaching the place where the forkful is to be deposited, the catch which holds the tines in their ex-

Digitized by Google

tended position is dropped by drawing on a trigger; the tines becoming sheathed by the pressure upon them of the hay, the latter slips off. Two forms of this are shown, but twenty-eight are before the writer while making this notice. Fig. 2075 has a tube from which protrude two prongs *F F*, which are thrust out into the hay after the stem has been driven in to the required depth. When lifted, the load rests on the prongs, and when a trigger on the stem is pulled by the cord *g*, the prongs retreat; the tube falls until it catches on the cross-piece of the stem *D*. In Fig. 2076 the parts *E* and *F* form the entering portion and maintain a general longitudinal direction while the fork is thrust into the hay, and are vibrated outwardly to hold the hay by the pivoted rod, which is actuated by a lever and auxiliary rope, to drop the load when it has arrived over the desired spot.

2. The *single-jointed* fork is one in which the tines are hinged to the stock, so as to assume a position in which the hay will be sustained, but capable of being dropped from this position so as to allow the hay to slip off. The *modus operandi* is this:

Fig. 2075.

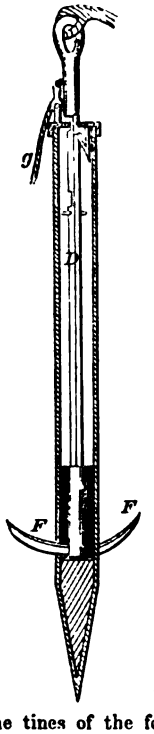


Fig. 2076.

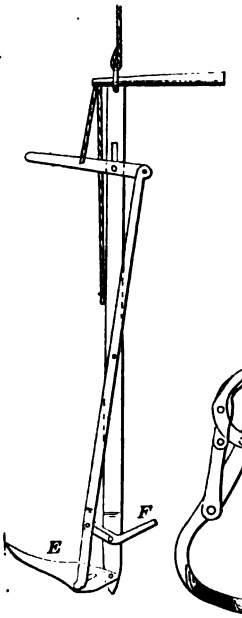

Harpoon-Forks.

The tines of the fork in its effective position are thrust into the hay, and the fork with its load is then elevated. On reaching the place where the load is to be deposited, a trigger is pulled, releasing the tines; the weight of the hay causes them to drop, and the load slips off.

Of fifteen kinds at hand, two may be selected as representative. In Fig. 2077, the tines are on a head attached to the stock *C* and hinged to the bail *D*. *F* is a hinged brace, which thrusts against a stud in a slot of the stock *C*, to hold the tines in their holding position. The tines are tripped by the rope and trigger *i*, which pushes the brace *F* off the detent and allows the head and stock to rotate on the bail.

Fig. 2078 has its tines *a* hinged at midlength, and tripped by lifting the trigger *e* on the end of the rope *f*.

3. The *tongs*, or *grabbing-fork*, has two hands, so to speak, which clasp upon the bunch of hay, and are locked in their closed position while the hay is being lifted. When arrived at the place to drop the hay, a rope attached to a trigger is pulled, the two heads of the fork are unlocked, and the weight of the hay presses them open, the hay falling out. The two forms shown are held closed by a straight toggle, and opened when the toggle is bent by a pull on the rope. In Fig. 2079 the fork is swung from one prong, and in Fig. 2080 from both prongs.

Fig. 2077

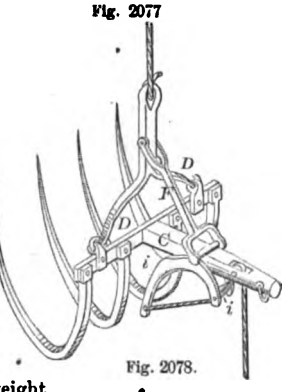

Fig. 2078.

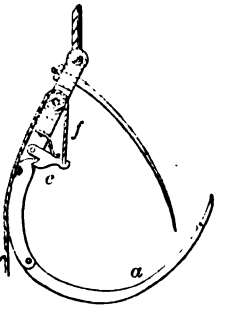

Jointed Forks.

4. The *corkscrew-fork* is screwed down into the hay, turning in its handle or stock; a latch holds it in position while the hay is lifted. A trigger then releases the catch, and the tine being freed is rotated by the weight of the hay which slips therefrom.

Fig. 2079.

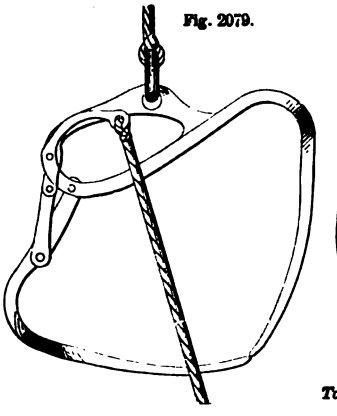

Fig 2080.

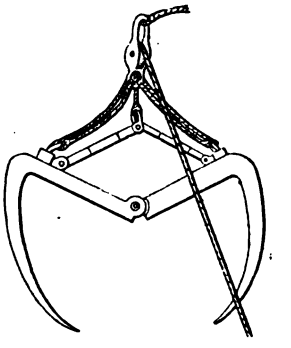

Tongs-Forks.

As the vertical tines descend into the bunch of hay, the spiral tines are rotated and then locked. The load being elevated, the cord is pulled, disengaging the detent and revolving the spiral tines to discharge the load.

2. Forks for culinary purposes were common in ancient times, *vide* the observances of the Hebrew priests, who dipped their forks into the seething-pot and lifted the meat thence. The table-fork is a modern invention, deriving its name from the Italian *forca*.

The Greeks and Romans had also flesh-forks or rakes to lift meat from the pot, but they had no table-forks. The carver, *carptor*, had a knife for carving, and the guests furnished their own. The meat was grasped by the finger and thumb of the

Digitized by Google

Fig. 2081.

Corkscrew Hay-Fork.

left hand, and a piece excised. The New Testament, Homer, and Ovid mention the putting of the hands in the dish.

The "dipping in the dish" refers to making a scoop of a piece of bread and dipping out the soup or gravy. To give a "sop" thus prepared to a friend at table was a delicate attention. Judas received his and "went out." The mark of kindness was too much even for his selfish heart.

The Chinese use chop-sticks instead of forks.

Bronze forks were used by the Egyptian priests in presenting offerings to the gods. Two of them exhumed at Sakkarah are in the Abbott collection.

A fork is mentioned in the accounts of Edward I., and is supposed to have been brought from the East by a returning crusader. Voltaire says that they were used by the Lombards in the fourteenth century; and Martius states that they were common in Italy in the fifteenth century.

Table-forks are heard of in Italy from 1458 to 1490. An Italian at the court of Matthias Corvinas, king of Hungury, notices the lack of the fork in the table furniture of the king. A century after, they were not known in France or Sweden.

Coryat, in his "Crudities," 1611, says: "I observed a custom in all those Italian cities and towns through which I passed, that is not vsed in any other country that I saw in my traules, neither doe I think that any other nation in Christendome doth vse it, but only Italy. The Italians and also most strangers that are commorant in Italy, doe alwaies at their meales vse a little fork when they cut their meat."

Fyne Moryson's "Itinerary," in the reign of Elizabeth, refers to their use in Venice.

Heylin in his "Cosmograph," 1662, says: "The use of silver forks, which is by some of our spruce gallants taken up of late, came from China into Italy, and thence into England."

Table-forks have long been in use in Feejee. At a time when all Northern Europe was destitute of the article, these remarkable savages, the most cruel and ingenious of all the natives of Polynesia, used forks in conveying to their mouths morsels of *puaka-balava*, long-pig, as they called cooked man.

Table-forks of the best quality are forged from the end of a rod of cast-steel, about three eighths square. The tang, shoulder, and shank are roughly formed and cut off, the prongs being a flat portion which is stamped out by a swage drop. The film between the tines is cleaned away by the file. These processes are followed by hardening, tempering, grinding, and hafting.

Fork-beam. (*Shipbuilding.*) A half-beam to support a deck where hatchways occur.

Fork-chuck. (*Turning.*) A piece of steel projecting from the live spindle and carrying the front center and a pair of joints which enter the wood and rotate it.

Fork-head. The double head of a rod which divides in order to form a connection by means of a pin.

Fork'staff-plane. (*Joinery.*) A joiner's plane for working convex cylindrical surfaces.

Fork-wrench. A spanner with two jaws which embrace a nut or a square on a coupling.

Form. 1. (*Printing.*) *a.* A body of type, composed and made ready for printing.

b. A stereotype in the like condition of readiness.

The one containing the first page is the *outer form*. The *form* for the opposite side of the sheet is the *inner form*.

2. A shape or mold for metal, glass, or jelly.

Form'er. A shape around which an article is molded, woven, wrapped, pasted, or otherwise constructed.

A templet, pattern, or gage by which an article is shaped, as pottery, or an object in the lathe.

A cutter by which patterns, blanks, wads, or pieces are cut from sheets for various purposes.

Form'ing. (*Shipbuilding.*) Shaping exactly the converted (partially shaped) timbers, so as to give them the required figure. This consists in: —

Siding; giving them the correct breadth.

Molding; giving the correct outline and depth.

Beveling; giving the faying surface the proper shape to meet the planking or iron skin.

Form'ing-cyl'in-der. (*Paper.*) That cylinder in a paper-making machine on which the film of pulp is gathered, and which delivers it as a soft and weak web to the hardening and drying devices.

For'ril. Lambskin parchment. Vellum.

Fort. A small fortification.

The *orthography* of a fort is its profile.

The *ichnography* is its ground plan. See FORTIFICATION.

Fort'al-ice. An outwork of a fortification.

For'ties. (*Printing.*) A sheet of paper having forty printed pages on each side. 40's.

For'ti-fi-ca'tion. Fortifications are known as, —

Natural, when cliffs, swamps, rivers, etc., conduce to give the advantage to the defending force.

Artificial, when labor and skill create advantages or add to the natural ones.

Defensive, when opposed to an attacking force.

Offensive, in investing a place.

Permanent, of a lasting character.

Field, for emergency or temporary uses.

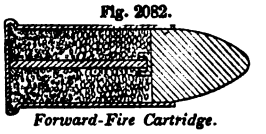
For'tress. A large permanent fortification, such as, on our continent, Fortress Monroe, Quebec, St. Juan de Ulloa, Moro Castle. They are too numerous in Europe to be thus summarily cited.

For'ty-eightmo. (*Printing.*) A book made up of sheets printed 48 pages on a side. 48mo.

For'ward-fire Car'tridge. One in which the fulminate is at or in the base of the ball, forward of the powder. It is exploded by a stem *d*, as in the figure, or else by a needle which penetrates the whole extent of the powder, and strikes the fulminate in the base of the bullet. See NEEDLE-GUN.

Fig. 2082.



Forward-Fire Cartridge.

For'ward-ing. (*Bookbinding.*) That department which concerns the operation of plain covering a sewed book, ready for the finisher.

Fosse. (*Fortification.*) A moat or ditch around a fortification.

An *advance fosse* is a ditch encircling the glacis or esplanade of a fortification.

Foth'er-ing. (*Nautical.*) A mode of stopping a leak at sea by thrumming a sail with oakum and yarn and drawing it under the bottom so as to clog the aperture.

Fou'cault's Pen'du-lum. A pendulum for rendering visible the diurnal motion of the earth.

It consists of a *bob* suspended from a considerable hight, say the apex of the dome of the Pantheon or Capitol, and set to vibrating above a circular table marked with degrees. Owing to certain independence of motion which the *bob* possesses, vibrating in space, as it were, the earth in its diurnal motion turns round beneath it, as is evidenced by the *apparent* change of direction of the *bob* relatively to the graduated table. See PENDULUM.

Fou-gasse'. (*Fortification.*) A small mine, consisting of a hole charged with combustibles and projectiles hidden by earth, and placed in a position liable to fall into the hands of the enemy.

Fou-lard'. (*Fabric.*) A thin silk or silk-and-cotton dress-stuff.

Found. 1. A three square, *single-cut* file or *float*, with one very acute angle, used by comb-makers. See COMB.

2. To cast; as metal.

Foun-da'tion. 1. The bed or basis of a structure.

2. (*Hat-making.*) The body of a hat, of wool or inferior fur, upon which the napping of superior fur is laid and united at the *battery*.

Foun-da'tion-bolt. One which keeps a bed-plate — of an engine, for instance — down to its substructure.

Foun-da'tion-muslin. (*Fabric.*) An open-worked, gummed fabric, used for stiffening dresses and bonnets.

Foun-da'tion-pile. (*Hydraulic Engineering.*) One driven into soft or treacherous ground to form — with others — an unyielding basis for a structure.

Foun-da'tion-plate. 1. (*Bookbinding.*) The base plate on which ornaments are arranged in the stamping or embossing press.

2. (*Steam Engineering.*) The bed-plate of a steam-engine.

Found'er's Cleans'ing-mill. A *tumbling-box* in which small castings are cleansed from adhering

Digitized by Google

sand. In a similar box articles may be polished or rounded by mutual attrition, assisted, if need be, by an abradant, such as sand or emery.

Found'er's-lathe. A lathe used in preparing the cores for loam-molding, such as those for iron pipes. A central spindle, being prepared, is placed on centers or on V's, and the clay loam covering is plastered on and regulated by a templet or pattern.

Found'ing. The art of casting metals. See under the following heads : —

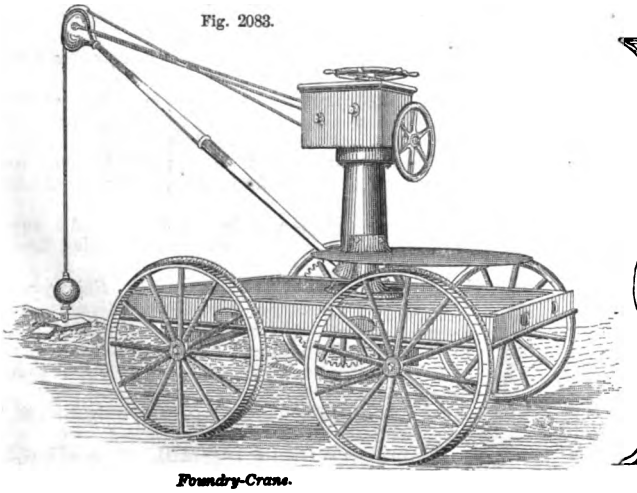
Foun'dry-crane. One used to lift and transport molds, flasks, castings, etc., in a foundry. Also known as a molding-crane, from its being used for lifting into and out of position the drags of molds, cores, and what not, in heavy casting, loam-work, and pit-casting. See CRANE.

Fig. 2083.



Foundry-Crane.

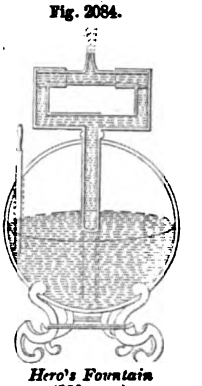
Fount. An assortment of printer's type. See FONT.

Foun'tain. 1. An upward jet of water, natural or artificial. With the latter we have alone to do.

Many ingenious pneumatic and hydraulic devices are shown in "Spiritalia Heronis," 150 B. C. Some were toys merely, and some, probably, were a part of the illusive machinery of the temples.

In the fountain of Hero, the motion of a column of water is transmitted to another by the intervention of a body of air between the two. The pressure of the elevated body of water compresses the air in a lower chamber; the pressure is transmitted to the air in a chamber above, the water of which is ejected in a jet.

Fig. 2084.



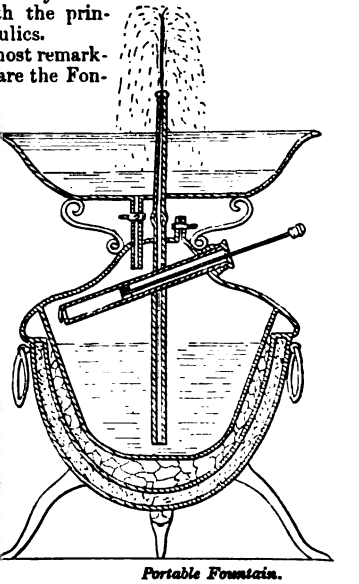
Hero's Fountain (150 B. C.).

The principle has been made use of in emptying the water from the mines of Schemnitz, Hungary. (See Fig. 58.)

Hero has anticipated by 2,000 years some of the modern parlor fountains, in which a body of compressed air above the water in the reservoir below is made the means of driving a jet of water into the air. An adjustment in two planes is given to the nozzle, so as to direct the stream in the required direction.

This contrivance, which appears simple enough when exhibited in section, was one of the hydraulic marvels of the pagan priests. Fig. 2085 is a late form, which has an ice-chamber and non-conducting casing. The gardens of Montezuma were adorned and nourished by streams and fountains. For the former they were indebted to extensive aqueducts. The possession of the latter shows that they were acquainted with the principles of hydraulics.

Fig 2085.



Portable Fountain.

Among the most remarkable fountains are the Fon-

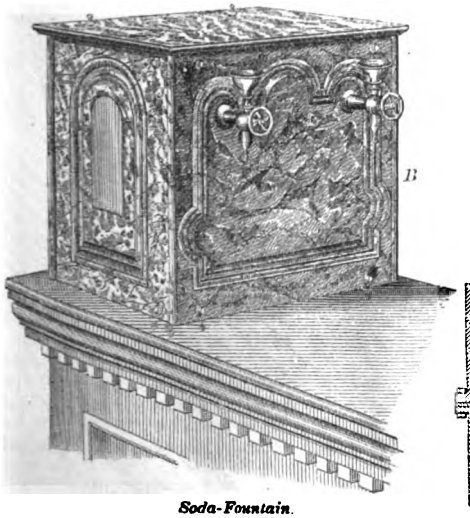
Digitized by Google

tana di Trevi at Rome, constructed for Pope Clement XII. in 1735; the Fontana Paolina, erected for Pope Paul V. in 1612; the Fontana dell' Acqua Felice, or Fountain of Moses. The fountains of Versailles, made for Louis XIV., and the Jet d'Eau of St. Cloud, are much admired. The fountains of Chatsworth, in Derbyshire, England, the residence of the Duke of Devonshire, are particularly grand; as are also those of the Crystal Palace at Sydenham, near London. Cincinnati is also proud of a fountain made in Germany, and of a very Teutonic aspect.

2. The "beer fountain," as it is called, used for drawing liquors in a tavern bar from barrels in the cellar, by means of a force-pump, is the invention of Bramah, and was patented by him.

3. A copper vessel *A* (Fig. 2086) containing aërated water for a beverage. It is used in connection with

Fig. 2086.



Soda-Fountain.

an ornate counter arrangement through which the liquid is drawn into tumblers. They are lined with block-tin to prevent corrosion of copper.

4. A box *B* containing ice and a coil through which aërated water, known as "soda-water," is conducted to the nozzle, when it is drawn into glasses.

The sirup fountain is for the supply of the sirup which flavors the "soda," so called.

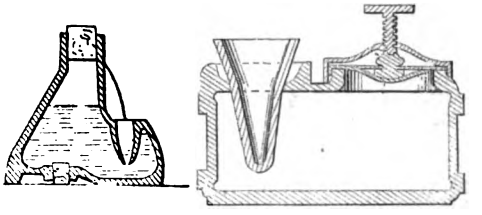
5. An upper reservoir chamber to contain a liquid and supply a wick, a dip-hole, a trough, etc. As in the oil-chamber of an Argand lamp, the reservoir of an inkstand, a drinking-glass in a bird-cage, etc.

6. The ink-reservoir in a printing-press.

7. The supply-chamber in a reservoir pen.

Foun'tain Ink'stand. One which has a continual supply of ink from an elevated fountain (see Fig. 2087), or which has an elastic diaphragm by which the dip-cup may be supplied or emptied, as in Fig. 2088.

Fig. 2087. Fig. 2088.



Fountain-Inkstands.

Foun'tain-lamp. One with an elevated reservoir for supply, as in most forms of the Argand, — the student's lamp, for instance.

Gerard used an air-pump to force oil from a low chamber to the burner of an Argand lamp, so as to avoid throwing a shadow upon surrounding objects.

Foun'tain-pen. One which has an ink reservoir for the supply of the pen.

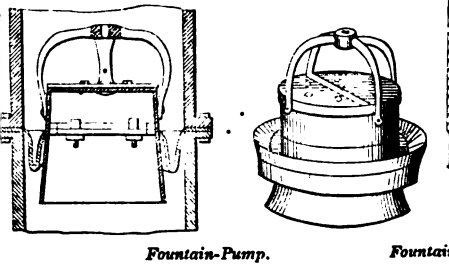
Scheffer's fountain-pen, introduced in England about 1835, had a reservoir of ink in the holder, and the ink is admitted to the pen by the pressure of the thumb on a projecting stud.

Fig. 2089.

Parker's hydraulic pen, invented about the same time, had a piston in the holder, operated by a screw stem and a nut on the end of the holder. The lower end of the reservoir being dipped in ink, the piston was drawn up by rotating the nut, filling the reservoir. The ink was ejected as required by the contrary motion of the thumb-nut.

Foun'tain-pump. 1. One in which a stream with a natural head is led through a

Fig 2090.



Fountain-Pump. *Fountain-Pen.*

stock and nozzle, and thus bears the appearance of a pump, though perennial.

2. One in which a packed piston is replaced by a plunger with a leathern annular disk or diaphragm.

Four-cant. (*Nautical.*) A rope of four strands.

Four-chette'. 1. (*Surgical.*) An instrument

Digitized by Google

for holding up the tongue while the frenum is being cut.

2. (*Glove-making.*) The forked piece between two adjacent fingers of a glove, uniting the portions of the back and inside of the finger. *Fougette.*

Four'dri-nier'-ma-chine'. A paper-making machine, the first to make a continuous web. It was invented by Louis Robert, of Essonne, and patented by him in France. He experienced some pecuniary difficulties, and sold the right to M. Leger-Didot. The latter came to England and made arrangements for working it. A Mr. Gamble and the brothers Fourdrinier improved it, and made a valuable machine which was pirated, and bankrupted the gentlemen whose name is imperishably associated with it. The enterprise is the glory of the mechanical genius, and the disgrace of the law lords and law courts of the "tight little island."

The machine was perfected by Bryan Donkin, John Wilks, and others not known to fame.

The essential features of the machine are: —

1. A stream of paper pulp flowing on to the surface of an endless, horizontal, wire web.

2. A tremulous motion to the web to shake out the water, which falls in a rain beneath, and to felt the fiber.

3. A traveling deckle which keeps up with the motion of the web, and forms the lateral margin of the paper.

4. A porous *dandy* which presses the pulp and absorbs some of the water.

5. A couching roller to take up the web.

6. A pressure roller to abstract moisture.

7. Drying, sizing, finishing, measuring, cutting devices, *ad. lib.* See PAPER-MACHINE.

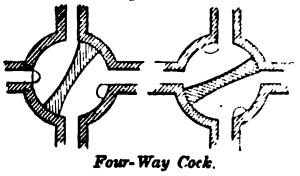
Four'gon. 1. A tumbrel or ammunition-wagon.

2. A French baggage-vehicle.

Fourth-rate. Formerly a 50 to 70 gun vessel, now a gunboat carrying from 1 to 4 guns.

Four-way Cock. A cock having two separate passages in the plug, and communicating with four pipes. The invention of James Watt.

Fig. 2091.



Four-Way Cock.

Fowl'ing-piece. A fire-arm adapted for ordinary sporting. See FIRE-ARM.

Fox. (*Nautical.*) A small strand of rope made by twisting several rope-yarns together. Used for *seizings, mats, sennits, gaskets.*

Fox-bolt. A description of bolt which is made tight by a *fox* or wedge driven into a split in the end. See BOLT.

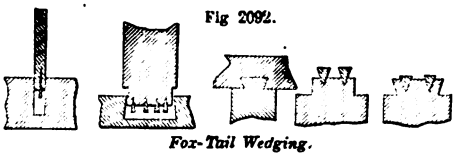
Fox'ing. (*Shoemaking.*) 1. An outer covering or upper leather over the usual *upper.* One mode of repairing a worn upper by clothing it.

2. Ornamental strips of a different material on the uppers of shoes.

Fox-key. (*Machinery.*) A split-cotter with a thin wedge of steel driven into the end to prevent its working back.

Fox-tail Saw. A dovetail saw.

Fig 2092.



Fox-Tail Wedging.

Fox-tail Wedg'ing. A mode of spreading the end of a tenon in the mortise, so as to give it a dovetail character to resist withdrawal. The same is applied to wooden pins which occupy holes not bored through. In the point of the pin is inserted a thin wedge of hard wood. When this reaches the bottom of the hole, it sinks into and spreads the end of the pin so as to bind it very firmly in the hole.

With a tenon, it is usual to insert a number of small wedges, so that it may not be split much at any one point.

Fox-type. (*Photography.*) A printing process in which a transparent positive is used, and the action of the light is the reverse of the usual process.

Foy'er. The crucible or basin in a furnace, to receive the molten metal.

Frache. A shallow iron pan to hold glass-ware while being annealed in a *leer.*

Frag'ments. (*Printing.*) A few pages at the end of a book. The title, preface, contents, etc., imposed so as to print off economically. *Oddments.*

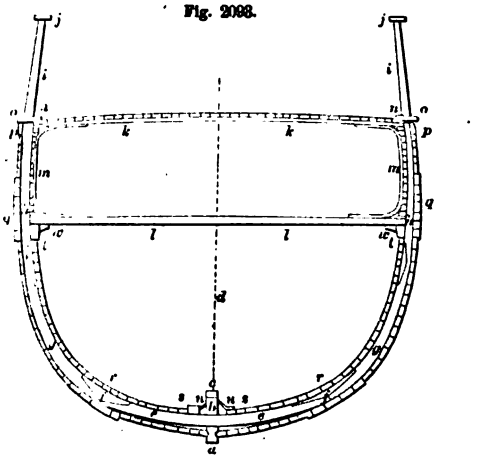
Fraise. 1. (*Fortification.*) Palisading placed horizontal at the crest of the scarp and projecting over the ditch.

2. A tool used by marble-workers to enlarge a hole made by a drill. It is grooved, and slightly conical.

Frame. The skeleton of a structure.

1. (*Shipbuilding.*) The parts of a ship's frame are shown in Fig. 2093, which represents a midship section.

Fig. 2093.



Ship's Frame.

a, keel.
b, keelson.
c, keelson-rider.
d, middle line or center line.
e, floor-timber, ground-futtock, or navel-futtock.
f, chock for filling to the timbers.
g, second futtocks.
h, top timbers.
i, rough-tree timber or stanchion.
j, rough-tree rail, or rail.
k, upper-deck beam.
l, hold-beam.
m, standard knees.
n, water-ways.
o, plank-shears.
p, sheer-strakes.
q, wales.
r, bilge-planks, inside and out.
s, futtock-planks.
t, clamps or sea-crafts.
u, limber-boards.
w, shelf-pieces or stringers.

2. The strong work which supports the engine and boilers of a locomotive upon the wheels, and known as *inside* frame or *outside* frame, according to the position of the wheels relatively to the frame.

3. The head of the batten in a loom.

Digitized by Google

4. The ribs and stretchers of an umbrella, or other structure with a fabric covering.

5. (*Carpentry.*) *a.* The skeleton structure of a wooden building, consisting of sills, posts, beams, sleepers, joists, and rafters, with the studding that is to form partitions.

b. The outward work enclosing a door or window.

c. The part of a door or window enclosing panels.

d. A border or inclosure for a picture, or panes of glass.

6. (*Horology.*) That which contains the mechanism of a watch or clock. It consists of two *plates* and a sufficiency of *pillars*; usually four.

7. (*Printing.*) A desk containing two pairs of cases, containing roman and italic letters for the use of a compositor (see CASE), or the stand supporting them.

8. A structure of four bars arranged in a square and adjustable in size, on which cloth or other fabric is stretched for quilting, embroidery, etc.

9. A term applied, especially in England, to machines built upon or within a framework of timbers — e. g. the *stocking-frame, lace-frame, water-frame, silk-frame*, etc. It is one degree more complex than the *quilting-frame, tambour-frame, embroidery-frame, glass* or *picture frame*; or a *window* or *door frame.*

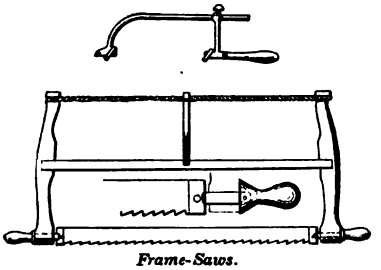
10. (*Soap-making.*) A box whose sides are removable when required, and locked together when the soap is to be poured in. As soon as the soap has acquired sufficient solidity, the sides are unlocked and taken down, exposing the block of soap, which is then cut up by wires which are passed through it to divide it into parallelopipeds.

Frame-lev'el. A mason's level.

Frame-saw. A thin saw stretched in a frame which gives it sufficient rigidity in its work.

The *buhl-saw*, for enlarging, is of this character. It is common to make the handle-attachment at each

Fig. 2094.



Frame-Saws.

end rotatable, so as to present the saw-edge in any direction.

A frame-saw is shown in a painting at Herculaneum. The sawyers are at each end, one standing and the other sitting. The bench to which the timber is secured by cramps is supported by four-legged stools. The saw-frame is square and the saw-blade is strained in the middle; the teeth stand perpendicularly to the plane of the frame.

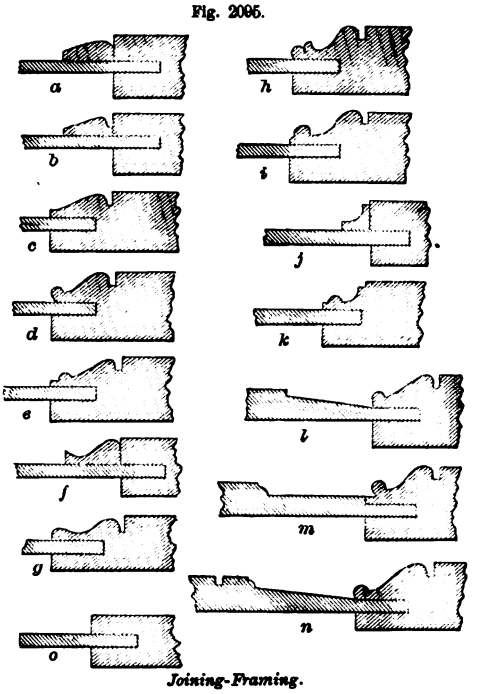
Frame-saws were common in Egypt many centuries previous to this time.

Fram'ing. 1. A mode of putting parts of a structure together

Joinery framing is of various descriptions, as square, bead, bead and fillet, ogee, etc., etc. See the following examples, which all have *flat panels and square backs*: —

a, ovolo and square.
b, quirk-ovolo.
c, quirk-ovolo fillet.
d, quirk-ovolo bead.
e, quirk-ovolo cock-bead or bead and fillet.
f, ogee and square.
h, quirk-ogee and quirk-bead.
g, quirk-ogee.
i, quirk-ogee, bead, and fillet.
j, cavetto.
k, cavetto, bead, and fillet.

Fig. 2095.



Joining-Framing.

The following vary in the *panels*: —

l, quirk-ovolo and bead, raised panel and square back.

m, quirk-ovolo and bead, raised panel with ovolo on the rising, and square back.

n, quirk-ovolo and bead, raised panel, with ovolo on the rising groove round the face, and square back. The list might be much extended.

o is square-framing, the simplest description of framing, having no molding on either side.

2. (*Mining.*) An operation upon pounded or stamped ores by which they are sorted into grades of comparative weight and consequent richness.

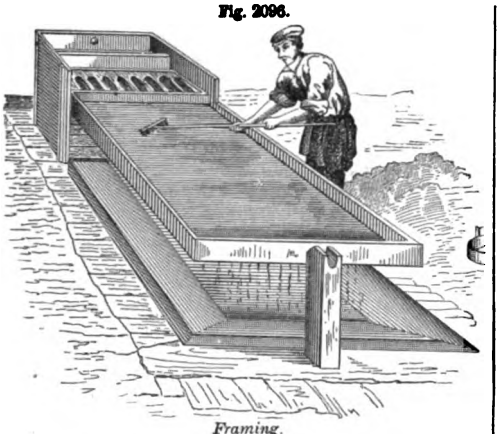
The *framing-table* is eight feet long, four feet wide, and has a ledge around it. It is suspended in an inclined position, on pivots, so that it may be tipped into a vertical position when full, discharging its contents into separate cisterns beneath; the reason for the separation of the receptacles will be apparent presently.

At the upper end of the frame is the jagging-board, over which the sluices are so distributed that a small stream of water shall carry them gradually down on to the frame. The richer portions of the ore rest upon the upper part of the frame, and the poorer, lighter portions are carried farther down; light impurities escape with the water at the lower part of the frame. The ore on the frame is occasionally stirred with a rake, that every portion may be subjected to the action of the water.

When the *frame* is sufficiently full, the latch which held it horizontal is lifted, and the frame tipped up into a vertical position, so as to tip out its contents, which fall into the vats beneath. These

Digitized by Google

Fig. 2096.



Framing.

vats are arranged in a row, so that they may respectively receive the *slimes* which have accumulated nearer to or farther from the head of the frame, the richness being determined by the proximity to the head or upper portion. The frame is then readjusted, a quantity of slimes spread on the *jagging-board*, and the operation recommences.

The contents of the cisterns are treated by subsequent processes of a nature adapted to their respective qualities. Analogous processes are described under BUDDLE; TRUNK; KEEVE; JIGGER; TYE, etc. (which see).

Fram'ing-chis'el. (*Carpentry.*) A heavy chisel for making mortises. It has a socket-shank which receives the wooden handle on which the blows of the mallet are delivered.

Frank'ing. (*Joinery.*) The notching out a portion of a sash-bar for the passage of the transverse bar, to make a miter-joint.

Frap'ping. 1. (*Nautical.*) *a.* The binding together of the several ropes of a tackle at a point between the blocks, so as to increase still farther the tension.

b. Securing a ship in emergency by wrapping ropes around it, to prevent starting of the planks.

"They used helps, undergirding the ship."—*Luke's account of Paul's voyage.*

2. Bracing the cords of a drum by pulling them together.

Free'board. (*Shipwrighting.*) So much of the vessel's side as is included between the *plank-sheer* and the water-line.

Free-reed. (*Music.*) An elastic tongue, usually of brass, and playing in a long rectangular opening in a plate to which one end of it is riveted. The name *free-reed* is given to distinguish it from the reed which batters against the seat, as in the clarinet, some organ-pipes, the bassoon, and oboe. These *battering*-reeds are usually of wood. The *free-reed* is used in the accordeon, melodeon, concertina, harmoneon, parlor-organ, and in most of the reed-pipes of organs.

Fig. 2097.

Free-Reed.

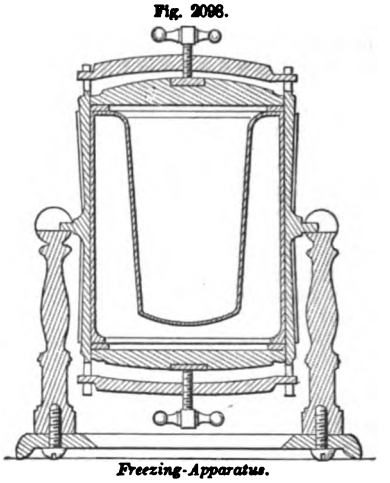
The opening in the plate is slightly larger than the margin of the tongue, so that the portion of the latter concerned in the vibration does not batter against or touch the plate. At one end is a stud by which the plate is drawn in or out from the seat of the reed over the aperture whence it derives the air-blast producing the vibration and the consequent musical tone. At some point on the plate is denoted the note to which the tongue is tuned.

Free'stone. An oölitic stone, so called from the facility with which it is rived in any direction.

Free-stuff. (*Carpentry.*) Timber free from knots. *Clear-stuff.*

Freez'er. An apparatus in which cream or other food is placed to be frozen. In the example, the liquid to be congealed or cooled is contained in a metallic cylinder inclosed by another cylinder and surrounded by the chemical refrigerating substances, the apparatus being rotated or oscillated to thoroughly agitate the liquids, and bring new particles to the cold surface.

Fig. 2098.



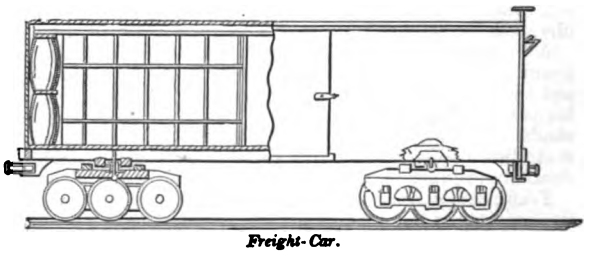
Freezing-Apparatus.

Master's machine for icing drinks consists of a central cylinder for the confectionery, a surrounding cylinder for the freezing mixture, and one outside of this again, for containing water. The inner cylinder is rapidly revolved, its contents become frozen, and the water in the outer vessel becomes a hollow cylinder of ice, in which a decanter may be set to ice its contents.

Freez'ing-mix'ture. A mixture of salt and pounded ice; or a combination of chemicals with or without ice. See ICE-MAKING.

Freight-car. One constructed for the carriage of merchandise.

Fig. 2099.



Freight-Car.

Freight-en'gine. (*Steam Engineering.*) A locomotive adapted for drawing heavy trains at moderate speed. The drivers are coupled together so as to increase adhesion, and are of smaller diameter than usual with passenger engines adapted for more rapid transit.

Digitized by Google

French-bit. (*Carpentry.*) A boring tool adapted to use on a lathe-head or by a bow. It is intended for boring hard wood, and approaches the characteristics of a *drill*. See BIT.

French-fly'ers. (*Carpentry.*) Stairs that fly forwards until they reach within a length of a stair from the wall, where a quarter space occurs; the steps next ascend at a right angle, when another quarter space occurs; they then ascend in an opposite flight, parallel to the first direction.

French-horn. A wind-instrument formed of metal, having a circular shape and a gradual taper from the mouth-piece to the flaring pavilion. See HORN.

French-pol'ish. A solution of resin or gum resin in alcohol or wood naphtha. A good recipe is, shellac, 1½ pounds; spirits of wine, 1 gallon. Or, shellac, 2½ lbs.; gum mastic and sandarac, each 3 ounces; alcohol, 1 gallon; copal varnish, 1 pint. Or for a dark color, shellac, 1 pound; benzoni, ½ pound; alcohol, 1 gallon. Or, shellac, 1½ pound; guaiacum, ¼ pound; alcohol, 1 gallon.

It is laid on with a sponge, a brush of wadding enveloped in a rag, or a rubber made of a roll of list. These are saturated with the varnish which they gradually yield by pressure to the surface of the wood, over which they are kept in constant motion in uniform circular strokes. The surface of the rubber is covered with an oiled cloth, which is renewed as it becomes clogged.

French-roof. A roof having portions of two different pitches. A *curb* roof. A *Mansard* roof.

French-win'dow. A large casement window, moving on hinges instead of sliding vertically in grooves. A *casement*.

Fres'co. A mode of painting in which the colors are mixed with and laid on in the manner of plaster.

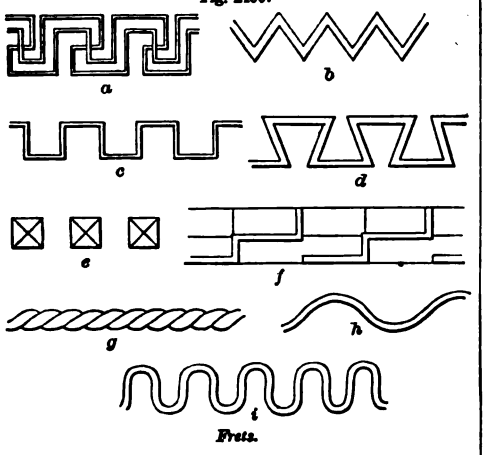
The picture is prepared as a cartoon, and is pricked through on to the soft surface of plaster upon which the fresco is to be placed.

The surface is rough, and is damped to receive the colors, which are mixed and ground up with lime.

A solution of silex instead of lime was used by Oberrath von Fuchs, being laid on a chemically prepared ground. It becomes exceedingly hard.

Fret. 1. An ornament of zigzag, interlacing, or variously contorted fillets, used as an architectural

Fig. 2100.



Frets.

decoration. Some frets are included in the following: —

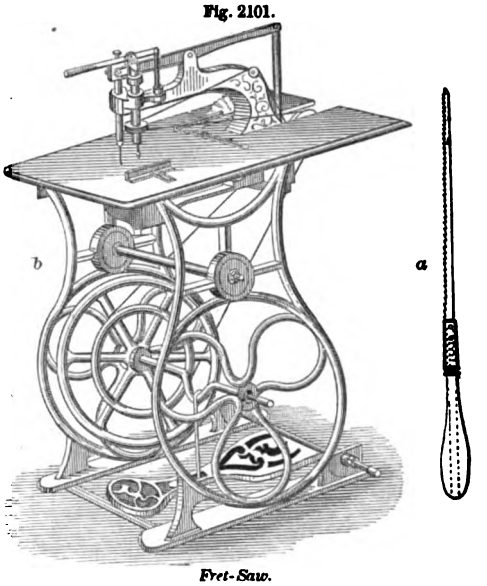
a, intersecting fret.
b, zigzag or chevron molding.
c, embattled fret.
d, triangular fret.
e, nail-head fret.
f, billet-fret.
g, cable-molding.
h, wavy molding.
i, nebular molding.

2. (*Music.*) One of the bars of wire on the finger-board of a guitar and some other instruments, to indicate where the fingers are to be placed for playing certain notes.

Fret-saw. 1. A saw (*a*) with a relatively long, narrow blade, used in cutting the frets, scrolls, etc., on verge boards, ornamented screens, etc. A *key-hole saw*; a *compass-saw*.

2. A machine (*b*) mounted on a stand with a treadle to give the reciprocating motion to the gig-saw. The

Fig. 2101.



Fret-Saw.

machine shown is specially intended for fret-work on a small scale, ornamental inlaying, buhl and reisner work (which see).

Fret-work. 1. (*Glazing.*) A mode of glazing in which a number of separate pieces of stained glass are fitted together in leaden *cames* so as to form patterns. The *cames* are fastened by leaden bands to *saddle-bars* of iron, which cross the window-frame.

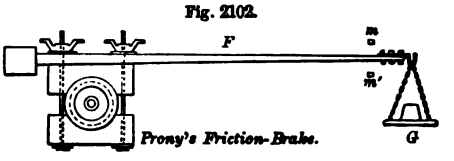
2. (*Wood.*) Carved or open wood-work in ornamental patterns and devices.

Fri'ar. (*Printing.*) A pale patch in a printed sheet.

Fric'tion-balls. Balls placed beneath a traversing object to relieve friction. Some forms of swing-bridges are thus supported. Properly, *anti*-friction balls.

Fric'tion-brake. A form of dynamometer in-

Fig. 2102.



Prony's Friction-Brake.

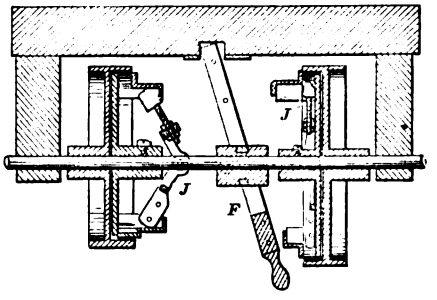
vented by Prony, in which a pair of friction-blocks are screwed to a journal rotating at a given speed,

Digitized by Google

and tightened to such an extent that the unweighted lever will remain horizontal between the studs m m'.

The shaft is now set in motion by the prime mover, the screws are then gradually tightened to such a degree that the shaft moves exactly with the velocity at which its useful effect has to be determined. Were it not for the stud m, the lever, with the whole brake apparatus, would move round in a circle with the shaft, so that this stud has to withstand a certain force from the lever pressing against

Fig. 2103.



Brown's Friction-Clutch.

it. Now place gradually upon G such a weight as will counteract the pressure of the lever against m, and bring it back to its horizontal position. It is evident that this weight, in combination with the lever F, expresses the amount of friction between the blocks and the drum.

Fric'tion-clutch. A device for connecting two shafts by bringing a piece on one shaft in contact with a piece on another shaft, which revolves with such force that the former partakes of the motion of the latter.

In Fig. 2103, the shipper-handle F carries the shaft, and with it the toggles J J, expanding the segments against the rim of the pulley. See also CLUTCH.

Fric'tion-cones. A form of friction-coupling in which the connecting portions have respectively a conical disk and a hollow cone, which become frictionally adherent by contact.

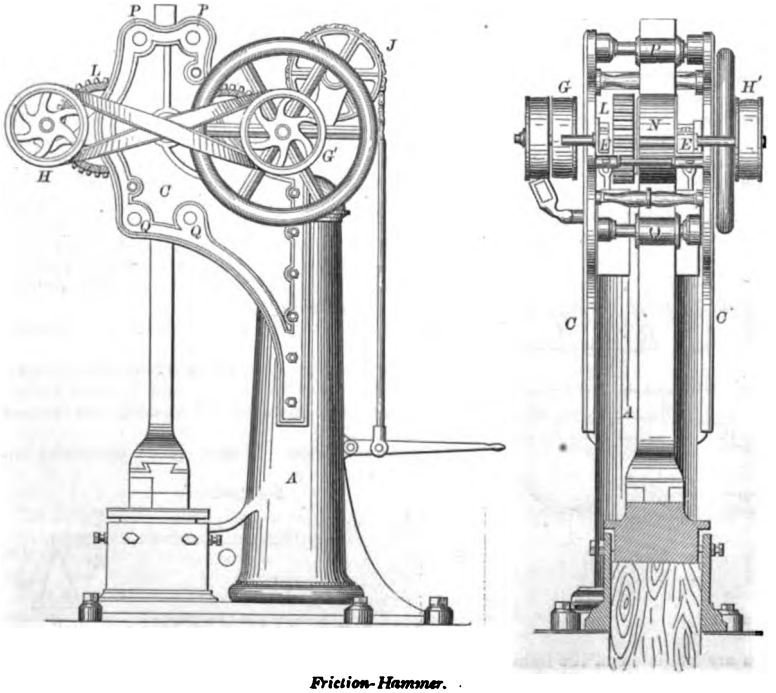
Fric'tion-coup'ling. See FRICTION-CLUTCH.

Fric'tion-gear. Wheels which act upon each other by the adhesion of their contacting surfaces, instead of by cogs, bands, or chains.

Fric'tion-ham'mer. One deriving its name from the hammer being lifted by means of the friction of revolving rollers, which nip the hammer-rod. The framework consists of a pillar A, to which are bolted the two cheeks C C carrying the working apparatus. On the oscillating frame E E are the plummer-blocks for the spindles, carrying the driving gear and friction-rollers. The motion is, in the first instance, communicated to the drum G, and consequently to G', fixed upon the same shaft; this communicates the motion by means of a crossed strap to the drum H, and hence also to a pinion which works into the spur-wheel L fixed upon the same shaft with the friction-roller N. In a similar manner, a friction-roller on the other side of the hammer-rod is set in motion by means of a spur-wheel and pinion deriving motion from the drum G'.

The friction-rollers have wooden rims. The oscillating frame E, when tilted upon its axis, causes the friction-rollers to nip the hammer-rod, the one a little above, the other a little below, the axis. When the frame E resumes its horizontal position, the hammer is allowed to fall, being guided by the rollers P P and Q Q. The tilting of the frame is done by means of the lever, connected with the same by means of the rod and chain passing over the fixed pulley J.

Fig. 2104.



Friction-Hammer.

Fric'tion-pri'mer. A small brass tube filled with gunpowder, and having a smaller tube containing friction composition inserted at right angles near the top. The composition is ignited by means of a roughed wire inserted in the smaller tube, which is rapidly drawn out by a lanyard having a hook at the end.

The composition consists of 2 parts sulphuret of antimony and 1 part chlorate of potassa, moistened with gum water and dried.

Fric'tion-pul'ley. See FRICTION-CLUTCH; CLUTCH.

Fric'tion-tube. (*Ordnance.*) A tube containing a composition which is inflamed by friction, and which is placed in the vent of a gun to ignite the charge

Digitized by Google

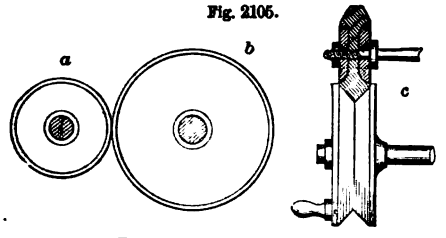
when the lanyard is pulled. See FRICTION-PRIMER.

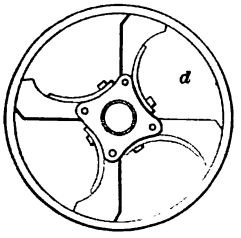
Fric'tion-wheel. A wheel the motion of which is caused by the friction of a moving body, or, conversely, which communicates motion to a body by frictional contact. In the annexed illustration *a b*, one wheel being driven becomes a motor to the other, their perimeters being in contact. The surface is usually clothed with leather, rubber, or some sufficiently elastic material which does not polish too readily, and thus induce slipping.

By grooving the perimeters of the wheels, the contact may be made more intimate, as the surface engaged is increased, and the elastic material of the respective faces caused to bind.

The term *friction-wheel* is often, but erroneously, applied to wheels which diminish friction; these are properly called ANTI-FRICTION WHEELS (which see.)

Fig. 2105.





Friction-Gearing.

Howlett's friction gearing *c* has an upper india-rubber wheel with a V-edge, clamped between two metallic plates. By screwing up the nut which holds the parts together, the disk is made to expand radially, and thus increase the tractive power on the lower driving-wheel.

d shows another form. A collar fastened to the central shaft has four pivoted arms. When the rim turns in one direction, the arms turn on their pivots, leaving the rim and failing to transfer the motion to the shaft.

When the rim turns in the contrary direction, the arms catch against it and are rotated by the contact, turning the shaft also.

The friction-wheel feed, by which logs are fed to the gang-saws in the large lumber-mills of Ottawa, Canada, consists of a horizontal wheel 40 inches in diameter, and an upright one driven by band from the engine-shaft, and 24 inches diameter. (See Fig. 1601.)

The horizontal wheel is vertically adjustable by a hand-wheel and shaft on the working floor of the mill, the friction-wheel slipping on a spline. As the said wheel approaches towards the center of the driving-wheel, the speed of the feed is lessened, and conversely; if it cross the center, the motion is in the other direction, and the feed is reversed.

Frieze. 1. (*Architecture.*) A flat member of an entablature between the architrave and cornice.

Frieze-panel; one of the upper panels of a six-panel door.

Frieze-rail; the one next to the top rail.

2. (*Fabric.*) A coarse woolen cloth.

Frig'ate. (*Vessel.*) The original frigate was a Mediterranean vessel propelled by sails and oars.

It is now a vessel of war, having an upper flush deck (spar-deck) and one covered gun-deck (main-deck). The armament is from 28 to 44 guns.

The grade is below a man-of-war and above a *corvette.* The rating of iron-clads is different; the guns being larger and fewer in number.

Frig'a-toon. A Venetian vessel with a square stern, main-mast, jigger-mizzen, and bowsprit.

Frig'er-a-to-ry. A cooling-chamber.

A chamber maintained at a low temperature for the preservation of meat or vegetables.

Frill'ing. A species of plaited or fluted edging or trimming of fine linen. The gathered or plaited edge is sewn to a band, and the crimped or ruffled edge forms a collar, a cuff, or an ornament to a shirt-front.

Fringe-loom. One in which the weft-thread is carried and detained beyond the limit of the warp, which has thus a series of loops beyond the selvage.

Frisk'et. (*Printing.*) A rectangular frame having tapes, cords, or paper stretched across it for holding the sheet to the *tympan.*

The frisket is a frame around the type-form, and keeps the margin of the paper clean.

Frit. (*Glass-making.*) A calcined mixture of sand and fluxes ready to be melted in a crucible to form glass.

The term is also applied to other vitreous combinations or compositions for use in manufacturing. It is not applied to manufactured articles, but to those in course of conversion, as the calcined kelp and lead, which are ingredients in the glaze of delft-ware.

A *frit-mixer* is a horizontal cylinder with oblique beaters, or a box with semi-cylindrical bottom and a rotating shaft with beaters or stirring arms.

Frit-brick. (*Glass-making.*) A lump of calcined glass materials, which have been united and brought to a pasty condition in a reverberatory furnace preliminary to the perfect vitrification in the melting-pot. See FRITTING-FURNACE.

Frith. (*Hydraulics.*) A fish-weir.

Frit'ting-fur'nace. (*Glass-making.*) A reverberatory furnace in which the materials for making glass are calcined (*fritted*) as a process preliminary to melting. The object is to effect a partial union of the silicic acid and alkali, to avoid volatilization of the latter in the subsequent vitrification.

The materials (sand, chalk, soda-ash, and cullet) being introduced into the furnace, the temperature is gradually raised for three hours. The pasty mixture is stirred, and the temperature increased to incipient fusion. The stuff is then raked out and transferred to the melting-pot, or is placed in cast-iron trays, cut into blocks by a spade, and stored away as *frit-bricks.*

Fri'zel. The movable plate of steel placed vertically above the pan of a gun-lock to receive the blow of the *snaphance.* The form of flint-lock which superseded the wheel-lock.

Friz'zing. 1. (*Leather-manufacture.*) A process to which *chamois* and *wash* leather are subjected after the skins are *unhaired, bated, scraped, fleshed,* and *raised.*

It consists in rubbing the skins with pumice-stone or a blunt knife till the *grain* appearance is entirely removed, the surface softened, and an even thickness obtained throughout.

2. (*Fabric.*) A peculiar finish given to certain kinds of cloth. See next article.

Friz'zing-ma-chine'. 1. (*Fabric.*) A machine on which the nap of woolen cloth is formed into a number of little prominences or tufts. Petersham cloth, so called, is thus formed.

The machine consists of three parts, — the *frizzer,* the *frizzing-table,* the *drawing-beam.* The cloth is drawn by the beam between the two former portions, which are respectively about ten feet long, fifteen

Digitized by Google

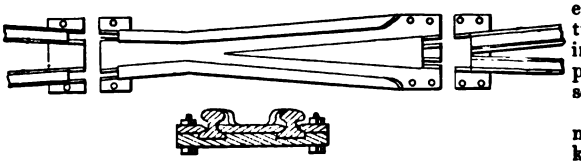
inches wide, and laid parallel, a short distance apart. The *table* is underneath, and its upper surface is covered with a coarse nappy cloth. The *frizzer* has a slow semicircular motion, and its surface is incrusted with a cement composed of glue, gum-arabic, and yellow sand.

The *drawing-beam* is covered with sharp points, and drags the cloth between the frizzer and the table, the latter preventing its being shifted about by the rotary reciprocation of the frizzer above, whose numerous protuberances catch the fibers of the cloth under treatment and roll them into little aggregated tufts or bunches, as the cloth is fed gradually through.

2. (*Wood-working.*) A bench with a circular cutter-head slightly protruding above the working surface, and adapted to dress boards which are passed over it.

Frog. 1. A section of rail at a point where rails diverge, or one track leads to two branches. In the illustration, a feature of connection is introduced,

Fig. 2106.



Railway-Frog.

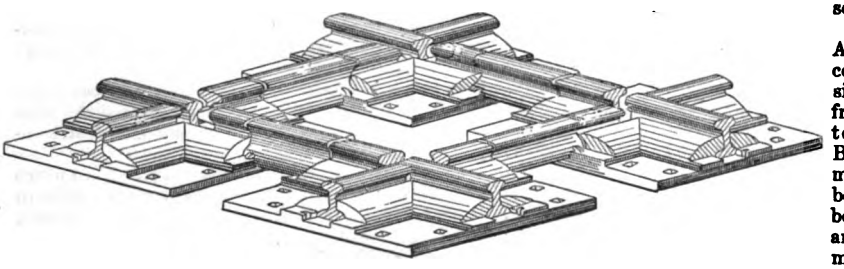
the end of the frog being dovetailed to receive the necks of the rails, and a chair placed under the dovetailed end. The chair has one or two recesses to support the rails, and suitable holes to receive the bolts.

A *cross-frog* is one placed at a rectangular intersection of railroad tracks.

2. A button or toggle of spindle shape and covered with silk or other material, which is passed through a loop on the opposite side of the breast of a military cloak or overcoat, serving to fasten the two breasts together.

3. The loop of a bayonet or sword scabbard.

Fig. 2107.



Cross-Frog.

Frog-plate. An accessory to the compound microscope in which the web of a frog's foot is exposed on the stage, to exemplify the circulation of the blood.

Front. (*Fortification.*) Two half-bastions and a curtain.

Fron'ton. (*Architecture.*) The decorated entrance to a building consisting of a cornice supported by consoles and surmounted by a pediment.

Frost'ed. The dead or lusterless appearance of gold, silver, or glass, when polishing the surface is omitted. It is supposed to resemble the *hoar-frost*, and hence the name.

Frosted work is introduced as a foil or contrast to *burnish* work, in which the metal receives the full luster by an agate or flint burnisher.

Electro-plated work is in the frosted condition as it comes from the bath, and may be burnished in whole or in part.

The frosted appearance on glass is given by grinding, making *ground glass*, which diffuses the rays, and does not transmit a direct ray or a clear image.

Frost'ed-glass. (*Glass-manufacture.*) A form of glass formerly made by the Venetians, and recently revived by Apsley Pellatt, who thus describes it: —

"Frosted glass has irregularly varied marble-like projecting dislocations in the intervening fissures. Suddenly plunging hot glass into cold water produces crystalline convex fractures, with a polished exterior, like Derbyshire spar; but the concave intervening figures are caused, first by chilling, and then reheating at the furnace, and simultaneously expanding the reheated ball of glass by blowing, thus separating the crystals from each other, and leaving open figures between, which is done preparatory to forming vases or ornaments. Although it appears covered with fractures, it is perfectly sonorous."

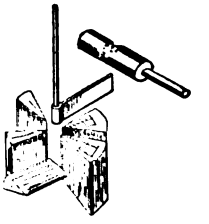
Frost-lamp. An oil-lamp placed beneath the oil-tube of an Argand lamp to keep the oil in a flowing condition on cold nights. Used especially in lighthouses.

Frost-nail. A roughing nail; driven into a horse's shoe in slippery weather.

Frow. (*Coopering.*) A cleaving tool for riving staves, shingles, or clapboards from the *balk* or *juggle*. *Frower*, *froe*.

It has a sharp edge, wedge-shaped blade, and a handle set in the plane of the blade, but at right angles to its length. It is driven by a mallet.

Fig. 2108.



Frow.

Frow'er. A FROW (which see).

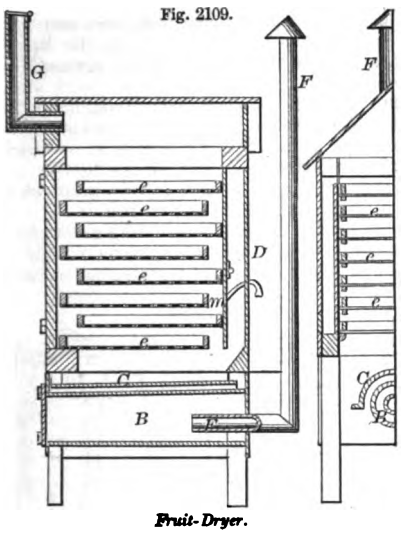
Fruit-box. A small box of certain dimensions in which fruit is shipped to market. Berry-boxes are made of strawboard, scaleboard, splints, and many other materials. Some of them are intended to be so cheap as to be sold with the fruit, others are frustums which pack in nests, others are collapsible for back shipment.

The larger fruits are carried in small crates, or open boxes made of slats.

Fruit-dry'er. A small house or kiln with furnace, shelves, and means for ventilation, used for drying fruits. There are many forms, which differ mainly in the arrangement of the parts named. In the example, the fire is made in furnace *B*, the heated surrounding air is deflected by plate *C*, passes in a

Digitized by Google

Fig. 2109.



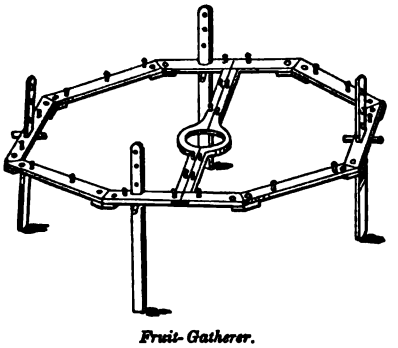
Fruit-Dryer.

sinuous course up among the shelves *e e*, and out at the duct *G*. The furnace *B* has its own flue *F*.

Fruit-frame. A trellis or espalier.

Fruit-gath'er-er. They are of two kinds. One in which a canvas is stretched beneath the tree to catch the fruit without bruising, as in Fig. 2110, which

Fig. 2110.

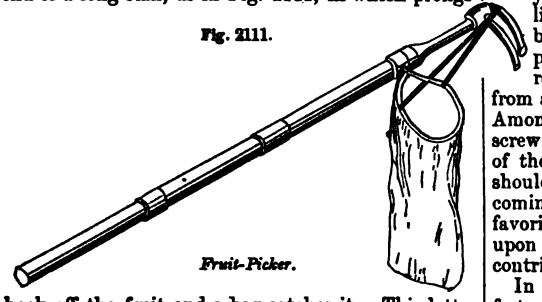


Fruit-Gatherer.

shows a jointed frame, over which a sheet is secured by the pins, the inner ring encircling the trunk.

Another form is really a fruit-picker, being on the end of a long staff, as in Fig. 2111, in which prongs

Fig. 2111.

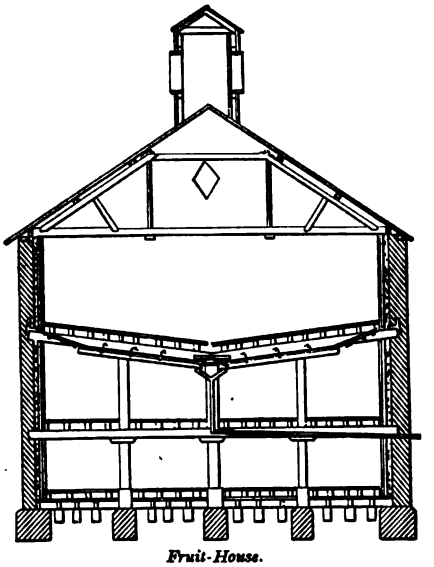


Fruit-Picker.

hook off the fruit and a bag catches it. This latter kind has many varieties, with different modes of grasping or cutting, catching, and leading down the fruit.

Fruit-house. A storage house for fruit. The walls hove double thickness, with intervening non-

Fig. 2112.



Fruit-House.

conducting material, and provision is made for effective ventilation.

The walls and floors have wooden surfaces with non-conducting linings or blank spaces between all inner surfaces and the outer walls or the earth. Ventilating entrances are at the level of the ice-floor, with hatches opening down to the storage rooms, and inclosed spaces to carry off bad air through the mass of ice upward when it is light air, and downward out at the bottom of the entrance-doors when it is carbonic-acid gas, the light air passing through the upper space above the ice, and thence out at the windows of the observatory.

Fruit-jar. Jars for preserving fruit are made of earthenware or glass, especially the latter. Some have been made of metal with porcelain (so called) lining, but these have met with little favor, as the acids of the fruits attack the lead of the enamel and destroy it, and themselves become unwholesome. The same remarks apply to the earthenware, whose glazing has generally salts of lead, and is therefore unfit for the purpose. Some kinds of glass even, where lead has been used as a flux, are not entirely beyond suspicion. Glass jars were formerly blown, like bottles, but are now usually pressed and blown in molds. The exercise of ingenuity has principally concerned the modes of closing, to render them air-tight, protecting the contents from access of oxygen and consequent fermentation. Among the devices for this purpose are lids which screw down on the threaded neck of the jar, the edge of the lid coming against a caoutchouc gasket on a shoulder of the jar, or a gasket on the lip of the jar coming against the inner surface of the lid. Another favorite form is a flat or flanged lid pressed down upon a gasket on the lip by some mechanical locking contrivance.

In the illustration are shown several forms of fastening the lid hermetically to the jar, after filling the latter and driving out a small remainder of air by the steam of the heated contents.

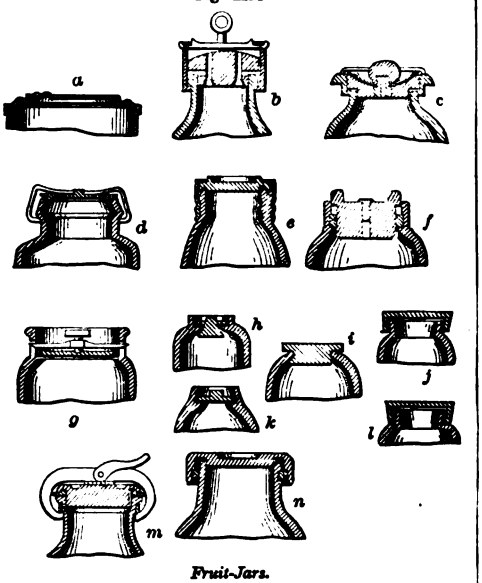
a is a tin can with a lid whose flange dips into a

Digitized by Google

trough on the can, which is closed by wax that is run into the trough.

b has a cover secured by hooks and a yoke, and pressed down upon a gasket on the lip. The holes in the lid are for the filling of any remaining space and the escape of the residual air. They are then both stopped.

Fig. 2113.



Fruit-Jars.

c has a cover secured by an elastic band which is held by lugs on the neck of the jar.

d has a cover secured by a yoke whose ends pass beneath inclined lugs on the neck so as to screw down the lid as the yoke is rotated.

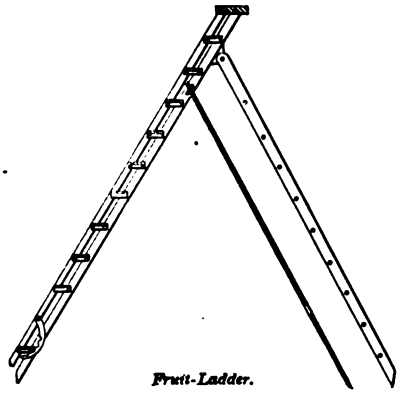
e has a glass lid, depressed by a sheet-metal screw collar, which engages the threaded neck of the jar.

f has a glass screw-stopper whose threads imbed themselves in the elastic gasket which is held in an interior groove of the neck.

g, a yoke fits in slots in the neck, and holds a center screw which presses the cover upon the gasket.

h i j k l are all forms in which an oval mouth admits the oval flange of the lid; the rotation of the latter brings the major diameter of the flange coincident with the minor axis of the opening, and locks the flange under the neck of the bottle.

Fig. 2114.



Fruit-Ladder.

m has a cover locked by a yoke and cam.

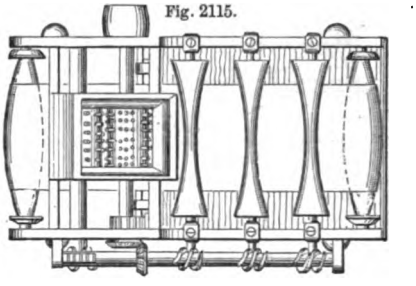
n has a grooved lid which holds the lip of the neck, and has a shoulder which fits against a gasket round the neck.

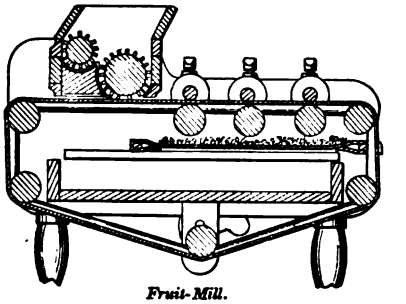
Fruit-knife. A knife for cutting fruit, having a blade which is not acted upon perceptibly by the acids of the fruit. Silver is the usual material.

Fruit-lad'der. A light ladder to rest against the limbs of the tree, or stand by itself while the picker stands upon it to gather fruit.

Fruit-mill. A mill for grinding grapes for must or apples for cider. (See CIDER-MILL.) The example shows a pair of studded grinding rollers, an apron

Fig. 2115.



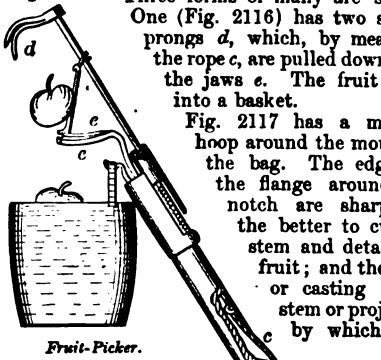


Fruit-Mill.

on to which the fruit falls and is carried between several consecutive pairs of rollers, which express the juice.

Fruit-pick'er. An implement for reaching up to and picking fruit from a tree. Three forms of many are shown. One (Fig. 2116) has two sliding prongs *d*, which, by means of the rope *c*, are pulled down upon the jaws *e*. The fruit drops into a basket.

Fig. 2116.



Fruit-Picker.

Fig. 2117 has a metallic hoop around the mouth of the bag. The edges of the flange around the notch are sharpened, the better to cut the stem and detach the fruit; and the band or casting has a stem or projection by which it is attached at an angle to the handle.

In Fig. 2118 a vertical blade is fixed to the end of the handle, and against this blade another is caused to work like a pair

Digitized by Google

of shears, the movable blade being operated by a cord and spring. The stem of the fruit is cut, the fruit falling into a pocket attached to the top of the pole.

Fig. 2117.

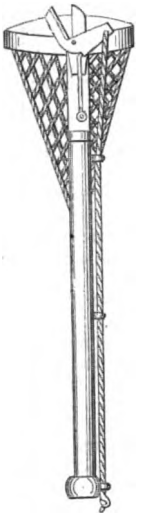


Fig. 2118.

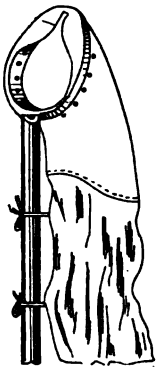
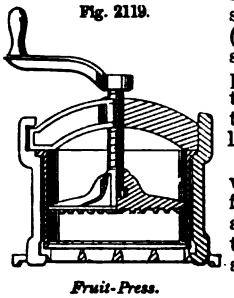


Fruit-Pickers.

Fruit-press. One for expressing the juice of fruit. The subject is considered under CIDER-PRESS (which see). The example shows a small domestic press for fruit, such as those used in limited quantities for currant-wine, jellies, etc.

Fig. 2119.



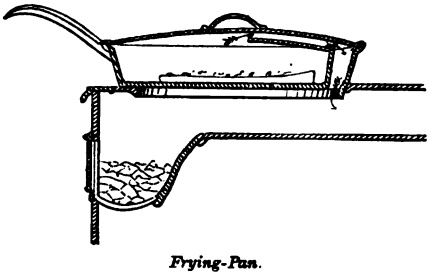
Fruit-Press.

Fry'ing-pan. A pan in which food is cooked in fat. In the illustration, a duct leads the fumes of the cooking down into the stove-flue.

Fudge-wheel. (*Shoemaking.*) A tool to ornament the edge of a sole.

Fu'el, Ar'ti-fi'cial. Agglomerated peat, sawdust, coal-dust, and slack, one or more of them in various combinations, bound together, by heavy pressure, with cements, clay, coal-tar, or the residuüm of

Fig. 2120



Frying-Pan.

starch-manufacture. The latter is used in the Belgian and Austrian works. Dehaynin's works in Belgium turn out 175,000 tons of this fuel per year. It leaves six per cent of ashes. The Northern Railway of Austria has works which produce 15,000 tons per annum; prisms $9 \times 5 \times 4\frac{1}{2}$ inches, weighing eight pounds, evaporating seven pounds of water per pound of fuel. The coal is compressed with the refuse of starch-works as a cement, and dried in a kiln heated overhead by a current of hot air.

Small coal two parts and clay one part, molded into blocks like cannon-balls and dried, have been used for a century past in Hainault. — *London Monthly Magazine*, April 1, 1800.

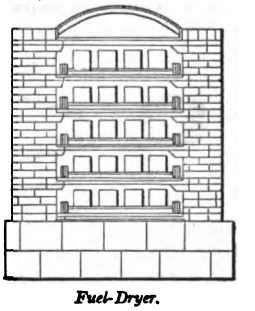
Peat and turf cut into blocks and dried have been used any time these thousands of years past, but the business of preparing peat-fuel by mechanical means and by admixtures is comparatively modern. (See PEAT-MACHINE.) In 1603 Sir Hugh Platt published a book in which he described a new fuel block made of coal and loam in "the manner of Lukeland of Germanie." He also used coal-slack, sawdust, tanner's bark, aggregated by loam and cow-dung. Chabanne's English patent of 1799 claimed separating the large coal from the small coal by passing the latter through sieves or gratings made of wood or metal, and then consolidating the small coal by mixing it with earth, clay, cow-dung, tar, pitch, broken glass, sulphur, sawdust, oil-cakes, tan, or wood, or any other combustible ingredient, to be mixed together and ground with a wheel in water, in a wooden vessel; this mixture he afterwards placed in pits provided with drains for the water to run off, and then, when dry, molded the mass into cakes of a considerable size.

The following United States patents may be consulted: —

13,056	1855.	44,262	1864.
15,688	1856.	44,940	1864.
26,541	1859.	47,296	1865.
35,472	1862.	50,588	1865.
40,753	1863.	51,833	1866.
40,791	1863.	53,431	1866.
40,920	1863.	55,369	1866.
42,163	1864.	61,006	1867.
43,112	1864.		

Fuel-dry'er. A kiln for drying blocks of artificial fuel. The trays supporting the blocks of fuel run upon rollers upon the angle-iron bars secured in the walls. The walls have perforations to allow the escape of the vapors resulting from the drying of the blocks. Either heated air or steam-pipes may be placed between the trays. The ends of the chamber may be closed by metallic doors.

Fig 2121.



Fuel-Dryer.

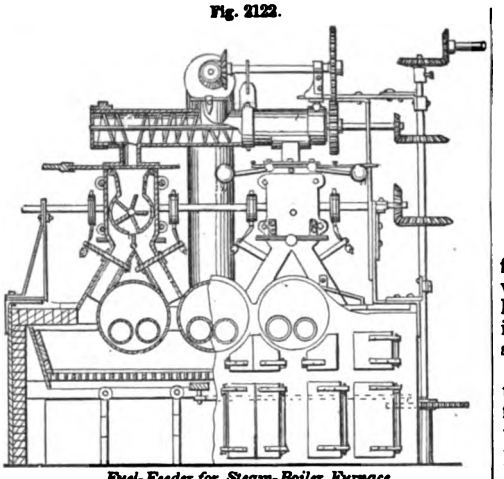
Fu'el-feed'er. A device for feeding fuel in graduated quantities to a furnace, either for metallurgical purposes or for steam-boilers. The example shows an apparatus for carrying coal, sawdust, and other fuel, from a bunker to the furnace, and feeding it regularly and evenly upon the grate under the boilers. It is worked by the engine. It will be readily understood without specific description. James Watt, 1769, and some even before him, tried to feed furnaces mechanically to save fuel. Some of the devices are noted under SMOKE-CONSUMING FURNACE (which see).

Fu'el Press, Com-pressed'. A machine for compressing coal-dust and a cementing material into a block.

In one form the material is forced within cylindri-

Digitized by Google

Fig. 2122.



Fuel-Feeder for Steam-Boiler Furnace.

cal pipes of cast-iron by the resistance offered to its passage through the pipe, and caused by the friction of the material against the sides of the pipe. The compressed fuel passes out of these cast-iron pipes, as a continuous cylindrical bar, which is broken in suitable lengths, and sold in the form of round logs.

Mazeline's machine produces bricks of prismatic form. It consists of a mixing apparatus, which feeds the material into a machine, having twelve square molds arranged in a circular frame, which has a rotating movement. Each die is worked by a square piston projecting into it from the bottom, and acted upon by an inclined plane which presses the pistons upward during the revolution of the circular frame, so that each brick is completed and delivered by the respective mold, making one complete turn round the central axis of the machine. See PEAT-MACHINE.

Ful'crum. A prop or support; the point on which a lever turns.

Ful'crum For'ceps. A dentist's instrument in which one beak is furnished with a hinged plate

Fig. 2123.

Fulcrum-Forceps.

which bears against one side of the object, while the other beak has the usual tooth or gouge shape.

The plate is covered with an india-rubber pad or cushion about $\frac{1}{8}$ of an inch thick, secured by fine wire. The pad rests on the gum.

Ful'gu-ra'tion. (*Metallurgy.*) The sudden brightening of gold or silver in the crucible as the last traces of dross leave the surface.

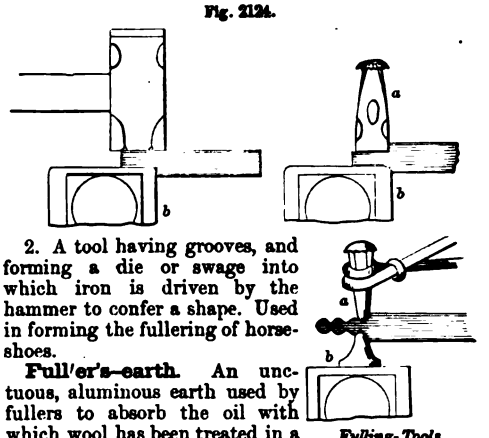
Full-bound. (*Bookbinding.*) Covered with leather.

Full-cen'ter Arch. A semicircular arch or vault. One describing the full amount of 180°.

Full'er. (*Forging.*) 1. A tool, sometimes known as a *creaser*, struck by the hammer or placed in the hardy hole of the anvil and employed to swage down or spread the iron by a series of parallel indentations.

The tools are known respectively as the *top* (*a*) and *bottom fuller* (*b*).

Fig. 2124.



Fulling-Tools.

2. A tool having grooves, and forming a die or swage into which iron is driven by the hammer to confer a shape. Used in forming the fullering of horse-shoes.

Full'er's-earth. An unctuous, aluminous earth used by fullers to absorb the oil with which wool has been treated in a previous part of its manufacture.

Full'ing. A process by which cloth made of a felting fiber is condensed, strengthened, and thickened, with a loss of width and length. Some fibers will felt, others will not. (See FELT.) In felting, the fibers — wool, for instance — slip past each other, and their toothed edges interlock, so that a continuation of the process causes them to be more and more intimately associated, huddling together and holding tight.

The cloth is folded or rolled, and treated with soapy water. It is then beaten with wooden stocks or mallets, by which the serrated edges are forced past each other and the fibers closely commingled. Precautions are taken in some cases to prevent adherence of the folds of cloth by felting together. For this purpose cotton cloth may intervene between the folds of woolen cloth in the roll. It is usually folded, however.

Fulling and felting are dependent upon the same principle of action. Felted cloth is made by this process of associating the fibers, and is not woven. Woven cloth exposed to the fulling or felting action is said to be *milled*. Repetition of the process constitutes it *double-milled* or *treble-milled*, as the case may be. Each milling thickens and solidifies it, while diminishing the area.

In a tomb at Beni Hassan about the time of Osirtasen, who was probably the Pharoah that invited Jacob to Egypt and settled him in Goshen, we find a representation of the fulling process (shown at *a*, Fig. 2125). The roll of cloth is wetted and worked between a block and the inclined table, the water running into a trough below.

After this record of the eighteenth century B. C., it is easy to discredit the statement of Pliny that the art of scouring and fulling cloth and woolen stuffs was invented by Nicras, the son of Hermias, who was a governor of Megæra under Augustus. The Romans worked the cloth with lye and fuller's earth, then washed it in a decoction of saponaceous plants, and then bleached it by fumigation with sulphur.

The instruments of the fuller are mentioned by the Greek authors. One form is a pounder, and the other a wooden roller.

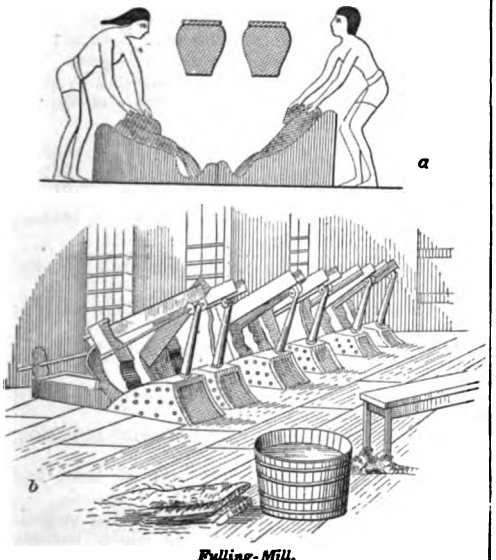
The operations of fulling are shown in the paintings on the walls of Pompeii. At that time the fullers were also the washers of ordinary clothes.

"The largest and best executed paintings representative of the art were discovered in 1820, in the house of a fuller opening on one side on the street of Mercury, and on the other on a street called after

Digitized by Google

him, Fullonica. In the court, a pillar covered with pictures was standing alongside a fountain. This pillar has been removed and deposited in the Naples Museum. In the lowest division, a woman, sitting, hands a piece of cloth to a little female slave. A workman, whose tunic is closely tied around the body, is looking at them while at the same time carding a white cloak with a purple border, suspended from a stick. Another workman is in the act of sitting down alongside a crate of wicker-work on which the cloth is to be spread out; in one hand he holds a vase, on which sulphur thrown on burning charcoal will develop a gas capable of bleaching the cloth. This is the same method which is used to-day. On another face of the pillar arched niches contain large vats where the goods are soaked. Slaves standing in those vats trample the fabric with their bare feet in the same manner as Arabian women wash their clothes by trampling them against the rocky bed of a stream; this is what the ancients called "the fuller's dance" (*saltus fullonicus*). The artist has painted with the same care the press with its two uprights, its two enormous screws, which were turned by means

Fig. 2125.



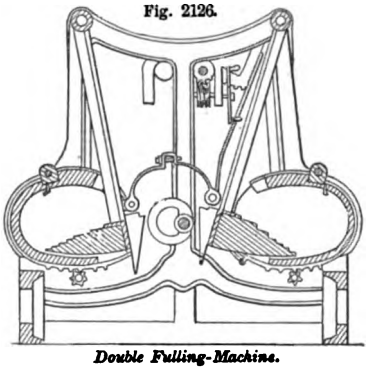
Fulling-Mill.

of cranks, in order to flatten the cloth beneath the planks, which imparted the necessary finish. Finally, the drying-chamber is shown by long sticks hanging on chains from the ceiling. The linen is spread out on them; a slave hands to a young woman an open fabric, while the wife of the fuller makes a note of it on her tablets. I have visited with particular curiosity the houses in Pompeii where these pictures had been gathered. I counted there in a court twenty-two tanks constructed of stone, and at different levels, so that the water could run from one into the other. Little benches in front of them served for the reception of the goods. At the other end of the court, seven smaller tanks served for fulling. The store-room, with traces of the planks, which were laid like rays radiating from a center, the hearths, the drying-chamber, may still be recognized. In other fullers' establishments I have seen very thick sheet-lead lining the interior of vats made of cement. Sometimes, also, we find jars full of greasy earth, which must be the fuller's earth of which Pliny speaks, and which contributed as much to the whiteness of the goods as the fumigation with sulphur." — M. Beulé.

The modern fulling-mill *b* consists of an iron framework supporting the shanks of heavy wooden mallets, which are raised by projecting cams on a tappet wheel. The mallets being raised to their full hight are released, and drop by gravity on the cloth, which is contained in an iron trough beneath. Soap is added as a detergent, grease in any form tending to mar the felting action of the fibers. The end of the trough is curved, so that the cloth is turned round and round by the action of the mallets.

Fig. 2126 is a vertical section of a double mill in which a spring or weight forces the tub up to the

Fig. 2126.

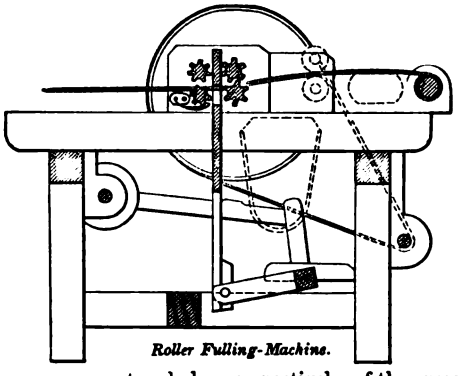


Double Fulling-Machine.

beaters with a yielding pressure, rendering the tub capable of adjusting itself to a larger or smaller quantity of goods. The beaters are arranged in pairs, each pair being connected together by springs and acted upon by a common eccentric.

In Fig. 2127 the felted cloth is held slack between two pairs of fluted rollers while a beater operates upon it. The variation in the velocity of the respective pairs of rollers is equal to the contraction of the cloth, which is damped and dried at the

Fig. 2127.



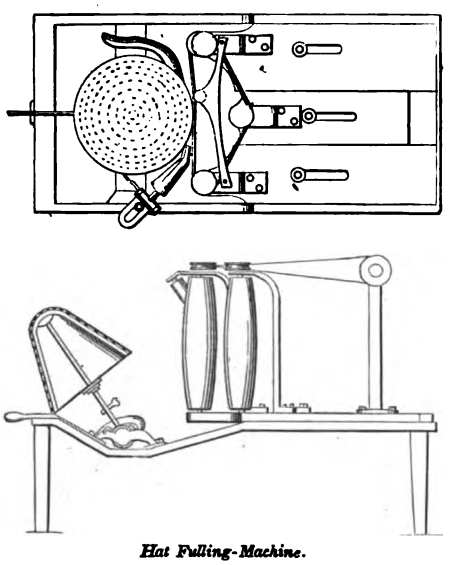
Roller Fulling-Machine.

commencement and close, respectively, of the operation.

Fig. 2128 shows a machine for fulling and felting hat bodies, in which the rollers carry around the apron, which, by contact, rotates the "form," and acts upon every portion of the perimeter of the hat body, the latter being saturated with water, which may be conducted through the tubular support of the form, and be diffused between the walls of the form, so as to escape outward. Owing to the eccentricity of one of the rollers, the apron is repeatedly stretched and relaxed, laterally, and in the act of

Digitized by Google

Fig. 2128.



Hat Fulling-Machine.

drawing narrower the apron produces a greater pressure upon the hat body, and has the effect to interlock and compact the fibers.

A *broad-cloth* having 3,600 threads in the warp, a width of 3$\frac{5}{16}$ yards, and a length of 54 yards, will be reduced in fulling to 1$\frac{3}{4}$ yards wide and 40 feet long. The process will take 60 to 65 hours, and require 11 pounds of soap.

A *Venetian* cloth will require about twelve hours, take from 6 to 7 pounds of soap, and will shrink in width from 1$\frac{1}{16}$ yards wide to 1$\frac{1}{8}$.

After fulling, the cloth is washed to remove the soap.

The method of fulling woolen goods in early times in Ohio is well described by Judge Johnston of Cincinnati, in his address before the Pioneer Society of that city, 1870.

KICKING BLANKETS.

"When wool became abundant, the method of scouring and fulling blankets, flannels, cassinets, and even cloths, was simple. Every house had hand-cards, and as many spinning-wheels as spinners, and no respectable house was without a loom. When the goods were carded, spun, and woven, then came the kicking frolic. Half a dozen young men, and a corresponding number of young women, "to make the balance true," were invited. The floor was cleared for action, and in the middle was a circle of six stout splint-bottomed chairs, connected by a cord to prevent recoil. On these sat six young men with shoes and stockings off and trousers rolled up above the knee. In the center the goods were placed, wetted with warm soapsuds, and then the kicking commenced by measured steps, driving the bundle of goods round and round; the elderly lady, with a long-necked gourd, pouring on more soapsuds, and every now and then, with spectacles on nose and yardstick in hand, measuring the goods till they were shrunk to the desired width, and then calling the young men to a dead halt.

"Then while the lads put on their hose and shoes, the lasses stript their arms above the elbows, rinsed and wrung out the blanket and flannels, and hung them on the garden fence to dry."

Full'ing-ma-chine'. A machine in which the operation of fulling cloth is performed. See FULLING.

Full'ing-mill. A common name for the fulling-machine. See FULLING.

Ful'mi-nate. Beckman states that fulminate of gold was discovered by a monk in the fifteenth century. This substance, which explodes more rapidly and with greater local force than gunpowder, is made by precipitating a solution of chloride of gold by an excess of ammonia. Mr. Forsyth discovered that by treating mercury as the old monk had treated gold, an equally powerful but far less expensive fulminate might be made. This he mixed with six times its weight of niter, and the result is the percussion-powder which, in the form of paste, is used for charging copper caps for fire-arms. In modern practice the proportion of niter has been much reduced.

"Dr. Allen tells me that something made of gold, which they call in chymistry *Aurum Fulminans*, a grain, I think he said, of it, put into a silver spoon and fired, will give a blow like a musquett, and strike a hole through the silver spoon." — PEPYS, 1663.

A fulminating powder which explodes when heated to 360° may be made of niter, 3 parts; dry carbonate of potash, 2 parts; sulphur, 1 part.

The following patents may be consulted by those desirous of ascertaining the ingredients of various patented fulminates: —

Guthrie	1834.	Boldt	1866.
Kling	1857.	Rand	1867.
Ruschaupt *et al.*	1862.	Goldmark	1867.
Lipps	1864.	Ruschaupt	1868.
Stockwell	1865.		

Fu'mi-ga'tor. An apparatus for applying smoke, gas, or perfume: —

1. To destroy insects or vermin in their holes, or upon clothing, trees, or plants.

2. To destroy infection or miasma in buildings, ships, clothing, or feathers.

3. To diffuse a fragrant or invigorating perfume through an apartment or ward.

4. To suffuse the lungs with a soothing or healing vapor.

The fumigator involves the use of heat, and generally that of an artificial blast.

1. A fumigator for expelling or killing animals usually consists of a chamber in which burning matters are placed, and a bellows by which a blast of air is driven through the retort, issuing with the fumes at a nozzle directed to the burrow or haunts of the vermin.

Sometimes powder is substituted for fumes.

2. Fumigators for destroying infection are sometimes only agents for making a stench which overpowers the precedent nuisance. The burning of tobacco, feathers, leather, brown paper, etc., will conceal, but does not remove, an unwholesome smell. More potent agents, such as pastiles, pepper, hot vinegar, etc., have been used as disinfectants with but small effect.

The effective agents in fumigating are sulphurous acid gas, chlorine, tar, roasting coffee, etc.

The ordinary disinfectant is chlorine, either in the form of chloride of lime or in the direct evolution of gas from a mixture of salt, manganese, suphuric acid, and water.

This was the plan adopted by Faraday in the disinfecting of a penitentiary in London. The space being about 2,000,000 cubic feet, he used 700 pounds of common salt and the same quantity of

Digitized by Google

black oxide of manganese. The mixture was set about in numerous pans throughout the wards and corridors. Three and a half pounds of a mixture of salt and manganese were placed in a pan, and on them was poured 4½ pounds of dilute acid. (Sulphuric acid, 2; water, 1.)

3. The perfuming fumigator is generally of the form of an ATOMIZER (which see).

4. As applied to the mouth it is an INHALER (which see).

Fum'ing-box. (*Photography.*) In printing photographically, the sensitive paper, having chloride and nitrate of silver upon its surface, is exposed to the fumes of ammonia immediately before its exposure to light under the negative; the object being to secure greater depth and brilliancy in the resulting print. The apparatus for this purpose is simply a tight box, in which the sensitive sheets can hang, leaving a space below them for a flat basin containing ammonia. Boxes of this kind are variously constructed, the object in all cases being to admit of the ready introduction and removal of the sheets, as well as of the vessel containing ammonia, without subjecting the operator to unnecessary annoyance from the fumes.

Fu-nic'u-lar-ma-chine'. One actuated by means of a cord whose ends are attached to two objects and which bears a weight suspended from the bight. Some double-toggle presses come within the terms of this description. The name is principally applied to instruments illustrative of mechanical principles, and having a rope, pulley, and suspended weights.

Fun'nel. 1. The chimney of a steamship. It is of sheet-iron, and is carried to a sufficient hight to assist the draft of the furnace.

It is made telescopic in war-vessels, so as to be lowered beyond the reach of shot.

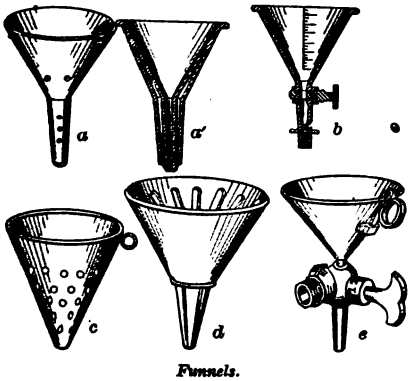
2. The pouring-hole of a mold. A *gate;* a *tedge.*

3. A conical vessel which terminates below in a spout, and used for conducting a liquid into a vessel which has a small opening.

An implement with a wide mouth and tapering spout, used for conducting liquids into a narrow-throated vessel.

a a' are elevations and sections of a funnel, which

Fig. 2129.



Funnels.

has a discharge around the spout for the air displaced by the liquid.

b is a graduated funnel, which indicates the quantity of the contents. See MEASURING-FUNNEL.

c is a pierced filter of porcelain or glass, used in a laboratory, with a cone of bibulous paper inside.

d is a filter of similar use, but with heavy ridges, to keep the paper from adhering to the sides.

e is a combined measure, faucet, and funnel.

The filter-funnel should have sides which subtend an angle of 60°, for the reason that a sheet of bibulous paper, folded quarterly and one flap opened, forms a cone the vertical section of which is a triangle with sides forming that angle.

Fun'ny. (*Nautical.*) A narrow, clinker-built pleasure-boat, to be rowed by a pair of sculls.

Fuor. (*Carpentry.*) A piece nailed upon a rafter to strengthen it when decayed.

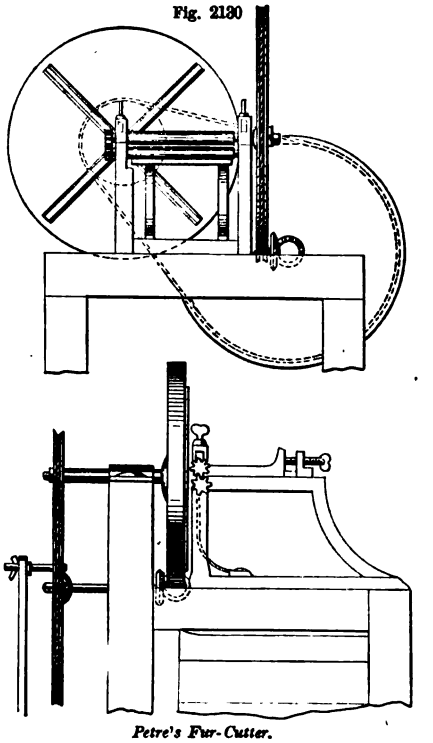
Fur'bish-er. A *burnisher.*

Fur-cut'ter. 1. A machine for cutting the fur from the skin.

Johnson, 1837, has a knife hinged at the end, and descending to make a shear cut against a stationary blade. The skin passes over a small roller, which displays the fur and enables the knife to reach the hairs near the roots, without to any great extent cutting to waste or cutting the same hairs twice.

Petre, 1827, has a pair of rollers, between which the skin passes. As the skin is bent over one of the rollers, the hairs are displayed and thus laid over a straight edge. The knives are fixed radially to a rotating disk, and shear past the straight-edge, sev-

Fig. 2130



Petre's Fur-Cutter.

ering the hairs with nearness to the skin determined by the *set* of the machine.

Williams, 1832, has a frame with a series of parallel knife-edges presented upwardly. Over them is a block carrying an oblique knife which makes a shear cut upon the fixed knives in succession.

Flint's fur-cutting knife, 1837, has an edge on one jaw and a cushion on the other.

See also Harlow's patent for cutting bristles, 1868.

2. A mechanical contrivance for shaving the backs

Digitized by Google

of peltry skins, to loosen the long, deeply rooted hairs, leaving the fine fur undisturbed.

Fur-dress'ing. Fur, in its usual trade acceptation, is the short, fine hair of certain animals, growing thick on the skin and deprived of the long, coarse, protecting hairs.

Furs are dressed by greasing and tramping, or by beating in a fulling-mill, the skin being softened by the absorption of grease and the mechanical treatment. They are then wetted, fleshed, curried, tramped in vats with sawdust, and again with whitening to remove the grease. They are then beaten with a stick and combed.

The term *dressing* includes the cleaning, cutting, and dyeing of furs. The long hair that covers the fur is removed by a process carried on in but few places successfully. The skins are placed on frames, and the inner surface pared off, until the roots of the *hair* are completely severed, while the roots of the *fur* remain untouched, on account of their nearness to the outside surface. The hair is then very easily removed, and the light yellow fur made ready for dyeing, either to a more golden yellow, a dark purple, or black, and is afterwards brought to the general fur-market.

In one process, the hair and skin are separated and a substitute for the skin applied to roots of the hair to retain them. Gelatine is applied in solution to the hair, so as to form, when cool, a body to hold the hair in position during the removal of the natural skin and the application of a substitute to the roots. The hair and natural skin are loosened by soaking in lime-water or other suitable means. The artificial skin may be formed of india-rubber, gutta-percha, or compounds thereof, boiled or drying oil, or other adhesive matters, strengthened, if desired, by woven fabrics, and when applied and set, the glutinous matter employed as temporary holding medium may be removed by dissolving in warm water or steam.

Furl. (*Nautical.*) To roll a sail and confine it to the yard.

The sail being gathered by the men on the yard, the *leech* is passed along the yard to the *bunt*, where the body of the sail, the *foot* and *clews*, are collected.

Cunningham's patent (English) mode of setting and furling sails is, by rolling the yard by means of ropes from the deck, unwinding or winding the sail, as the case may be. The plan involves a vertical division of the sail, and has not come into general use.

Furl'ing. The wrapping or rolling of a sail on a yard or boom and securing it.

Fur'nace. A chamber in which fuel is burned for the production of heat, which is directed upon an object in the vicinity, such as an ore or metal under treatment, a steam-boiler, an air-heating chamber, a glass-pot, or what not.

Furnaces are distinguished by construction, by mode of operation, and by purpose. See under the following heads: —

Fur'nace-bridge. A barrier of fire-bricks or of iron plates containing water thrown across the furnace at the extreme end of the fire-bars, to prevent the fuel being carried into the flues, and to quicken the draft by contracting the area.

Fur'nace-grate. The bars supporting the fuel in a furnace. See GRATE.

Fur'nace-hoist. An elevator for raising the ore, lime, and coal to the mouth of a blast-furnace. These are of several different forms; the example shown is on the pneumatic principle. It consists of a central tube *a* in which is a heavy piston *b*,

Digitized by Google

which forms a counterweight for the platform *c*, which works against guides on the outside of the tube. The piston is lightly packed by cotton gaskets, and is connected to the platform by four wire-ropes, two of which only appear in the vertical sectional view.

The hoist is worked by an engine with a pair of inclined cylinders, operating a pair of single-acting air-pumps, which can be made to compress air into or exhaust air from the space in the tube below the piston. Supposing the empty table with the empty barrows to be at the top, and the piston at the bottom of the cylinder, the air-pumps are connected with the latter so as to deliver air into it, and thus lift the piston, a pressure of about two pounds per square inch being sufficient to do this. On the other hand, if the table is at the bottom of its travel and loaded, the exhausting side of the air-pump is, by means of the reversing slide, placed in communication with the cylinder, and a partial vacuum produced under the piston. If the table be loaded with the heavy iron-stone wagons, carrying about 5,000 pounds of stone, there is a weight of about 4,000 pounds left unbalanced, and exhaustion of about 4 pounds per square inch is required to bring the piston down, while, with the coke-barrows, weighing only 2,000 pounds, there is but about 1,000 pounds of unbalanced load, and the piston is brought down and the table raised by a vacuum of about one pound only.

Fur'ni-ture. 1. (*Nautical.*) The masts and rigging of a ship.

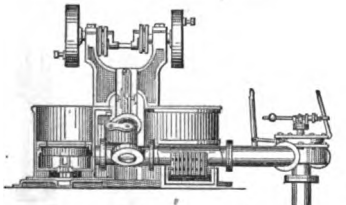
2. The mountings of a gun.

3. Builders' hardware, such as locks, door and window trimmings, etc.

4. Movable articles of use and decoration in a house.

The ancient Egyptians excelled in furniture, chairs with arms and backs magnificently upholstered, with seats like our rush-bottoms, or folding like our camp-stools.

Their bedsteads were couches, generally designed for one person, and variously ornamented. Some have legs representing those of men or of dogs, the bed portion being a ridiculously attenuated body to correspond. See CHAIR; BEDSTEAD, etc.



Their tables were round, square, oblong; of wood, stone, metal; carved, painted, gilded; with a central column or with several legs.

5. (*Printing.*) The wooden inclosing strips and *quoins* which surround the *matter* in the *chase*.

The pieces are about half an inch high, of various lengths. The strips are called *head*, *foot*, or *side sticks*, according to their position in the *chase*.

Strips between the pages are *gutters*.

The *sticks* are slightly tapering, so as to allow the wedge-shaped *quoins* to jam the matter firmly together in the *chase*.

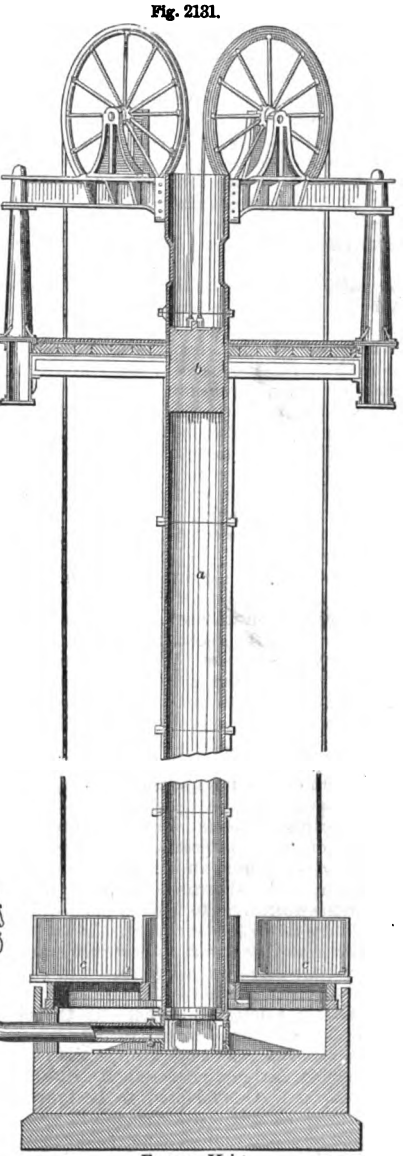
The *quoins* are driven by the *shooting-stick* and a mallet.

Fur'ni-ture-pad. A piece of india-rubber or similar thing attached to a piece of furniture to prevent rubbing or striking against objects.

Fur'ni-ture-spring. A coiled spring beneath the hair filling which forms the seat, back, or side of a cushioned chair. A spring of a bed-bottom beneath a mattress, or forming the lower portion of one beneath the elastic material which constitutes the top.

Fur'ni-ture-tip. An india-rubber disk placed on the foot of a chair-leg, to enable the chair to be moved and replaced noiselessly upon bare boards or marble floors.

Fig. 2131.



Furnace-Hoist.

Fur-puller. The fine fur of fur-bearing animals is protected by a coat of long, straight hairs, which is removed before the fine hair is sheared off to furnish the material for felt.

This operation, formerly effected by hand, is now performed by machines. The skin is passed around the projecting edge of a bed, the tension of the skin being maintained by weights. As the skin is drawn forward over the projecting edge of the bed, the long hairs stand out nearly at right angles, and are seized

Digitized by Google

and extracted by ribs on a pair of revolving cylinders which are placed in front of the bed.

Graham's machine, 1835, passes the skin between two feed-rollers over a third higher roller, which spreads the hairs, which are pinched between a revolving blade and the elastic surface of a leather-covered cylinder, and so pulled out of the skin, which is stretched and fed by two pairs of rollers between which it passes.

Fur'ring. 1. Fixed thin pieces on the edge of timber to make the surface even.

2. Double planking of a ship's side.

3. The scaly deposit on the inside of a boiler.

4. A lining of scantling and plaster-work on a brick wall, to prevent the dampness of the latter reaching the room.

Fur'row. 1. (*Agriculture.*) The trench made by a plow.

2. (*Milling.*) The grooves in the face of a mill-stone; the plane surface is *land*.

A *leader-furrow* extends from the eye to the skirt of the stone at such *draft* as may be determined. The draft is the degree of deflection from a radial direction. In a seven-inch draft the track edges are tangential to a seven-inch circle around the eye of the stone. The steep edge of the furrow is called the *track*-edge; the more inclined edge is called the *feather*-edge.

The *second furrow* is that branching from the leader nearest to the eye.

The *skirt-furrow* departs from the leader nearer to the skirt.

A *gouge-furrow* is concave at bottom. See MILL-STONE.

Fur'row-ing-ham'mer. A mill-stone dresser's hammer. See MILL-STONE HAMMER.

Fur'row-ing-plow. One with a double mold-board for throwing the earth both ways.

Fu'sa-role. (*Architecture.*) A molding or ornament placed immediately under the echinus in the Doric, Ionic, and composite capitals.

Fuse. A tube or casing filled with combustible material, and used for igniting a charge in a mine or hollow projectile.

The invention was undoubtedly contemporaneous with that of hollow projectiles.

Blasting-fuse; used in mining and quarrying is filled with a slow-burning composition, allowing time for the operatives to reach a place of safety before it burns down to the charge.

Combination-fuse; for hollow projectiles, comprises a time-fuse and a percussion or concussion-fuse united in the same case.

The former is designed to explode the charge in case the latter fails to act on striking.

Concussion-fuse; for hollow projectiles. Designed to explode the charge when the shell strikes an object.

Electric-fuse. One adapted to be ignited by the passage of an electric spark through it.

Percussion-fuse; embraces a capsule charged with fulminate, which is exploded by a plunger or its equivalent, when the projectile strikes. The plunger is held by a pin sufficiently strong to keep it in place in case of a fall, yet weak enough to be severed by the shock of striking.

Safety-fuse; a cord or ribbon-shaped fuse filled with a fulminating or quick-burning composition, and sufficiently long to be ignited at a safe distance from the chamber where the charge is placed.

Tape-fuse; belongs to the class just mentioned, and is so called from its shape.

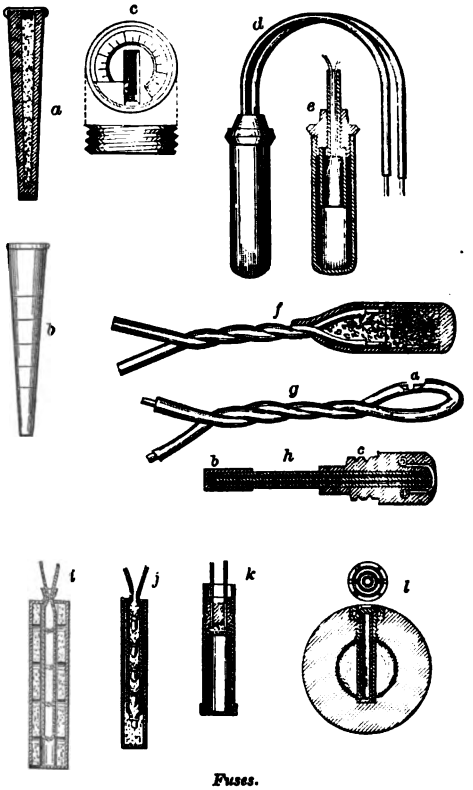
Time-fuse; one which is adapted either by cutting off a portion of its length or by the character of its composition to burn a certain definite time.

Fig. 2132, *a b* is the common wooden fuse for shells; the central cavity is filled with a composition of niter sulphur and mealed powder thoroughly incorporated together, and uniformly and compactly driven by means of a mallet and drift. The open end is capped with water-proof paper or parchment.

For use, a part is sawed off at the smaller end. The number of seconds which the remaining composition will burn is indicated by the annular lines, so that cutting off a greater or less portion regulates the time of bursting of the shell. The fuse is inserted in the fuse-hole when the projectile is required for use, and the cap removed previous to loading the piece.

Paper fuses containing compositions which burned at the rate of two, three, four, and five seconds to

Fig. 2132.



Fuses.

the inch were formerly employed for field artillery in the United States service. A wooden fuse-plug was driven into the projectile when prepared for service, and the fuse inserted therein at the moment of loading. The different kinds were indicated by their color.

These were succeeded by the Bormann fuse *c*, which consists of a flat, circular, screw-threaded piece of an alloy composed of equal parts of tin and lead, having a deep annular channel extending nearly around its lower surface, into which the fuse composition is pressed, communicating with a magazine of fine powder. The composition is protected by an annular piece of the same metal, which is forced down over it by pressure, and turned to a smooth surface. The upper part of the fuse is graduated to quarter-seconds up to five seconds, so

Digitized by Google

that by removing the thin metal covering with a small gouge at any particular mark, the composition, when ignited, will burn the length of time that the mark indicates before reaching the magazine which communicates fire to the bursting charge of the projectile. This fuse rests in part on the walls of the shell and in part on a perforated iron fuse-plug, set in a smaller orifice central to the exterior fuse-hole. When screwed in, it is cemented to the shell by white lead ground in oil, rendering its extraction somewhat difficult and dangerous. To obviate this a modification has been contrived consisting of a flat ring which contains the composition inserted into an annular groove surrounding the hole through which powder is poured into the shell. As this may be made smaller than the ordinary fuse-hole, the efficacy of the bursting charge for shattering the shell is increased, while the charge may be removed without disturbing the fuse; thus greatly lessening the danger of accidents, when it is desired to remove the powder. This form also admits of longer burning fuses than the original Bormann.

Brass fuses having a crooked channel to prevent the entrance of water between the exterior priming and the fuse composition are also employed, more particularly in the naval service.

The English Boxer fuse has a main channel for the fuse-composition, and two smaller channels filled with mealed powder communicating therewith and with each other. Holes corresponding to the lengths required to burn various times are bored from the exterior of the fuse-case to these, and filled with pipe-clay, which is removed from the proper hole when the projectile is inserted into the gun.

Powel's fuse *l* (Fig. 2132) admits of being turned within the plug, which is screwed into the shell so as to bring corresponding apertures in the fuse and the plug into communication. These are so adjusted to each other that the composition may be made to fire the bursting charge at the expiration of a greater or less number of seconds.

Fuses on this principle have been combined with the percussion-fuse, constituting the *combination* fuse.

Previous to the introduction of rifled cannon and elongated projectiles, a number of attempts had been made to produce a fuse adapted to spherical projectiles which would explode on striking.

One of these, of Prussian origin, was composed of a glass case containing strong sulphuric acid, and wrapped with cotton wick soaked in a composition of chlorate of potash and flowers of sulphur, with pulverized white sugar and alcohol added to give consistency. This was capped with a leaden breaker, which projected beyond a paper case in which the tube and wrapper were enclosed, and the whole inserted within a fuse-case partially filled with hard driven mealed powder. This was ignited on firing, and soon burned away, leaving the glass tube unprotected, so that the weight of the breaker would cause it to be shattered on striking an object, setting fire to the wrapper, which in turn exploded the bursting charge.

Splingard's Belgian concussion fuse contained a conical tube of plaster of paris closed at top surrounded by ordinary fuse-composition, which in burning left the tube unsupported, allowing it to break when striking, so that the fire should communicate directly with the charge.

Fuses which explode by percussion or concussion present no difficulty when employed with elongated projectiles for rifled guns, which strike point foremost; and a variety of such, differing slightly in details of construction, have been successfully employed.

Bickford's fuse, English patent, 1831, was specially intended for miners' use.

It consists of a cylinder of gunpowder or other explosive matter covered by a double layer of cord and varnished. A similar fuse covered with a waterproof composition was designed for submarine blasting.

In electric fuses the heat necessary to fire the charge is imparted either by the passage of the current through a fine wire, usually platinum, or through a chemical mixture rendered conducting by containing a salt of copper. *f* illustrates one of the former, in which the gutta-percha covering is removed from the ends of the conducting wires, which are connected by a fine wire of platinum; these, with the charge of fine grained powder, are enclosed in a water-tight envelope of gutta-percha. *g* is one of the second class, known as Statham's. Its operation depends on the fact that a copper wire covered for some time with vulcanized rubber becomes coated with a layer of sulphide of copper, which is a moderately good electric conductor. This is utilized by twisting a piece of rubber-covered wire so as to form a loop, when part of the covering is removed as shown at *a*, and the wire severed. Consequently, when a spark is passed along the wire, on reaching this spot it must follow the film of sulphide adhering to the rubber; and the resistance which it has to overcome causes the sulphide to ignite.

i j k illustrate Shaffner's blasting fuses and cartridges. *i*, a hollow cartridge provided with central and diverging spaces occupied by a series of fuses and loose nitro-cotton, the whole covered with a water-proof casing into which the ends of the conducting wires pass.

j. The main wires which pass to the mine or cartridge are connected by smaller wires to the fuses, a number of which are placed in a single charge of explosive material.

k is provided with a wooden head enclosed in an indented cylinder closed by a cap; the head has a recess for the fuse composition, and another for the non-conducting cement which surrounds the wires where they enter the head.

h is the Abel fuse. This consists of a wooden head having a central longitudinal opening and two parallel transverse ones. Through the former two insulated conducting wires are passed, the ends *b* of each being cut off smooth at some distance from the head, and covered with a tin-foil cap containing priming. The gutta-percha is removed from the other ends of the wires, and they are inserted and secured in the two transverse holes before mentioned. When required for use, a case containing fine grained powder is fitted over the shoulder *c* and secured by twine.

Bishop's electric fuse *d e* comprises an inner and outer cylinder protected by a perforated cap through which the separately insulated conducting wires pass.

Fuse-cut'ter. An implement for gaging time-fuses to the desired seconds and fractions. The Bormann, or metal-fuse cutter, is merely a small gouge, about one tenth of an inch in width across the blade, and is used for cutting away the thin shell of metal which overlies the fuse-composition. The cutter for paper fuses for rifled guns, which necessarily are required to burn much longer, is more usually called a fuse-gage. It is a block of wood with a graduated brass gage let into one side, and having a hinged knife working on the same side, like a tobacco-knife, by which the fuse, which is

Digitized by Google

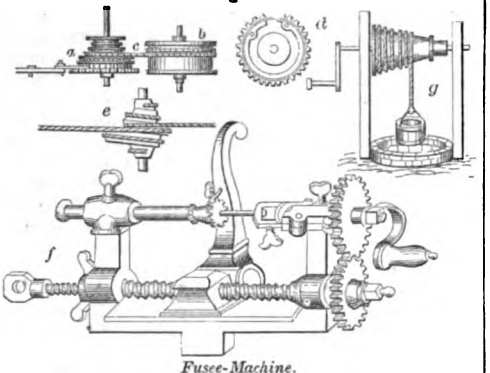
marked on the side to seconds and fractions, is cut off so as to burn any required length of time.

Fu-see'. 1. A conical pulley *a* used in connection with a spring, and designed to equalize the power of the latter. The spring is coiled within the barrel *b*, and when fully wound up and at its greatest tension the chain *c* is wound upon the fusee and draws upon its smaller portion. As the fusee unwinds, by the motion of the train of gearing in the watch, the spring also uncoils and loses a part of its tension; as this proceeds, the chain draws upon a larger portion of the fusee, and attains an increased leverage on the latter to counterbalance the decreased power of the spring. The object is to obtain an equal power at all times, so that the watch may run regularly.

The *first* wheel of a watch is attached to the *fusee*.

The *going-fusee*, invented by Harrison to continue the motion of the watch while it is being wound up, has an auxiliary spring *d* through which the power of the mainspring is communicated to the wheels. While the watch is being wound, a ratchet and click prevent the reaction of the auxiliary spring, which

Fig. 2133



Fusee-Machine.

acts during the time of winding, although the power of the mainspring is removed. The chain connecting the *barrel* and *fusee* has hooks at each end; in winding, the chain is wound off the former on to the latter. The *fusee* cannot be introduced into very flat watches, and the first wheel, in that case, is attached to the *barrel*. The latter is then called a *going-barrel*, having teeth cut on its sides.

A double fusee (*e*) to communicate a variable reciprocating motion is used in Roberts's self-acting mule.

2. A cigar-lighter made of cardboard impregnated with niter and tipped with a composition which ignites by friction.

3. A *fuse*.

4. A light firelock or musket. The name is antiquated. A *fusil*.

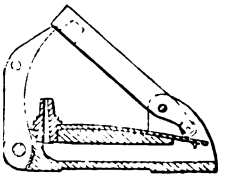
Fu-see'-ma-chine'. A machine (Fig. 2133) for cutting the snail-shaped or spirally grooved wheel on which the chains of certain descriptions of watches are wound. It was invented by the renowned Dr. Hooke about 1655. The machine (*f*) shown is the form that was used in 1741, and illustrates the idea thoroughly. It is also interesting as being the first machine in which *change-wheels* were used, and is the germ of the screw-cutting lathe. — THIRION, 4to, Paris, 1741.

Fu-see'-wind'lass. A pump-windlass with a conical barrel (*g*, Fig. 2133).

Fuse-ex-tract'or. This implement is designed for extracting wooden fuses from shells. It has jaws which grasp the fuse while the lower part of the extractor rests upon the shell. The jaws are attached to a screw, which works in a screw-socket in the body of the extractor, and has an iron lever passing through its head. The jaws being clasped around the projecting part of the fuse, it is drawn by turning the lever.

Fuse-lock. For miners.

Fig. 2134.

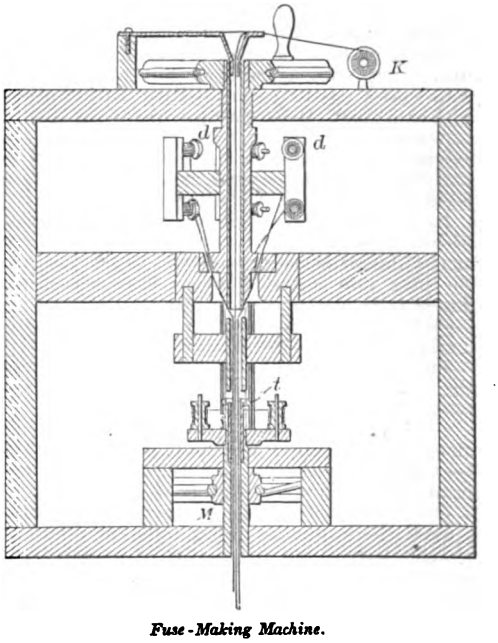


Fuse-Lock.

A spur on the spring attaches the lock to the fuse when the hammer is set. The dog is pulled by a long cord from a distant position of safety, releasing the hammer, which explodes the cap and lights the fuse.

Fuse-mak'ing. A machine having a vertical rotary shaft through which the powder descends around a central cord delivered from the spool *K*. Threads from the spools *d d*, etc., placed on a rotating frame, are wound about it as it descends, forming a twofold covering, which is compacted around the composition as the fuse passes

Fig. 2135.



Fuse-Making Machine.

through the ring *t* at the upper part of the slotted shaft *M*.

Fuse-saw. A tenon-saw used by artillery-men.

Fuse-set'ter. An implement for driving home wooden fuses. It consists merely of a cylinder of wood or brass, with a recess at the end fitting the end of the fuse, which is driven into place by a mallet.

Fuse-tape. A flat form of fuse, coated externally with pitch or tar, and *served* to prevent the coating from cracking, or covered with two warps and an interposed lap of cotton. Other forms might be noticed.

Fu'si-ble-al-loy'. An alloy, usually of lead, tin, and bismuth, compounded in such definite proportions as to melt at a given temperature.

Used as plugs in steam-boilers, so as to melt when

Digitized by Google

a certain pressure and heat is attained and allow steam to escape. See ALLOY, p. 62.

Fu'si-ble-plug. One placed in the skin of a steam-boiler, so as to be melted and allow the discharge of the contents when a dangerous heat is reached. See "Le Dictionnaire de Industrie, Manufac., Commerc., et Agricole." Par A. Baudrimar. Blanque aine et autres. Paris, 1833. Vol. I. p. 326.

Fu'si-ble-por'ce-lain. A silicate of alumina and soda obtained from cryolite and sand, fused and worked as glass.

Cryolite is a mineral consisting of fluoride of aluminium and sodium. It is found in great abundance and purity in Greenland, and serves to make a fine milk-glass, which is called fusible porcelain. It is known in Bohemia and Silesia as milk-glass. One part of cryolite is mixed with two to four parts of quartz or pure sand, thus being a silicate of alumina and soda, containing some fluorine that has not been dissipated during the melting process. The material is easily wrought into any form, and may be readily ground and polished. It is stronger than common glass, and is said to withstand the fire better.

Fu'sil. A light fire-arm or musket of an antiquated pattern.

Fust. The shaft of a column from the astragal to the capital.

Fus'tian. (*Fabric.*) *a.* A heavy woolen cloth with a napped surface for men's wear.

b. A coarse, thick, twilled cotton stuff for men's wear, and generally of a dark color. The plain, common fustian is specifically known as *pillow*-fustian; other varieties of fustian are known by the names of *corduroy, velverett, velveteen, thickset, double-jean, velvet-tuft, molcskin* (cropped before dyeing), *beaverteen* (cropped after dyeing), *cantoon.*

These goods were first made in Norwich, England, in 1554, and were called "Norwich satins."

Fut'chel. (*Carriage.*) The jaws between which the hinder end of a tongue is inserted; the similar parts in a wagon are called tongue-hounds.

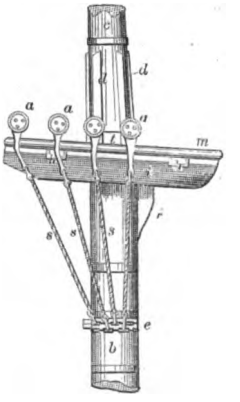
Fut'tock. (*Shipwrighting.*) One of the timbers in the compound rib of a vessel. A timber of the dimensions and form for the rib of a vessel cannot be procured in one piece; the rib is built up of pieces scarfed together. The number is according to the length of the sections of the requisite hight. They are known as the *first, second,* and *third futtock,* terminated by the *top-timber.* See FRAME.

Fut'tock-hoop. (*Nautical.*) A hoop encircling the mast at a point below the head, and serving for the attachment of the shackles of the futtock-shrouds. See Fig. 2136.

Fut'tock-plank. (*Shipbuilding.*) The first plank of the *ceiling* next to the *keelson.* The *limber-strake.* The first plank of the *skin* next to the *keel* is the *garboard-strake.*

Fut'tock-plate. (*Nautical.*) An iron plate on the edge of the *top,* to which the *futtock-shrouds* and the *dead-eyes* of the topmast *shrouds* are secured.

Fig. 2136.



Futtock Plate and Shrouds.

s s, futtock-shrouds.
b, lower mast.
e, futtock-hoop.
a, dead-eyes.
c, topmast.
d, mast-battens.
h, cross-trees.
i, trestle-tree.
m, futtock-plate.
r, cheek or hound.
t, bolster.

Fut'tock-shrouds. (*Nautical.*) The short *shrouds* attached to the *chain-necklaces* on the mast, and to the sides of the top, by which ascent is had from the principal shrouds to the top. See Fig. 2136.

Fyke. A bag-net, open to allow fish to enter, but opposing their exit.

Digitized by Google

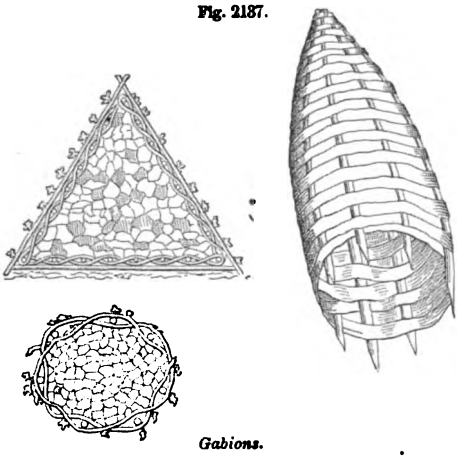
G.

Gab. The hook on an eccentric-rod which engages the wrist on the rock-shaft lever of a valve-motion. The word *gab* means *mouth* in several languages, and the term signifies that it is open to *bite* upon that placed within it. See GAB-LIFTER.

Gab'ar-age. (*Fabric.*) A coarse linen packing-cloth.

Ga'bi-on. A long basket of osiers or withes. When filled with earth, they are adapted to revet

Fig. 2137.



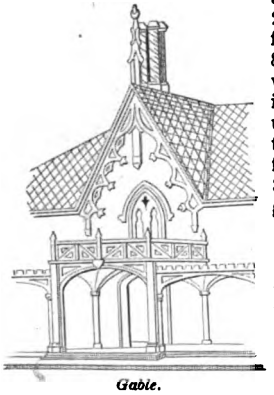
Gabions.

parapets and embrasures of fortifications. They are also used in other earthworks, such as batteries or rifle-pits.

Gabions filled with stones are used in civil engineering as defences for *starlings* of bridges; for making *dikes* or river-walls, where the shore is subject to washing; for making isolated islands, or chains of such, off shore, as a breakwater; also to arrest silt, sand, and mud, and gradually raise the bottom above the level of high-water, in the manner of *groins*.

Military engineers make their gabions about 20 feet long, and 3 feet in girth on the mean, with bands at distances of from 1 foot to 1 foot 6 inches; in Holland the gabions are made from 24 to 27 feet long, from 1 foot 4 inches to 1 foot 8 inches in girth, and with bands at every 6 inches apart; and upon the Upper Rhine the gabions are made from 2 feet 6 inches to 3 feet 4 inches in girth.

Fig. 2138.



Gable.

The gabions of the Greeks, used in forming foundations or making inclined planes for raising architraves of buildings, were baskets of sedge filled with chalk and called *herones*.

Ga'ble. The triangular portion of the end of a building, bounded by the sides of the roof and a line joining the eaves.

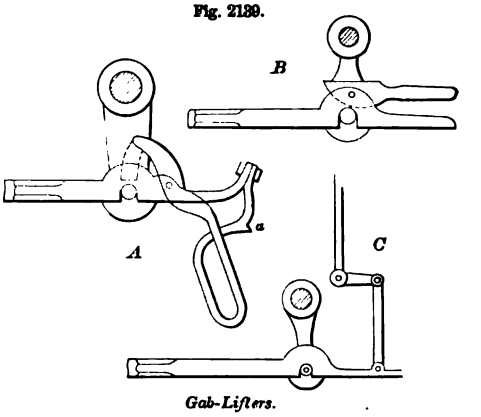
Gable-window; a window in the gable of a house.

Ga'blet. A small ornamental gable or canopy formed over a tabernacle or niche.

Gab-lift'er. A device for lifting the *gab-hook* from the wrist on the crank of the rock-shaft, in order to disconnect the eccentric from the valve-gear. In small engines, the eccentric-rod is simply lifted by means of the handle on the end.

In the apparatus *A*, by pulling up the spring han-

Fig. 2139.



Gab-Lifters.

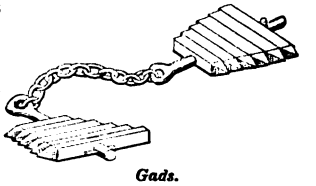
dle below until it catches in the notch *a*, the pin is disengaged from the *gab* on the eccentric-rod.

In *B*, the *gab* is lifted by the oscillation of an eccentric. When the handle of the latter is raised, the eccentric surface bears down on the pin and pries out the *gab-hook*.

In *C*, the operating rod proceeds from above and oscillates a rock-shaft, from which is suspended a link reaching to the eccentric-rod.

Gad. (*Mining.*) *a.* A steel wedge for opening crevices, natural or made by the pick.

Fig. 2140.



Gads.

The figure shows the mode of carrying them.

b. A small iron punch with a wooden handle, used to break up ores.

c. A *jumper;* a boring-bar.

Gaff. 1. (*Nautical.*) The spar which extends the upper edge of fore-and-aft sails, such as the *main*-sail of a cutter, smack, or other one-masted vessel; the *main* and *fore* sails of a schooner, the *spanker* of a ship, the *try*-sails or *spencer* of a brig or ship.

The lower end of the *gaff* has *jaws* which rest against and partially grip the mast. It is supported by the *throat-halyards* at the mast and the *peak-halyards* at the outer end.

The ropes which steady the *gaff* laterally are called *vangs*.

Gaff-sails are bent at the weather-leech to masts, or to *hoops* or *hanks* which run on the mast as the sail is raised or lowered.

Digitized by Google

2. The metallic spur fastened to the leg of a fighting-cock.

Cock-fighting was a common amusement in England in the twelfth century, and Fitz-Stephen says that it was customary for the schoolmaster to superintend the pit on the usual holiday cock-fighting on Shrove-Tuesday. The English, like the ancient Greeks, armed the heels with spurs. So, after all, our St. Domingo period was not so very long ago.

3. A fish-spear.

Gaff-hook. A heavy, barbed hook with a line, used in landing large fish.

Gaff-top'sail. A sail spread by a gaff above the main-sail of a cutter, or other fore-and-aft rigged vessel.

Gage. 1. An instrument for determining distances, sizes, proportions, as the carpenters' gages of various kinds; sheet-metal and wire gages, which are standards of measurement of thickness; test-gages or templets, by which work in detail is made to an exact set of standards, so that the pieces may be assembled; as the Springfield and other rifles, the Singer and other sewing-machines. There are about seventy-eight gages used for determining and verifying dimensions of the parts in the rifle musket, pattern of 1855; its lock, stock, barrel, ramrod, leaf-sight, bayonet, and mountings.

Whitworth's contrivance for testing the truth of a solid measure representing an English inch is a remarkable specimen of mechanical skill and accuracy. The block representing the inch is a rectangular prism of polished steel, originally cubical, but having its angles so truncated for convenience of manipulation that the terminal surfaces are one quarter inch square. At one of its extremities it abuts against a fixed stop, the other is opposed to the extremity of a screw of twenty threads to the inch, placed directly in the line of the axis. A single revolution of the screw advances the extremity, therefore, one twentieth of an inch. But the head of the screw is ten inches in circumference, and is divided into 200 parts. In turning this wheel, every division accordingly advances the screw one four-thousandth part of an inch. The divisions, however, are not traces, but teeth; and the screw-head is a gear-wheel, which is driven by a tangent screw lying horizontally in its plane and across its summit. And this tangent screw has also a head of 12½ inches in circumference, which is divided into 250 parts, each part being the twentieth of an inch. An entire revolution of the tangent screw advances the gear-wheel only one tooth, which, as we have seen, moves forward the end of the measuring screw one four-thousandth of an inch. A single division of the limb of the tangent screw-head will therefore produce a movement in the direction of measurement of only one two-hundred-and-fiftieth of one four-thousandth of an inch; that is to say, of one one-millionth part of an inch. Between the plane face of the standard inch and the extremity of the measuring screw opposed to it is a little steel plate with parallel and perfectly true surfaces. As the screw advances towards the plate a point is reached where the latter appears to be in contact, but when lifted it will be found to be free, as it will fall freely back, not being held by friction. If now the tangent screw be turned, a single division at a time lifting the plate after each movement, a point will be reached at which a single additional movement of advance will fasten the plate completely, so that the friction will prevent its fall.

Between these points the screw is advanced $\frac{1}{1000000}$ of an inch, and a retraction of the screw to this extent will free the plate so that it will fall; care being taken that disturbance of the equilibrium of temperature shall not change the conditions.

Whitworth's cylinder gages at the Paris Exposition were perforated steel plates, the perforations being highly polished within, and differing from each other in diameter by $\frac{1}{10000}$ of an inch. Corresponding to them were polished steel cylinders, one exactly fitted to each. As these cylinders lie side by side, it would be difficult for the eye to distinguish a difference of diameter between several of them; but when they are tried by the gages, each will pass freely through the aperture corresponding to its own number, but no one can be forced without an effort into one of a higher order. See MEASURING-MACHINE.

2. (*Physics.*) An instrument for determining the condition of a fluctuating object; as a tide, steam, rain, water, wind, current gage, etc. See METER.

3. *a.* The quantity of plaster of paris added to plastering mortar to facilitate setting.

b. Fine mortar with an addition of plaster of paris for a finishing coat.

4. The width of a railway track. See RAILWAY-GAGE.

5. The length of a shingle, slate, or tile which is exposed to the weather. Also called the *margin*. The hidden portion is called the *cover*.

a. Shingles are 18 inches long and expose 6 inches. That is the *gage*. There are thus three thicknesses on a roof.

b. Plain-tiles are 10½ inches long and have a gage of 6½ inches.

c. Pan-tiles are 14½ inches long; gage, 10 inches.

d. Slates vary in length and size. The gage is usually nearly half the length, so that the slates have a little over two thicknesses on the roof.

6. (*Printing.*) A strip of reglet with a notch in it to indicate the length of a page.

7. The depth of immersion of a vessel.

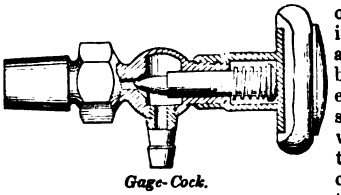
Gage-box for Shin'gles. A box of a certain size in which shingles are laid to form bunches of a certain number. A shingle is about 18 inches long, and every 4 inches of the edge counts as one shingle, so that if it were 12 × 18 inches it would count as 3. The box being 2 feet square, and the tails of the shingles lapping 6 inches, the butts of the layers are presented in alternate directions, each layer counting as six shingles. The box facilitates the counting and bunching.

Gage-cock. (*Steam-engine.*) One of two or more stop-cocks which are screwed into the boiler, one above the level at which water ought to stand in the boiler and the other below it. The ejection of steam and water respectively from the cocks indicates the water-level in the boiler to be between the two gage-cocks. Steam from both shows the water to be too low. Water from both shows the water to be too high.

Fig. 2141.



Gage-Cock.

In the gage-cock shown, the valve is operated in one direction by the tubular cap, and in the other by the steam pressure and a spring.

The *water-gage* is an exterior, vertical tube in connection with the boiler, and in which the water rises to an equal hight.

Gage-con-cus'sion. The rocking laterally of a railway carriage bringing the flanges of the wheels in contact with the edges of the rails.

Gaged-brick. Bricks for arch-building, molded or rubbed to a wedge shape to suit the radius of the soffit.

Gage-glass. (*Steam-engine.*) A strong, vertical, glass tube, connected at its ends by two cocks to the boiler, and forming an indicator of the depth of water in the boiler. It is illuminated at night by the *gage-lamp*.

Gage-lad'der. A square timber frame for raising the ends of wheeling planks in excavating. A *horsing-block*.

Gage-lamp. (*Railroad-engine.*) A lantern to throw light on the water-gage of a steam-boiler.

Gage-lathe. One designed to turn out chair-rounds, banister-columns, and all similar objects in which the cylindrical form is modified by contraction or enlargement of diameter, the formation of

Fig. 2142.

Gage-Lathe.

beads, etc., so as to present curves or broken lines in its contour.

The wood is placed between the centers, and is first brought to the form of a regular cylinder by means of a fixed chisel in a slide-rest. The slide-rest has two chisels, one of which reduces the wood to the form of a uniform cylinder, while the other cuts away the portions of the cylinder which must be removed in order to produce the varied outline which the design requires. This latter chisel is in a hinged holder, and a foot firmly connected with it rests on an iron rail or gage, which is cut to the contour which the wood is to have. As the slide-rest advances, this foot rises on the swells and sinks into the depressions of the gage; and the tool-holder, with its tool, rises and sinks with it, and thus transfers to the wood the precise contour of the gage. See NURLED WORK.

Gage Pa'per-cut'ter. A machine having a guillotine-knife descending with a draw-cut upon a pile of paper on a table. An adjustable fence regulates the *gage*, or size. See PAPER-CUTTING MACHINE.

Gage-pile. (*Pile-driving.*) A preliminary pile to mark the desired course.

Gage-rod. A graduated rod, used in measuring the capacity of barrels and casks.

Gage-saw. A saw having an adjustable frame or clamp, which determines the depth of kerf. Used by comb-makers and others.

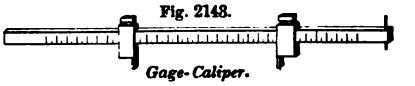
Gage-stuff. A stiff and compact plaster used in making cornices, moldings, etc. It consists of two thirds fine mortar, one third plaster of paris, with a little water.

Gage-wheel. One attached to the forward end of a plow-beam, to gage the depth of furrow.

Gag'ger. (*Founding.*) A T-headed piece of iron with a shank gradually enlarging towards the end, and placed in a mold so as to lock the sand together.

Gag'ing-cal'i-per. A tool in which are combined dividers, inside and outside calipers, and a

Fig. 2143.



Gage-Caliper.

graduated double scratch-gage. It is graduated to 16ths, 32ds, and 64ths of an inch.

Gag'ing-rod. An exciseman's or inspector's measuring-staff, for determining the interior dimensions of casks and other vessels holding liquids.

Gag-rein. (*Saddlery.*) A rein which passes over *runners* attached to the throat-latch, so as to draw the bit up into the corners of the horse's mouth when pulled upon.

Digitized by Google

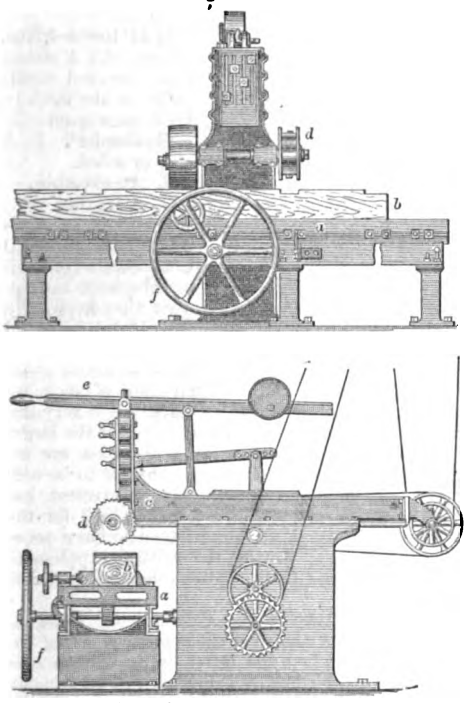
Gag-run'ner. (*Harness.*) A loop depending from the throat-latch; through it the gag-rein passes to the bit.

Gain. A mortise.

A beveled shoulder of a binding joist to strengthen the tenon.

Gain'ing-ma-chine'. A machine for cutting grooves across the face of a beam, usually to receive the shoulder of the tenon, so that the stud joist or post framed into the beam may have a strength to resist lateral strain greater than that due merely to the tenon which rests in the mortise proper. The machine is also adapted for rabbeting and transverse cutting generally. Two circular saws are placed at a distance apart equal to the width of the desired gain. A routing cutter may clear out the chip between the kerfs. The beam *b* is dogged on the bench *a*, and the saw-carriage *c* reciprocates above it, the

Fig. 2144.



Reciprocating Cross-Gaining Machine.

saws *d* being brought down to the work by the counterbalanced lever *e*. *f* is the wheel whereby the beam is moved longitudinally the distance between gains.

Gain'ing-twist. (*Rifling.*) A rifle-groove whose angle of twist becomes greater towards the muzzle. This allows the ball to be more easily started, gaining a greater velocity as it proceeds towards the muzzle. *Increase twist.*

Gai'ter. A covering for the ankle, fitting down upon the shoe. It is usually buttoned or buckled upon the outer side, and has a strap beneath the shank of the shoe.

It is sometimes called a gaiterette, as the term *gaiter* has been colloquially applied to the half-boot with a cloth top, and more recently to all bootees which closely embrace the ankle and the small of the leg immediately above it.

Ga'la. (*Fabric.*) A Scotch cotton fabric.

Gal'a-o-tom'e-ter. An instrument for ascertaining the quality of milk by its specific gravity. A *lactometer*. The former term is founded upon the Greek, and the latter partially from the Latin.

It consists of a stem and bulb, the latter charged with shot serving as ballast, so that it floats upright in the milk, the relative specific gravity being indicated by the centessimally graduated stem.

Gal'e-as. A low-built French galley worked with sails and oars. *Galeasse*, a Venetian galley. *Galiot*, a Dutch galley.

Ga-le'na. Native sulphuret of lead; from *galec*, to shine.

Gal'ets. The splinters of stone broken off by the stroke of the mason's chisel. Also called *spalls*.

Gal-i-le'an-tel'e-scope. The original form of reflecting telescope used by Galileo. It has a convex, converging object-glass, and a concave, diverging eye-glass. See TELESCOPE.

Gal'i-ot; Gal'li-ott. (*Nautical.*) Formerly, a galley propelled by sails and oars, having one mast and 16 to 20 seats for rowers; used by most of the maritime nations of continental Europe, and called by substantially the same name in the Latinic languages. Now a strong and cumbrous, bluff-bowed, two-masted vessel, used in the Dutch merchant service.

Gal'le-on. A large Spanish vessel with three decks, formerly used.

Gal'ler-y. 1. (*Fortification.*) A covered passage in a work, either for defence or communication. As one beneath the counterscarp and loopholed, or communicating between the enceinte and an outwork.

A gallery in a *scarp* having *embrasures* becomes a *casemate*.

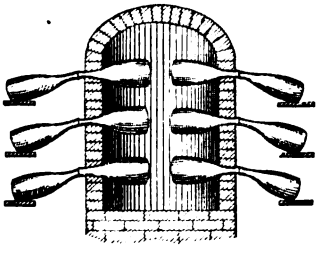
2. (*Nautical.*) A balcony projecting from the after part of a ship, as the *quarter-gallery, stern-gallery*.

3. A corridor; a partial story in a room for auditors or musicians.

4. (*Mining.*) An adit or drift in a mine, either as a means of working, of drainage, or of ventilation. The great drainage-gallery of the mines of Clausthal, in the Hartz, is 11,377 yards, equal to 6¼ miles long, and passes 300 yards below the church of Clausthal. Its excavation occupied from 1777 to 1800, and cost about $330,000. See ADIT.

Gal'ler-y-fur'nace. A furnace used in the distillation of green vitriol, consisting of a long gallery containing two or three tiers of retorts, 100 in each row. The gallery is a flue traversed by the flame of a fire. The neck of each retort projects through the walls of the gallery and enters an exterior receiver.

Fig. 2145



Gallery-Furnace.

Gal'ley. 1. (*Nautical.*) *a*. A low, flat-built vessel with one or more rows (*banks*) (see BANK, 5, *a*) of oars, said to have been invented by the Corinthians 700 B. C. The *biremes, triremes, quinqueremes*, etc., were galleys having so many banks of oars, — two, three, five, etc. The *pentecontori* had fifty oars in a single tier. The *galeasses* of the Venetians had 130 feet keel, 30 feet beam, three masts, thirty banks (see BANK, 5, *b*) of two oars each, each oar manned by six chained slaves. They were intro-

Digitized by Google

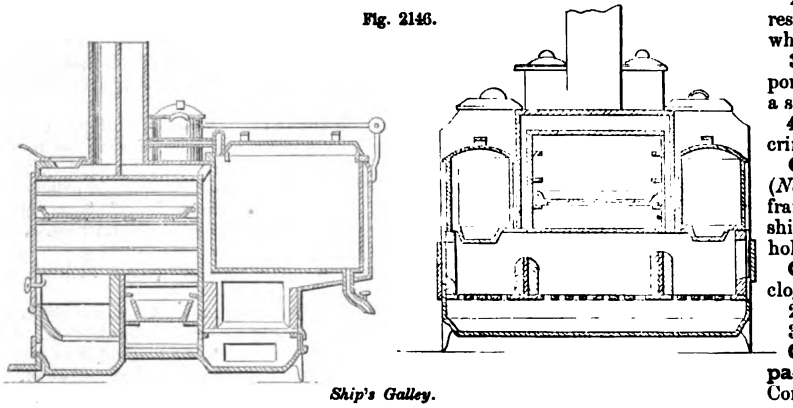
duced into France in the reign of Charles VI., and manned by criminals. He kept forty in his service. They were abolished by Louis XV. in 1748.

b. A clinker-built boat for ship's use, from 28 to 36 feet long, and with a beam equal to .2 of its length. It is a light, sharp boat, carrying from ten to twelve oars, and is used for speedy rowing on expeditions. It usually has six alternate oars rowed by a picked crew.

c. The cook-house on board ship which is on deck, or in a forward part of the vessel.

In the example, the caboose has three grates in front so arranged that one or all may be used at a time, and a rear grate, over which are three large boilers. Over a central front grate is a large oven, and between the front and rear fires is another; the products of combustion from the front fires circulate up around and over the front oven, on top of which are apertures for cooking-vessels; boilers may be placed over the side fires; and, on the top of the stove, boilers or cooking-vessels may be used. Pipes from the top of the large boilers convey the steam arising in cooking to the smoke-flue. Convenient arrangements are provided for the draft and for removal of ashes. The smoke-flue is so divided by a central partition as to give separate passages from the front and rear fires.

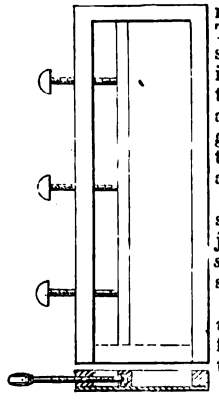
Fig. 2146.



Ship's Galley.

2. (*Printing.*) An oblong tray which receives matter from the composing-stick, and on which it is arranged in a column or page. The galley has a ledge on both sides and at top, half an inch in hight. From this it is taken to the imposing-stone and arranged in a chase. The galley sometimes has a groove to admit a false bottom, called a *galley-slice*.

Fig. 2147.



Printers' Galley.

In that illustrated the space for the matter is adjustable in width by a straight *side-stick* and thumb-screws, so as to *lock up* the *matter*.

Gal'ley-roll'er. (*Printing.*) A short inking-roller for taking *slip* proofs of matter in galley.

Gal'ley-slice. (*Printing.*) A sliding false bottom of a galley. See GALLEY.

Gal'ley-stick. (*Printing.*) A long tapering stick less than type high, which is placed beside a column of type in a galley, and the whole *locked up* or wedged in place by *quoins*.

Gal'li-vat. A large East Indian rowing-boat.

Gall of Glass. Scum of melted glass. *Sandiver.*

Gal-loon'. (*Fabric.*) A narrow cotton fabric used for binding shoes, etc.

A narrow binding stuff with threads of gold and silver. A silk, woolen, or mixed tape for edging, binding, or shoe-strings.

Gal'lows. 1. (*Husbandry.*) The central core of four corn-stalks interlaced diagonally, and bound at the intersection, forming a *stool* or support for cut corn, which is bound around it to form a *shock*.

2. (*Printing.*) The rest for the tympan when open.

3. The frame supporting the beam of a steam-engine.

4. A frame on which criminals are hanged.

Gal'lows-bitts. (*Nautical.*) A strong frame erected amidships on the deck to hold spare spars.

Ga-loche'. 1. A clog or sabot.

2. An overshoe.

3. A legging.

Gal-van'ic Ap'pa-ra'tus. (*Medical.*) Contrivances of various character and application, but agreeing in this, that they keep up a certain amount of galvanic action, which is intended to exert a remedial effect upon the parts of the body to which they are applied. While one cannot speak with confidence as to the actual value of such, we cannot condemn them, for we have but a very imperfect understanding of principles, and for the larger proportion of the curatives we possess we are indebted to empirics. This term ought not to be considered as one of reproach, for experiment has given us about all we have; rather look for the charlatans among those who pretend to have penetrated the arcana. Among the galvanic appliances may be cited bands, belts, chains, combs, rings, soles, spectacles, etc.

Gal-van'ic Bat'ter-y. Galvani, of Bologna, first observed the motion of the muscles of a frog under dissection, when the latter, lying upon a copper plate, were touched by a steel scalpel, exciting an electric current. He pursued the subject by specific experiments. Volta, of Como, repeated them, and originated the voltaic pile in 1800; also demonstrating that the influence was incident to the action of the metals, and did not abide in nerves; in fact that it was a current of electricity passing along the nerves and muscles. Duvernay in 1702 had observed and treated of the peculiar action of electricity, now known as galvanism.

Electricity, as developed by the galvanic pile, is great in quantity and weak in intensity. In this respect it is the inverse of the frictional electricity as excited by the electrical machine.

Galvanic electricity is also a steady current, while that of the electrical machine — as taken from the prime conductor — is intermittent and explosive.

From the proceedings of the National Institute of France, July 4, 1798: —

"Many of the members have been principally occupied with the care of ascertaining by a multiplicity

Digitized by Google

of experiments the phenomena of galvanism. This name is given to a discovery which Dr. Galvani, a member of the Institute of Bologna, made many years ago, and from which it results that when a contiguous series of metals, commonly different from one another, are put into contact on the one side of a nerve, and on the other with a muscle, or even with different and distinct parts of the same nerve, at the instant of the double contact a rapid and convulsive motion takes place in the muscle into which the nerve is distributed. This phenomena seems to present to the mind the idea of a circle, a portion of which is formed by the excitatory metals, and the other by the nervous and muscular organs. The rapidity of the effect, and the promptness of the communication, the nature and the participation of the exciting and interrupting substances, present very sensible analogies between the phenomena of galvanism and those of electricity. Some essential differences, however, appear to militate against this analogy, and will not suffer us to admit, at least for the present, the identity of a common principle."

A simple galvanic battery *a* consists of two bodies relatively electro positive and negative, immersed (or partially so) in a fluid which tends to act chemically upon one or both; the metals touching each other or having a conducting circuit connection.

Or: A current may be obtained from two liquids and one metal (or other substances); the respective sides of the metal being exposed to liquids of varying chemical energy upon the metal so presented.

Chemical action in all batteries develops electric energy or electro-motive force. This power is derived from the expenditure of metal, etc., and the actual value of the materials used is the principal item in determining the economic value of the process as a means of developing power. Its usual application as a motor has been in the form of the electro-magnetic engine, with coils and armatures. See ELECTRO-MAGNETIC ENGINE.

Two substances, which are conductors of electricity, being placed in contact and subject to chemical action by the presence of a fluid, will develop electric action; negative electricity passing from the body which is acted upon most powerfully, — the more easily oxidizable metal, — and positive electricity from the other substance. This is not stated as a principle, but a fact.

The metals, etc., are arranged in a series, each one of which is positive to all below it in the scale. The order is as follows: —

Zinc.	Iron.	Gold.
Lead.	Brass.	Platinum.
Tin.	Copper.	Graphite.
Antimony.	Silver.	Charcoal.

The more remote they stand from each other in the series, the more energetic will be the electric action developed by their contact under circumstances to excite chemical action.

In the formation of a simple galvanic circuit, the chemical action which excites electricity takes place through a decomposition of the liquid.

For instance, when a plate of zinc and one of copper are plunged in a weak solution of sulphuric acid, oxygen, and hydrogen, the elements of the water are separated from each other: the oxygen unites with the electro-positive zinc, forming sulphate of zinc, and develops negative electricity therein; while electro-negative copper is contrarily excited, and positive electricity is said to flow therefrom.

Some misconception may arise in the mind when it is said so frequently in a description that electric currents *flow;* but this mode of expression is perhaps as good as has been devised, and is certainly quite common. This curious agent or excitement is so imperfectly understood, that Professor Faraday remarked: "There was a time when I thought that I knew something about this matter; but the longer I live and the more carefully I study the subject, the more convinced I am of my total ignorance of electricity." The terms *flow, current,* etc., must, therefore, be considered merely as convenient conventional expressions.

This much seems to be admitted, that the positive and negative currents are coincident, and pass in opposite directions to restore equilibrium. In doing this they possess a certain energy which some ingenious men have made available as a positive force. In other cases the converse of the proposition is elucidated; as in electro-plating, where the energy derived from chemical action is made to excite electrical action; this again being transferred to a bath, where chemical decomposition is again effected and the equilibrium restored.

Volta discovered that by a repetition of the simple combinations, or, in other words, by a multiplication of the pairs of excited plates, the effect might be increased. His pile of plates arranged in pairs is but a multiplication of the single pair of plates, iron and copper, which caused the muscular action in the moist anatomical preparation of a frog with which they were casually brought in contact.

The cumulative effect of a number of simple batteries *b* (Fig. 2148) may be obtained by bringing them all into one circuit. Each copper plate is connected by a copper wire to the zinc of the next glass, and each transmits the electric current derived from the chemical action in its own glass, in addition to that derived from the action in the preceding glasses.

The trough-battery *c c'* was used by Sir Humphry Davy in his series of magnificent discoveries, 1806–8, when he isolated the metallic bases, calcium, sodium, potassium, etc. His trough had 2,000 double plates of copper and zinc, each having a surface of 32 square inches.

It is like the compound battery just cited, except that instead of separate glasses, a row of water-tight cells are made in a single trough *c'*, and the plates are united to a bar of wood *c* and connected by wires, the copper of each to the zinc of the next pair, and so on all through. This arrangement of the plates enables them to be withdrawn in a body from the dilute acid when desired.

The elements of the first galvanic batteries, copper and zinc plates immersed in a trough containing dilute acid, soon became sluggish and inert, and were capable of exerting their power for but a limited time without cleansing or renewal.

In 1836, Daniell's, the first permanent battery, was invented. This consists of a zinc and a copper element, each immersed in a separate saline solution, and separated by a diaphragm, originally of leather or animal membrane, but afterwards of porous earthenware. Smee subsequently substituted, for copper, silver upon which a coating of platinum was electrically deposited. Silver coated with platinum being cheaper and affording equally good results has been very generally employed, and latterly iron similarly coated has been used.

In the Austrian section of the Paris Exposition of 1867 there was exhibited a battery on the Smee principle, in which the positive element was fragments of amalgamated zinc, and the negative lead coated with platinum. This is said to be used in the Austrian telegraph-offices. Weak sulphuric acid is used as the bath in this battery.

Digitized by Google

A very permanent battery of low intensity has been devised by M. G. Farmer of Boston. It consists of an oval copper vessel forming the negative element, and which is nearly filled with a saturated solution of sulphate.

At one end is a porous cup within which is placed a smaller porous cup, which receives a cylinder of amalgamated zinc. The interior porous cup contains pure water, and the exterior cup a weak solution of sulphate of copper. The saturation of the liquid in the outer copper vessel is maintained by placing at the opposite end a third porous cup containing crystals of sulphate of copper, which are replenished as they are dissolved. If care be taken not to allow the water to fall too low, this battery will maintain its energy for many months.

Analogous to this is the battery of Fr. Secchi of Rome, which consists of a hollow cylinder of copper, having notches below to allow the liquid within and without to communicate freely, placed in the middle of a glass or earthenware cup, the bottom of which is covered with crystals of sulphate of copper. Over this is placed bibulous paper, fitting the annular space, over which is a stratum of sand on which rests a hollow cylinder of zinc surrounding the copper cylinder. This is filled with pulverized sulphate of copper. The space around the zinc is filled with sand. The whole is then moistened with water. According to the inventor, this battery acts for an entire year, water and sulphate of copper being added occasionally.

The gravity battery of M. Callaud of Nantes has a single cell, the separation of the liquids being effected by the difference in their specific gravities. The copper element is in the bottom, in the solution of sulphate of copper; and the zinc element is suspended in an upper part of the cell, in its own supernatant liquid. See CALLAUD BATTERY; GRAVITY BATTERY.

M. Leclanche employs in a carbon battery peroxide of manganese; subsequently he added carbon to the peroxide, the whole being ground into a paste.

Professor Bunsen, a few years since, introduced bichromate of potash instead of nitric acid in the battery bearing his name. This performs well for a time, but in consequence of the precipitation of sesquioxide of chromium upon the zinc it gradually loses power. Another modification dispenses with the porous cup, using the two liquids in mixture. The same objection attaches to this as to the former.

In the battery of Professor Thomsen of Copenhagen, a number of plates of platinum are immersed in dilute sulphuric acid, and are, by means of an electro-magnetic motor, successively brought into contact with the poles of a single cell of Daniell. The plates become covered by the decomposition of water with oxygen on one side and hydrogen on the other, giving rise to a powerful current in the platinum combination, which is maintained nearly constant when the contacts succeed one another rapidly and regularly.

To describe them more in detail: —

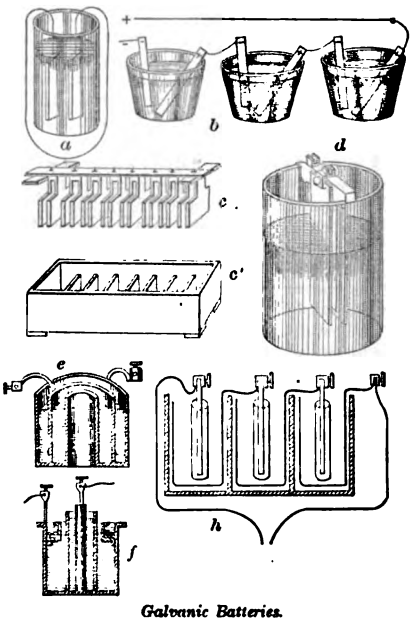
Smee's battery (*d*) has a plate of silver coated with platinum suspended between two plates of zinc, the surfaces of which have been amalgamated; that is, coated with mercury. The three plates are supported by a wooden bar, and depend within a jar partially filled with the usual acidulated solution, — dilute sulphuric acid. The wires and poles are connected with the zinc and platinum plates by small screw caps. The amalgamation of the zinc preserves the latter metal from active corrosion by the acid when the battery is not in use.

The sulphate-of-copper battery (*e*) has two concentric cylinders of copper joined to a bottom of the same metal. The middle cylinder is of zinc, and sets within the annular trough, which has a solution of sulphate of copper as an exciting liquid.

The screw caps are for attachment of the wires to the respective metals. A partition in the bath may be introduced, to allow the solution to pass, but restrain the passage of the solid products of the chemical decomposition. This would keep the metals free from a deposition which soon renders them inactive. The partition may be bladder or biscuit-porcelain.

Daniell's constant battery (*f*) is of the class of the sulphate-of-copper batteries. It differs from the preceding in having the sulphate of copper acidulated with one eighth of its bulk of sulphuric acid; in having a porous porcelain cylinder containing a solution of acid, 1 part; water, 7 parts; and in having a reserve of crystals of sulphate of copper on an

Fig. 2148.



Galvanic Batteries.

annular shelf in the bath. The reserve of acid and the salt of copper gives the battery a longer vitality and accounts for the name *constant;* and its continued effectiveness and evenness of action is due to the preservation of a clear metallic surface to the copper. The action is similar to the ordinary battery; the oxide of zinc formed is dissolved by the acid set free, but the hydrogen, instead of being set free at the copper plate, combines with the oxygen of the sulphate of copper, and the copper, thus set free from the acid, combines with the copper plate of the battery, and keeps a clear metallic surface thereon.

Grove's battery (*h*) is used for telegraphing and otherwhere when a powerful action is required. The glass jar has a cylinder of amalgamated zinc with an opening through one side to permit free circulation of the dilute sulphuric acid. Within this cylinder is a porous cup of biscuit-porcelain, containing strong nitric acid, in which is suspended a strip of platinum fastened to the end of a zinc arm projecting from the adjoining zinc cylinder.

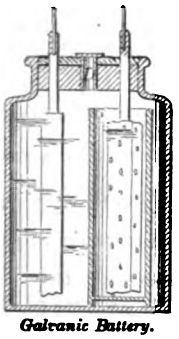
An objection to this battery consists in its emission of corrosive nitrous-acid fumes.

Digitized by Google

In Bunsen's battery, the platinum of Grove's battery is replaced by carbon. The Bunsen cell, properly so called, has a cylinder of carbon immersed in nitric acid, and the porous cell, containing zinc and sulphuric acid, is placed within it. In another form, introduced by Archerau, the zinc and sulphuric acid surround the carbon cylinder and nitric acid, which are contained in an interior porous cell; in consequence of the greater proportion of positive surface, this latter form evolves a greater amount of electricity than the former. Bunsen's battery is more powerful, though less compact, than Grove's.

In the Leclanche battery, the porous vase has a graphite plate to form the positive pole, and is filled up with a mixture of powdered graphite and peroxide of manganese. The inclosing jar has a plate of zinc and is filled with sand or sawdust moistened with a concentrated solution of sal-ammoniac. The cork has a central glass tube, and over this is a disk of rubber, whose edges are secured to the wax, its middle slit forming a gas-escape valve.

Fig 2149.



Galvanic Battery.

A newspaper item gives an account of the "smallest battery," as follows: "Mr. Collett writes from Heart's Content, 'I have just sent my compliments to Dr. Gould of Cambridge, who is in Valentia, with a battery composed of a gun-cap, with a strip of zinc, excited by a drop of water, the simple bulk of a tear.'" A telegraph that will do that must be nearly perfect.

The principal galvanic batteries are known as, —

Bunsen battery.	Gravity battery.
Callaud battery.	Grove battery.
Carbon battery.	Leclanche battery.
Daniell battery.	Single-fluid battery.
Double-fluid battery.	Smee battery.
Electropoion battery.	Thermo-electric battery.

See Deschanel's "Natural Philosophy," Part III. Appleton & Co.

Gal-van'ic Mox'a. A term applied by Fabré Palaprat to the application of platinum rendered incandescent by a galvanic current, as a cauterizing agent of the nature of a moxa.

Gal-van'ic Pile. A column of alternate plates, such as zinc and copper. See VOLTAIC PILE.

Gal'van-ized I'ron. The iron is cleaned by dilute acid and friction, is heated and plunged into a bath of melted zinc covered with sal-ammoniac, and is stirred about until the surface becomes alloyed with zinc. Small articles are treated in the same way, and, as they are found to be soldered together by the metal when dipped therefrom by the skimmer, they are placed in a crucible with charcoal powder, heated and shaken. Chains taken out of the zinc are shaken to separate the links. Wire is reeled through the zinc. Mallett recommends an amalgam of zinc, 2,292; mercury, 202; and about 1 of sodium or potassium; this melts at 680° F. The cleansed iron is dipped in this, and removed as soon as it reaches the temperature of the alloy.

Morewood and Rogers's method. The plates are tinned by placing them in a solution of muriate of tin in a bath, the plates alternating with granulated zinc, and thus forming a weak battery by which tin is deposited on the iron. The plates are then passed through a bath of melted zinc.

Gal-van'o-graph. (*Engraving.*) An Austrian process. A plate of silvered copper is covered by an artist with different coats of a somewhat transparent pigment, so that on the dark portions the paint is thick and raised, and the surface is relatively depressed in the light tints. A copy of this is made by the electrotype process, the darker being now the deeper portions, the whole forming an intaglio, like a copperplate, and is printed from by the copperplate-printing process.

Gal-van'o-glyph. A form of engraving. A ground is spread on a clean zinc plate and etched. Succeeding coats of varnish are spread by a roller on the ground, avoiding the obliteration of the lines, which become deeper with each coat. The finished plate becomes a matrix for a reverse impression obtained in the electro-bath, and this reverse is used to print from in the ordinary manner.

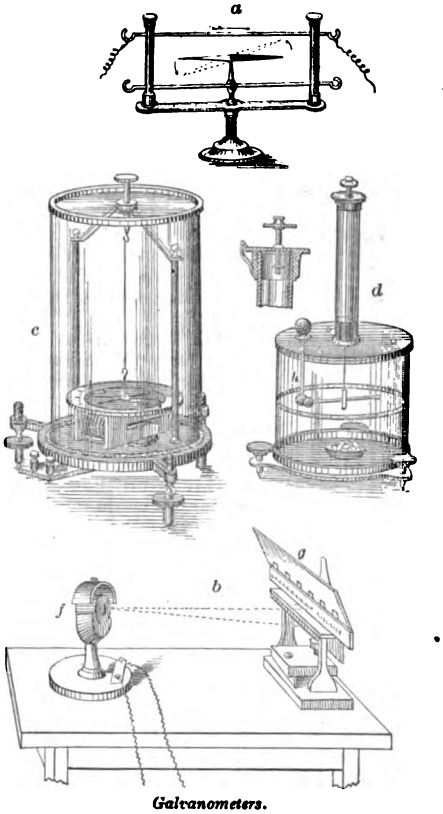
Gal'va-nom'e-ter. An instrument for measuring the strength of magnetic currents.

The instrument as usually constructed consists of a magnetized needle placed parallel to a wire, which, when electrically excited, causes the deflection of the needle. See ELECTROMETER; ELECTROSCOPE.

The discovery of this property in an electric current was by Œrsted of Denmark, in 1819. The principle was soon adopted by electricians in the construction of the indicator telegraph. Ampère, Arago, Schilling, Gauss, Weber, and Alexander all used the principle, but it received its perfected form by Cooke and Wheatstone, English patent, 1837. See INDICATOR-TELEGRAPH.

The tendency of the magnetic needle in the

Fig. 2150.



Galvanometers.

Digitized by Google

vicinity of an electrically excited needle held parallel to it is to assume a position at right angles to the wire conveying the current. By making the needle astatic, that is, by placing two needles with their poles in opposition to each other, they are not affected by the magnetism of the earth, and when thus arranged and surrounded by coils of wire the effect of the electric current is multiplied.

a (Fig. 2150) represents an apparatus for illustrating Œrsted's discovery. Two insulated wires are placed one above and one below a magnetized needle, and in a direction parallel to the magnetic meridian, and a current is passed through the wires; in the illustration, the current in the upper wire is represented as flowing from south to north, causing the north end of the needle to move to the west, and the south end to the east. A reversal of the current causes the needle to move in a reverse direction.

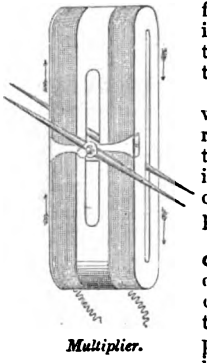
The astatic galvanometer *c* comprises an astatic needle suspended by a filament above a graduated plate, showing the degree of deflection. It is provided with set screws for attaching wires from an electro-magnet to the multiplying coil beneath the plate.

d is an instrument on the principle of the torsion balance of Coulomb, for observing the attraction or repulsion between the pole of a suspended bar magnet and that of a vertical magnet *h*. See INDICATOR-TELEGRAPH; TORSION-BALANCE.

Thomson's reflecting galvanometer, *b*, such as is employed in working the ocean cables, consists of a small mirror with a magnet laid across its back, both together weighing but 1½ grains. The reflector is suspended by a silk filament in the midst of a small circular coil of insulated copper wires *f*. A current transmitted through the cable and the coil induces a current which deflects the needle, and directs a little beam of reflected light from a lamp behind the horizontal scale *g* upon its graduated front; when the current is reversed, it sends the needle just so far in the other direction, and so by a combination of right and left motions and pauses the message is spelled out.

Gal'va-no-met'ric Mul'ti-pli-er. An instrument for increasing by repetition the intensity of the force of an electric current, as in the series of coils around the astatic needle of the needle-telegraph.

Fig. 2151.



Multiplier.

The convolutions of the wire carry the magnetic current a number of times around the needle, so as to increase its deflection, producing a considerable effect by a comparatively feeble current.

Gal'va-no-plas'tic Pro'cess. One in which the obtaining of casts by electro-deposition forms an adjunct in the process of multiplying printing surfaces, or obtaining copies of articles of "*bigotry* and *virtue*." See list under ENGRAVING; FINE-ARTS.

Gal-van'o-scope. An instrument for testing the presence of electrical forces.

It differs from a *galvanometer* in being merely qualitative, not quantitative, having no provision for determining the extent of the force.

Gam-ba'do. A leather legging for equestrians. It is wrapped around the leg, reaching from the knee to the foot, and is fastened at the side by clasps.

Gam'brel. 1. Originally, a bent stick like a horse's hind leg; used for suspending carcasses.

2. A roof with two pitches. A Mansard or curb roof.

Gam'brel-roof. (*Building.*) A roof with two sets of rafters at different inclinations. A *Mansard* roof. See CURB-ROOF.

Gam-broon'. (*Fabric.*) A kind of twilled linen cloth for linings.

Gam'mon-ing. (*Nautical.*) A lashing of ropes by which the bowsprit is bound to the cutwater to oppose the lifting action of the fore-stays.

Gam'mon-ing-hole. A hole cut through the knee of the head, for the gammoning.

Gang. 1. The rock enclosing a vein. *Gangue.*

2. A term applied to a set of tools so attached together or to a common stock as to act together; as a gang of bits, a gang-plow, a gang-saw, etc.

Gang-board. (*Nautical.*) *a.* A board with cleats, forming a bridge reaching from the gangway of a vessel to the wharf. A *gang-plank.*

b. A plank within or without the waist for a sentinel to pace.

Gang-cask. (*Nautical.*) *a.* A small cask for bringing off water in boats.

b. The cask in which drinking-water for immediate use is kept on deck.

Gang-cul'ti-va'tor. (*Husbandry.*) One in which a number of cultivator-shares are stocked in such a way as to be driven in a set; usually attached to a carriage portion on which the driver is mounted. See CULTIVATOR.

Gang-edg'er. A machine in which a movable and a stationary circular saw are mounted on one arbor for the purpose of dressing boards to uniform width, as they come from the log.

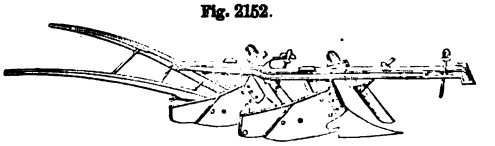
Gang-plow. Several plows stocked in one frame, generally supported on wheels and ridden by the operator.

Gangs of plows have been arranged for work by attaching a number of plows to a bar at proper distances, the motor being connected to the bar. The more usual form, however, consists of a number of plows attached to a frame which runs on wheels; the plows being the width of a furrow apart, and arranged in a receding order, so that the furrow slice, as it is raised, does not become jammed between the plows.

The wheeled frame, as used in the United States, is generally arranged with a tongue, so as to attach two or four horses, and when the plow is right-handed the off-wheel is the larger, as it runs in the furrow while the near wheel runs on the land.

The originator of the double plow seems to have

Fig. 2152.



Somerville's Double-Furrow Plow.

been Lord Somerville, who devoted much attention to the practical details of agriculture (1799).

His plow, which he called a *double-furrow plow*, consisted of a beam suitably bent for the attachment of two plows, one placed laterally and to the rear of the other, as usual. Mr. Ducket of Esper, England, used, in 1797, a double plow, drawn by four horses, and turning two furrows.

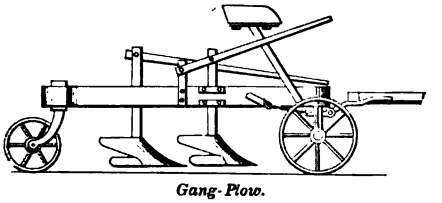
Digitized by Google

The plow was not commended in England, especially in those places where it took and yet takes two persons to manage one plow. The idea of making one man operate two plows was preposterous.

Lord Somerville invented a movable-flap mold-board, by which the hinged rear portion might be set out or in, according to the width required for stubble or sod plowing. A set screw at the back secured the flap at the desired adjustment. It is shown in the illustration of his gang-plow.

In the example (Fig. 2153), the plows are moved vertically by levers. The axle is bent to depress the

Fig. 2153.

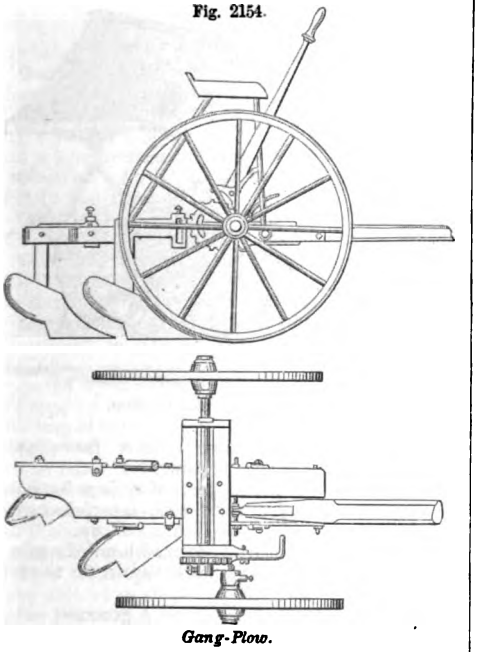


Gang-Plow.

furrow-wheel. The tongue is attached to one side of the center, to suit the position of the horses.

In Fig. 2154, the plows are raised or lowered by a lever and pawls attached to the axle, which has a toothed wheel, and has a crank near the hub for receiving the axle of the furrow-wheel, the tongue also being adjusted for the line of draught by a bolt through the clevis, and made fast to its rear end.

Fig. 2154.

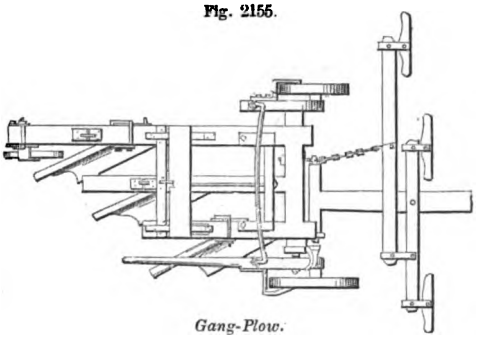


Gang-Plow.

The crank-shaped plow-standards, provided with a slot and set screw which passes through the boss and rests on the bed, are pivoted on bolts passing through a hole in the turn of the standard. The illustration shows a side elevation and a plan-view.

In the plow shown in Fig. 2155, the arrangement of the whiffletrees is designed to equalize the work of the horses. The levers, short axles, and sway bar are arranged to vibrate upon the ends of the axletree, for the purpose of raising and lowering the

Fig. 2155.

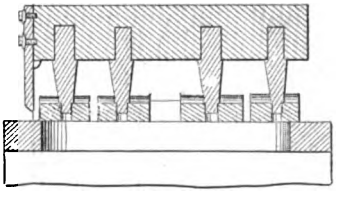


Gang-Plow.

plow-frame. When the machine is at work the sway-bar rests upon the folding frame, but when it is desirable to depress the plows the folding frame is drawn from beneath the sway-bar, which then assumes a lower position and rests upon the plow-frame.

Gang-punch. An arrangement of a number of punches in a single stock for punching fish-plates, or other things.

Fig. 2156.



Gang-Punch.

Gang-saw. An arrangement of saws placed parallel in a gate, so as to make a number of kerfs simultaneously, ripping up the log into lumber at one passage along the ways.

In the large saw-mills of the lumber regions, these saws are known as *slabbing-gangs*, *stock-gangs*, *Yankee-gangs*, *live-gangs*, differing in certain particulars and purposes. See those heads. The arrangement of several blades in one gate was introduced as early as the sixteenth century.

The illustration shows an English form of the gang-saw. *a a* is a cast-iron framework bolted to the foundation; *b*, the saw-mill floor; *c*, driving-shaft; *d d'*, fast and loose pulleys; *e*, fly-wheel; *h*, pitman; *g g*, saw-gate, which runs on slides *l l*. The log is represented as lying upon the bearer *b*, which is a part of the log-carriage, which runs upon rails on the timbers *m m*, the log being held down by the bearer above. The feed is by means of the eccentric *l'*, rod *h'*, and ratchet-wheel *p'*. The running-back motion is by means of the pulleys *l'* and spur-wheel *q'*. The other parts perhaps require no detailed description.

Gangue. 1. (*Smelting.*) The superfluous earthy matter of a smelting-furnace.

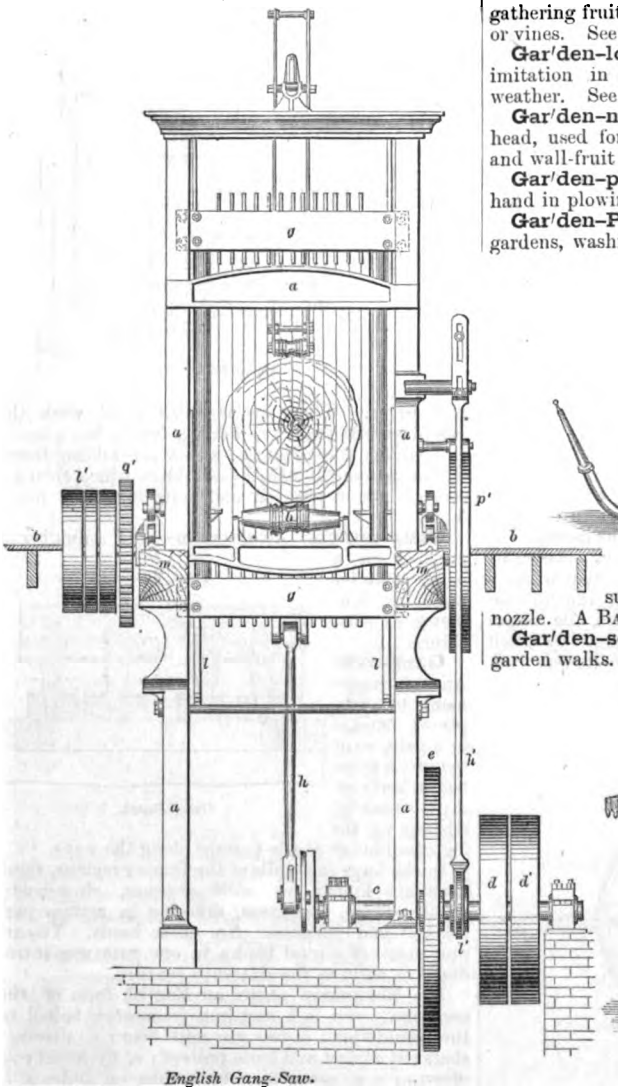
2. (*Mining.*) The mineral matters in which metallic ores are imbedded.

Gang'way. (*Nautical.*) The opening in the bulwarks of a vessel by which persons come on board or disembark.

Gan'is-ter. (*Metallurgy.*) A refractory material used for lining the Bessemer "convertors." It consists of crushed or ground silicious stone mixed with fire-clay. Its object is to save the iron convertor from destruction by the heat of the charge. Ground quartz, sand, and fire-clay.

Digitized by Google

Fig. 2157.



English Gang-Saw.

Atwood's compound for lining the bottoms of Bessemer converters consists of carbon, preferably that obtained from old crucibles, although anthracite or bituminous coal may be used, German, or other plastic clay, old ground fire-brick, Mount Savage stone-clay, and burned, or unburned sand.

These materials are ground together, and tamped into the mold.

Gap-win'dow. (*Architecture.*) A long and narrow window.

Gar'board-strake. (*Shipwrighting.*) The range of planks nearest to the keel. In the merchant service, the rabbet to receive the *garboard-strake* is made along the upper edge of the keel. In the navy, a groove is made half-way down the keel to receive the *garboard-strake.*

Gar'den-en'gine. A wheelbarrow tank and pump for watering gardens. See BARROW-PUMP.

Gar'den-er's-knife. A knife with a hooking blade suitable for pruning by a draw-cut.

Gar'den-er's-lad'der. A light ladder used in gathering fruit, pruning trees, or nailing up creepers or vines. See EXTENSION-LADDER; FRUIT-LADDER.

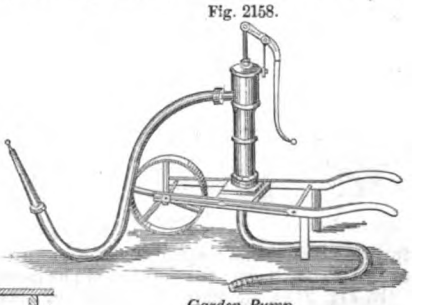
Gar'den-lounge. A seat of rustic work, or its imitation in iron, with an awning for summer weather. See GARDEN-SEAT.

Gar'den-nail. A cast nail with a pyramidal head, used for nailing up climbing plants, vines, and wall-fruit trees to brick walls.

Gar'den-plow. A small plow to be driven by hand in plowing between rows of garden plants.

Gar'den-Pump. A barrow-pump for watering gardens, washing carriages and windows. It has a

Fig. 2158.



Garden-Pump.

suction-hose and a discharging hose and nozzle. A BARROW-PUMP.

Gar'den-seat. A seat for croquet grounds or garden walks.

Fig. 2159.

Garden-Seat.

Gar'den-shears. Large shears for clipping hedges and trees and for pruning.

Gar'den-syr'inge. A form of syringe for watering plants, sprinkling them with insect-destroying solutions, and so on. See GARDEN-PUMP.

Gar'goyle. A quaintly formed head of a man or animal, employed as a decorative spout for the rain-water from a roof.

Gar'land. 1. (*Nautical.*) *a.* A grommet or ring of rope, made *selvage* fashion, and used to place around a mast or spar when taking aboard or stepping a mast.

b. A bag-net used by sailors to hold provisions.

2. An ornamental band used in Gothic work.

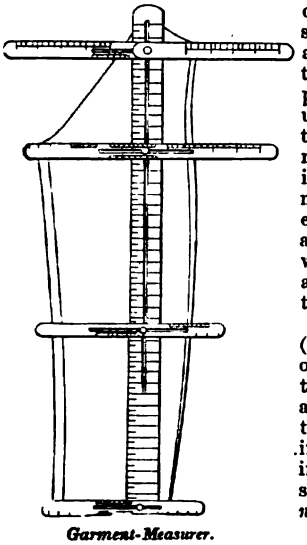
Gar'lic-sep'a-ra'tor. A machine for extracting the corms of garlic from wheat in those States which are infested with the plant. The device is usually an apron or roller of a somewhat viscid surface, to which the corm will adhere.

Digitized by Google

Gar'ment-cut'ter. A machine having a descending cutter of a given shape, which cuts from a pile of cloth beneath it a number of pieces of its own size. The die is shifted for the next piece, and so on for each piece which goes to make up the garment. Used in large clothing manufactories.

Gar'ment-meas'ur-er. A measuring scale for laying out garments. The vertical and lateral scales are graduated for obtaining the sizes and proportions of the figure, being adjusted to agree with the measures as taken in the usual manner. At the upper end are scales adapted to the width of the back and the hight of the shoulder.

Fig. 2160.



Garment-Measurer.

Gar'net. 1. (*Nautical.*) A sort of purchase. Fixed to the main-stay as a hoisting-in tackle, but useful in other positions indicated by names, such as *clew-garnet*, etc.

2. A hinge of T-shape, the cross-bar being attached to the hanging stile or post.

Gar'nish-bolt. (*Building.*) A bolt having a chamfered or faceted head.

Ga-rook'uh. A vessel of the Persian Gulf, having a length of from 50 to 100 feet, a short keel, and a long overhanging prow and stern.

Gar'ret. An upper apartment of a house, immediately under the roof.

Gar'ret-ing. Small splinters of stone inserted in the joints of coarse masonry.

Gar'rot. (*Surgical.*) A tourniquet formed of a band and a stick, the former being twisted by the revolution of the latter.

Gar-rote'. A Spanish instrument of execution. The victim is fastened by an iron collar to an upright post, usually in a sitting posture, and a knob operated by a screw or lever dislocates the spinal column, or a small blade severs the spinal cord at the base of the brain.

Gar'ter. A semicircular plate, acting as a key, which passes through a slot in the wooden jaw of a bench-vise, and enters an annular groove in the cylindrical neck of the bench-screw, so that when the latter is unscrewed it brings *out* the jaw.

Garth. A fish-weir.

Gas. Exudations of gas from the earth have been noticed in ancient and modern times, and in many countries.

In China, these exudations, either natural or resulting from deep boring, have been utilized from time immemorial for lighting towns in the neighborhood of these jets. In boring for salt water, imprisoned reservoirs of carbureted hydrogen have been reached, and the gas thus obtained has been utilized in China, and in the valley of the Kanawha, West Virginia, in evaporating the brine.

Gas flowing naturally is or has been used in the neighborhood of Fredonia, New York; Portland, on Lake Erie; Wigan, Great Britain (in 1667); and in many other places.

The uses made of it by the Magi, or fire-worshippers of Persia, have not been properly examined or determined; but the holy fires of Baku, on the shore of the Caspian, have attained some celebrity, and are maintained by a natural stream of carbureted hydrogen.

Paracelsus remarked the disengagement of gas when iron was dissolved in sulphuric acid. Van Helmont, a Belgian chemist, gave it the name of "gas," and distinguished gases from atmospheric air, and also, on account of their non-condensibility, from vapors. Van Helmont died in 1644.

Oxygen was first discovered by Dr. Priestley in 1774; he obtained it by heating red oxide of mercury, and called it *dephlogisticated air*.

Scheele and Lavoisier a year or two later made the same discovery, independently of the English inventor, as Humboldt thinks. It was termed *empyreal air* by Scheele; *vital air* by Cordorcet. The name *oxygen* was given to it by Lavoisier.

Black and Cavendish, in 1766, showed that carbonic acid (*fixed air*) and hydrogen gas (*combustible air*) are specifically distinct aëriform fluids.

Gas was distilled from wood in Paris in 1802; from oil by Dr. Henry, in 1805; from refuse, oily, and fatty matter by Taylor, and patented in 1815.

The operations of the Chinese being unknown to the "outside barbarians," the streams of inflammable gas were for many centuries only objects of wonder and conjecture in the various countries of Europe where they issued from the soil. Occasionally, small bladders of gas had been collected and burned, but no suspicion seems to have entered the minds of the observers that there was anything valuable involved.

The artificial production of gas from coal dates in the seventeenth century, and the early examples of its manufacture and use are as follows: —

Dr. Clayton, rector of Crofton, England, distilled illuminating gas from coal, and detailed the experiment to his friend Dr. Boyle, in 1688. Dr. Boyle announced it to the Royal Society before his death, which happened in 1691. Dr. Clayton obtained what he called an "uncondensable spirit," which, as it issued in a jet, was caught in a bladder and used for experiments; the gas being repeatedly lighted and blown out.

About fifty years afterwards the account was published in the "Philosophical Transactions," and appears to have drawn attention to the subject, as from this point we find a chain of experimenters and then a line of practical developers.

If the series is to be briefly stated, we shall give it thus: Dr. Clayton, Bishop Watson, Murdoch, Winsor, Clegg; a clergyman, a bishop, an engineer, an enthusiast, a mechanic.

In 1726, Dr. Hales, in his work on "Vegetable Statics," states that 158 grains of coal yield 180 cubic inches of gas.

In 1750, Watson, Bishop of Llandaff, distilled coal, passed the gas through water, and conveyed it in pipes from one place to another.

In 1786, Lord Dundonald erected ovens or retorts in which he distilled coal and tar, and burned the issuing gas. He seems to have considered it an amusing experiment, and no more.

In 1792, Mr. Murdoch, of Redruth, Cornwall, England, erected a gas-distilling apparatus and lighted his house and offices by gas distributed through service-pipes.

In 1798, Murdoch lighted with gas the works of Boulton and Watt, Soho, near Birmingham. On the occasion of a public rejoicing for peace, 1802,

Digitized by Google

he made an illumination of the Works; probably an outside exhibition of his pet, on the walls of the establishment. Trafalgar, Austerlitz, and Jena, within four years afterwards, is a curious commentary.

In 1801, Le Bon, of Paris, lighted his house and garden, and proposed to light the city of Paris.

The English periodicals of 1803 and thereabout refer to the proposition of Murdoch to use the gas obtained by the distillation of coal, and state that the use of the gas for light, heat, ammonia, or oil would be an infringement of the patent of the Earl of Dundonald; farther, that the amount of water produced by the combination of the hydrogen of the gas and the oxygen of the air would suffuse the curtains of a room with moisture, and would render it necessary "to wring out the curtains and other linen furniture of the apartments on the morning subsequent to the illumination by the burning of the coal smoke." — *Monthly Magazine*, London, June 1, 1805.

In 1803 – 4, Winsor lighted the Lyceum Theater and took out a patent for lighting streets by gas. He established the first gas-company.

In 1804 – 5, Murdoch lighted the cotton-factory of Philips and Lee, Manchester, the light being estimated as equal to 3,000 candles. This was the largest undertaking up to that date.

In 1807, Winsor lighted one side of Pall Mall, London; the first street lighting.

Westminster Bridge was lighted in 1813.

Houses of Parliament, London, in the same year.

Streets of London generally, 1815. Streets of Paris, the same year.

James McMurtrie proposed to light streets of Philadelphia, 1815.

Baltimore commenced the use of gas, 1816.

Boston, 1822.

New York City, 1825.

The Newton gas-well, six miles from Titusville, Pa., discharges at the rate of three millions of cubic feet of gas every day of twenty-four hours. The gas issues under a pressure of from twenty to thirty pounds per square inch, and for the most part goes to waste. Pipes have been laid to Titusville, and two hundred and fifty dwelling-houses, shops, etc., are now supplied with the gas for illumination and fuel. For heating purposes it is admirable, but for illumination it requires to be passed through naphtha, as it is deficient in carbon.

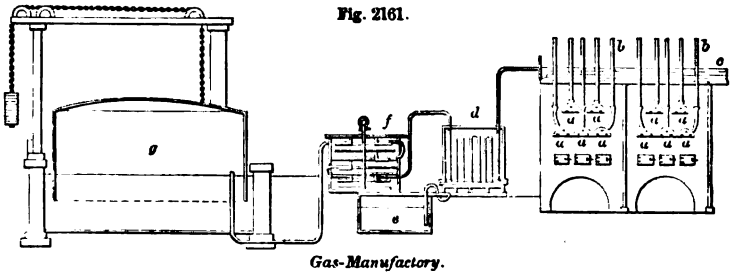
If the owners could satisfy themselves of the continuity of the gas flow, we presume that pipes would be laid from the well to several of the large cities, such as Pittsburg, Cleveland, and Buffalo.

The process of making gas consists in the distillation of coal, though other forms of hydrocarbon will yield it, and the subsequent purification of the same to purge it of noxious matters, — tar, ammonia, and sulphur. These operations are conducted respectively in the GAS-RETORT, CONDENSER, WASHER, and PURIFIER (which see).

The coal is placed in the retort *a* by means of long scoops, which are handled by three men, two scoopfuls forming a charge, — 220 pounds. The retort is of iron or clay; the latter is now preferred. The retort has its open end exposed at the furnace-wall, so as to receive the charge, and is surrounded by the flames and heat of the furnace. Each retort is connected by its branch pipe *b* with the main *c*, which conducts the gas evolved to the condenser *d*. The operation of charging the retort is quickly and skillfully performed, so as to limit the escape of gas. When the charge is introduced, the cap is replaced and luted to make the joint gas-tight. The fire expels the gas from the coal in the course of five hours, and the coke is then ready to be withdrawn. This is done by long rakes, and it is wetted to prevent its burning. The coke weighs less than the coal by the amount of gas evolved, but is nearly double the bulk.

The gas flows in company with other vapors from the retort, and these impurities are removed by successive operations. It is first conducted through the convoluted pipes of the *condenser d*, by which the gas is cooled and the tar precipitated. From thence it passes to the *washer e*, in which it is brought into intimate contact with water to remove the ammonia, which has so great an affinity for water that it leaves the gas. From thence the gas is conducted to the *purifier f*, where it is passed between layers of damp, powdered lime, arranged in a tier of shelves on a box. The lime absorbs the sulphur and permits the gas to pass off in a purified state, fit for consumption. See also GAS-PURIFIER.

Fig. 2161.



Gas-Manufactory.

The holder *g*, in which the gas is stored, consists of inverted sheet-iron cylinders, which are supported by chains and counterweights from pillars of iron. The cylinder is open at its lower end, and the edge dips into a tank of water, so that the cylinder rises as the gas is driven into it and sinks as it is withdrawn by consumption. The inlet and outlet of the gas is by pipes whose terminations are above the surface of the water. From the holder the gas proceeds to the mains and service-pipes. See GAS-HOLDER.

To govern the flow of the gas, a regulator or governor is applied (see GAS-REGULATOR), whose duty it is to limit the flow, according to the elevation of the locality to which the gas is supplied, and also to maintain an equable pressure to avoid flickering and inequalities in the light. One form of regulator is a bell-shaped chamber suspended from a beam whose other end has a balance-weight, being in construction similar to a gas-holder. Gas is admitted to the interior of the "bell" by a pipe whose end is above the surface of the water in the tank into which the bell is inverted, and a similar pipe conveys the gas away. Over the upturned mouth of the inlet-pipe is suspended a cone which partially closes the aperture when the pressure of gas is greatest, and uncloses the opening when the pressure diminishes, so that the size of the orifice is in the inverse ratio of the pressure, and the consequent speed of the passing fluid. Valves working on the principle of the bellows, and actuated by the ascending and descending bell, are effective for this purpose.

In the distribution, valves are used to cut off the

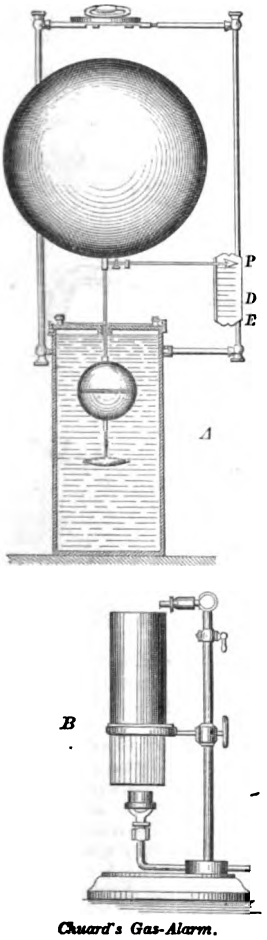
Digitized by Google

supply from certain localities for repair or other purposes. These are hydraulic water-traps, in fact, consisting of inverted cups shutting down over the top of the pipe, which is turned up for that purpose beneath a small dome; or other mechanical devices are used, such as spring or slide valves, which are essentially similar to some described under VALVES. An essential part of the distributing apparatus is the meter; these are *wet* or *dry*, and are described under GAS-METER.

Gas-a-larm'. A device invented by M. Chuard, and described in the forty-fourth volume of the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, 1845.

It is called by him a "gasoscope" (*A*), and was intended to indicate the presence of carbureted hydrogen in mines and dwellings. It is constructed like a very delicate areometor, with a light metallic stem, surmounted by a thin glass globe filled with atmospheric air. The lower ball, which gives it buoyancy, and the suspended weight, which maintains its vertical position, are submerged in a vessel of distilled water. The weight is graduated, so that the normal condition of the air causes the finger to indicate zero on the scale; *P*, pure. When the surrounding air becomes mixed with hydrogen, the relative weight of the glass globe will be changed, its contained air being heavier than the air and gas by which it is surrounded. It will then sink, and the pointer will indicate upon the graduated scale a dangerous degree of suffusion of the air; *D*, danger. When nearing the point *E*, explosion, a stud on the stem trips a trigger or comes in contact with a magnet, by which a lever is moved and a hammer caused to sound upon an alarm-bell.

Fig 2162.



Chuard's Gas-Alarm.

Several other devices founded upon endosmotic action have been proposed. A bladder of air is placed in a position exposed to the action of escaping hydrogen, and by the absorption of gas its form or specific weight becomes changed, the change being made the means of mechanically actuating a device which sounds the alarm.

Another gas-alarm for mines or rooms consists of a galvanic battery with a bell and a glass tube filled with chloride of palladium. This metallic salt is extremely sensitive to the presence of carbonic-oxide gas. A small quantity of the gas will at once throw down some of the metal from the solution, and this precipitate collecting in the bottom of the tube, at once establishes a connection in the current of electricity, and the violent ringing of a bell will warn the sleeper of his danger.

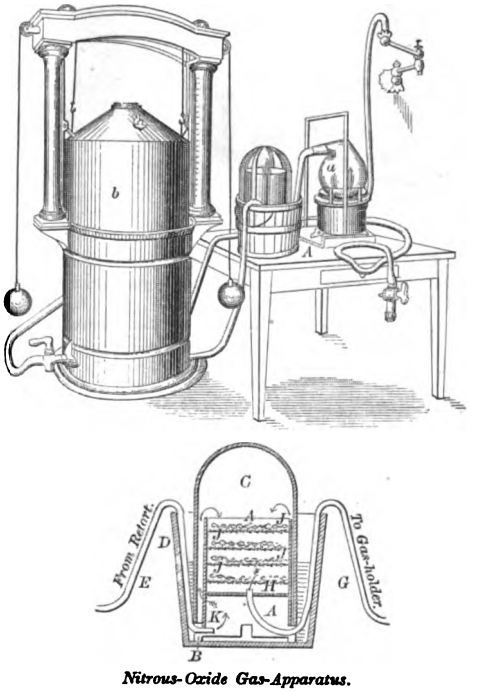
Van der Weyde's burglar-alarm *B* is so arranged that the opening of a door or window to which it is connected will turn a gas-cock and emit gas into a cylinder, where it is exploded by contact with a small, constant burner above.

It has an upper metallic cylinder and a lower apron of wire gauze, into which the gas enters as the lower gas-cock is turned by the opening of the door. As the gas reaches the upper end of the tube and is ignited at the burner, it produces a shrill sound which may be heard by the inmates of the house. The apparatus may be placed within the room which is being surreptitiously entered, or at any other point, connected by wire with the door of said room, and conveniently situated to alarm the person in charge.

Gas'a-lier. A stem or dependent tube having a group of branches tipped with gas-burners.

Gas-ap'pa-ra'tus. The apparatus for making nitrous-oxide gas is shown in Fig. 2163. It consists

Fig. 2163.



Nitrous-Oxide Gas-Apparatus.

of a retort *a*, purifier *A*, and gas-holder *b*. The purifier *A* is a copper cylinder, divided into two chambers by a gas-tight horizontal disk *H*. The cylinder is pierced just below the disk by a number of small holes. *B* is a wooden stand; *C*, a glass vase covering the cylinder; *K*, a short pipe, to which the conducting tube is attached, curving under the vase, and passing into the lower chamber and connecting with the retort by a rubber tube *E*. A similar pipe communicates with the upper chamber, and is connected with the gas-holder by tube *G*. The cylinder is loosely fitted with four wire-cloth disks *J*, placed equidistant, on which is spread lime.

Digitized by Google

The whole apparatus sits in a vessel *D*, which should be about half full of water.

The gas passes from the retort by tube *E* into the lower chamber, is partly washed by the water, passes out at the small holes into the inside of the vase, up into the top of the cylinder, down through the lime into the pipe *A*, and to the gas-holder by tube *G*, as indicated by the arrows.

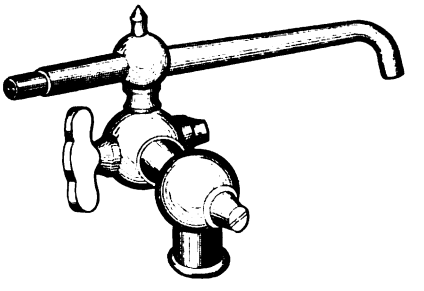
Gas-bellows. A kindling device consisting of a hollow poker attached by a flexible tube with the gas-pipe. The end of the poker is perforated, and is thrust among the coals in the grate or furnace, so that the ignited jet may start the fire.

English patents of 1854 and 1856 describe bellows connected with a gas-reservoir, and also a portable apparatus containing compressed gas, and having a nozzle which may be thrust among the coals.

Gas Blow-pipe. A form of blow-pipe designed to be attached to a gas-pipe, for using gas instead of

Fig. 2165.



Gas Blow-Pipe.

oil or alcohol. The atmospheric air is driven through the center tube, adding force and giving a cylindrical form to the flame, which issues at an annular opening.

Gas-brack'et. A branch proceeding from a wall and having on its end a burner or burners.

Gas-burn'er. The jet-piece at which the gas issues.

It consists of a slit or of a number of orifices disposed so as to produce the shape of flame required.

The *fish-tail* flame is made by two oblique orifices at an angle of about 60°, so as to cause the jets to cross each other; the object is divergence, to spread the gas and bring the carbureted hydrogen in contact with the air.

The *cock-spur* burner *a* has three apertures, one central and the others divergent.

The *union* burner *b* has a row of holes so disposed that the jets touch and nearly coalesce, each maintaining in part its distinctiveness.

The *bat's wing c* has a slit aperture instead of holes, giving a flat, fan-like flame.

The *beak* has a round, smooth hole $\frac{1}{75}$ of an inch in diameter.

The Boccius light, named after the inventor, consists of two concentric, metallic cylinders, placed on the flame and within the usual lamp-glass, so as to modify the combustion and increase the brilliancy of the light.

The *Argand* burner *d* is a hollow annulus, the

Digitized by Google

upper surface of which is pierced with a circle of small openings having a diameter of from $\frac{1}{32}$ to $\frac{1}{50}$ of an inch. It also has a central aperture to allow access of air to the inside of the flame as well as the outside.

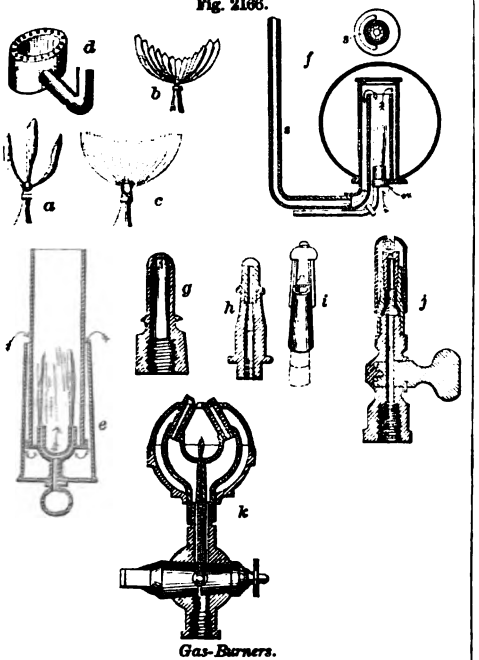
The jets from each hole unite to form a cylindrical flame. The holes are about $\frac{1}{8}$ of an inch asunder, and when there are ten holes in the circle the middle opening will be $\frac{1}{10}$ of an inch in diameter. With twenty-five holes the central orifice will be about 1 inch in diameter.

Burners with ten, fifteen, twenty, or twenty-five holes have central apertures $\frac{3}{32}$, $\frac{1}{4}$, $\frac{3}{8}$, and $\frac{10}{100}$ of an inch in diameter. The flames of these burners may be raised without smoking to the height of $3\frac{1}{2}$, 3, $2\frac{1}{4}$, and 2 inches respectively. The glass chimneys for the burners mentioned should be $\frac{6}{10}$, $\frac{7}{10}$, $\frac{8}{10}$, $\frac{9}{10}$ of an inch in diameter respectively.

The *Bude* burner has two or three concentric Argand rings.

The *Winfield-Argand* has a metallic button above the annulus to deflect the central current laterally.

Fig. 2166.



Gas-Burners.

A contraction of the chimney above the jet has a similar effect upon the exterior envelope of air.

Leslie's Argand has a series of small tubes arranged in a circle, which eject the gas in a conical form just below the contraction of the chimney.

Frankland's burner *e* is an Argand with two chimneys, the outer one standing on a plate so as to be closed at bottom, and the air passing between the two for the supply of the flame.

Faraday's ventilating burner *f* removes the products of combustion, and prevents their mingling with the air of the apartment. It is shown in vertical and horizontal section, the arrows indicating the course of the air, and *s* being the exit-pipe for the effete air and gases.

g is a three-slit burner.

k is a soapstone-tipped burner.

In *i*, the elongated ring upon the burner has on its sides two arms supporting fine platinum wires bent over at the top, between which is a spongy platinum with wires at the bottom to ignite the gas issuing from the jet of the burner.

j is also a platinum coil-lighter, the resistance of the metal causing it to become red-hot when a current of galvanic electricity is passed through it.

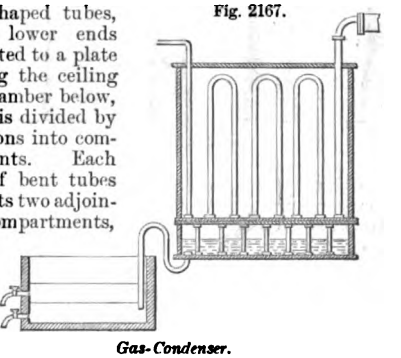
In *k*, a small axial tube supplies the jet in the bulbous cap around the main burners; the jet remains lighted while the main pipe is closed, and is closed when the main pipe is lighted. The same spigot acts to make these changes of connection, having side ramifications which conduct to the axial tube in the former case, and a divisional piece which closes the said tube in the latter case.

Gas-check. A ring or plate at the rear of the charge chamber in some kinds of breech-loading ordnance, such as Broadwell's, Krupp's, Armstrong's, etc. It is designed to close the rear aperture completely, and prevent escape of gas rearward. See GAS-RING.

Gas-con-dens'er. The gas from the retorts is passed through the condenser to rid it of the tar. It comes hot from the retort, and is passed through the convoluted pipes, which are surrounded by water, precipitating the tar. It is the second in the series of apparatus in gas-making, — *retort, condenser, washer, purifier.* From the latter it passes to the gas-holder and the distributing mains. The condenser gathers about eight or ten gallons of tar from the gas produced from 2,000 pounds of coal. The tar is used, in connection with paper and gravel, for roofing; and combined with sawdust, gravel, and various other matters, in making pavement. It is distilled to obtain different grades of hydrocarbon liquids used for illumination and in the arts.

The form of the condenser is a tank having a submerged series of siphon-shaped tubes, whose lower ends are bolted to a plate forming the ceiling of a chamber below, which is divided by partitions into compartments. Each rank of bent tubes connects two adjoining compartments,

Fig. 2167.



Gas-Condenser.

so that the gas is compelled to pass through each set, by which it is brought to the temperature of the air, the tar and ammoniacal liquor being condensed and collected in the lower chamber, whence they are drawn off into a cistern.

Where 100,000 cubic feet of gas are produced every twenty-four hours, the condenser should have a surface of from 800 to 900 square feet.

Gas-en'gine. An engine in which the motion of the piston is caused by the combustion or sudden production or expansion of gas in a closed cylinder.

The first gas-engines were gunpowder-engines, the gas generated by the explosion being the means of expelling the air, the condensation of the gases producing a partial vacuum in the chamber. See Brown's English patent, vacuum engine, 1824.

D'Hautefeuille, in 1678, seems to have been the

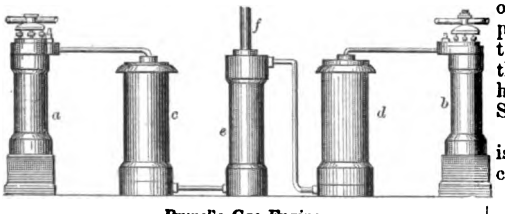
Digitized by Google

first to use this power; Hugyhens applied it in a cylinder so that the atmospheric pressure might force a piston downward when the vacuum was thus formed beneath it. Papin substituted a bell-valve over the air-eduction port, for the collapsible leathern tubes of Huyghens.

In 1791 Barber took an English patent for a gas-engine in which a stream of carbureted hydrogen gas was introduced at one induction port and a quantity of atmospheric air at another, the resulting combustion giving an explosive force against the piston. Street, in 1794, proposed to use the expansive power of heated gas instead of its explosive power. Lebon's French patent of 1799 described the distillation of carbureted hydrogen from coal, and its introduction into the cylinder beneath the piston and simultaneously at another channel a proper proportion of atmospheric air. The mixed gases were then exploded by the electric spark (see also Pinkus's English patent, 1840), their dilatation furnishing the desired motive-power. The engine was self-regulating and operated two pumps, one of them designed to introduce the supply of gas, and the other that of air.

Brunel's gas-engine (1825) consisted of five distinct cylindrical vessels; the two exterior vessels *a* and *b* contain the carbonic acid, reduced to the liquid form, and are called the *receivers;* from these it passes into two other vessels *c* and *d*, called *expansion vessels.* These latter have communication with the central vessel or working cylinder *e*, the piston of which is operated by the alternate expansion and

Fig. 2168.



Brunel's Gas-Engine.

contraction of the gas, giving motion to machinery through the medium of the piston-rod *f*.

Heat and cold are alternately applied to the contents of the receivers by means of steam, water, etc., circulating through pipes which pass through the *receivers.* The air in the *expansion*-chambers presses upon a body of oil in the chamber, and through it transmits the pressure to the piston. It being much easier to make an oil-tight than a gas-tight joint, the direct access of gas to the piston is thus obviated.

If water at 120° be passed through one cylinder, the gaseous contents will have an expansive pressure of 90 atmospheres, and cold water be passed through the other receiver, the latter will exert a force of from 40 to 50 atmospheres. The difference in the pressures, say 45 atmospheres to the square inch, will be the power on the piston (at the start).

Davy and Faraday, about 1823, succeeded in reducing several gases to a liquid state by means of great pressure and very low temperature. Upon releasing the pressure, the gases were found to again expand to their original volume. This discovery again turned attention to gas-engines. It was ascertained — a result which was of course expected — that in the condensation a considerable amount of caloric was rendered sensible, and that in re-expanding the same amount of caloric was rendered latent.

Cooper, 1835 (English patent, No. 6875), describes an engine in which one part oxygen and two parts hydrogen are ignited to produce a vacuum alternately on each side of a piston.

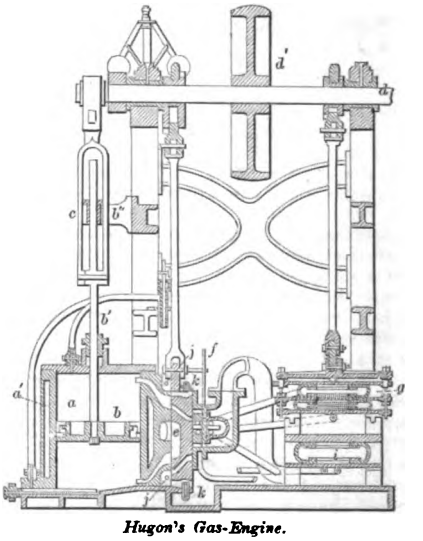
In Sir James C. Anderson's (English patent, No. 11,273), two cylinders open at the ends are placed end to end. A web of gun-cotton is fed to cylinders alternately and ignited by electric spark.

Johnson's British patent of 1841 proposed to introduce pure hydrogen gas and oxygen instead of atmospheric air, in order that the water, the resultant of the explosion, might render the vacuum practically perfect.

Otto and Langen's gas-engine is an upright hollow column, having a heavy piston, whose rod is a rack acting upon a cog-wheel on the fly-wheel shaft; as the piston ascends, the cog-wheel slips loosely on the shaft. The mixed gases, coal-gas and air, are exploded by communication with the gas-jet, which is kept constantly burning. As the gases rapidly condense after the explosion, the atmospheric pressure, aided by the weight of the piston, is made effective upon the shaft of the wheel by the engagement of the rack-teeth with those of the spur-wheel. See Dr. Barnard's "Report of the French Exposition," pp. 60 – 63. The same excellent report gives an account and illustration of the Lenoir gas-engine, of which three hundred were, in 1862, in use in France. The essential portions are a horizontal cylinder with a piston which communicates motion by a crank to a shaft which carries a heavy fly-wheel. The great weight of this wheel is for a double purpose: to absorb the force suddenly developed by the explosion, and so moderate the speed at this period; and, secondly, to carry the machine over the one half of its period in which the driving-power is absent. Like the Otto and Langen engine, a water-jacket around the cylinder prevented the latter from becoming overheated. The explosion was made by electric spark. See AIR-ENGINE.

In Hugon's gas-engine, a small quantity of water is introduced into the cylinder along with every charge of gas. By its evaporation the water absorbs

Fig. 2169.



Hugon's Gas-Engine.

some heat, and in becoming steam it prevents the abrupt fall of pressure which follows the explosion

Digitized by Google

when the gases are used entirely dry. The mode of firing is by permanent lights placed on the outside of the cylinder, jets being inflamed at these and taken to the charges at the respective ends of the cylinder. As the explosion exhausts the oxygen of the cylinder, the jet is extinguished. The gases are admitted by a slide-valve, and the lighted jet by a supplementary slide.

The cylinder is shown at *a*, the small space *a'* being the interval between it and the jacket, which is filled with cold water.

b is the piston with its rod *b'*, guided by the support *b''*.

c is the connecting-rod, which is forked below, and attached above to the crank.

d is the arbor moved by the crank, and carrying the pulley *d'*, by which the motive-power is applied. The same arbor carries the fly-wheel at the extremity.

e is the slide carrying the portable gas jets *k k*, and serving also to open the escape passage to the exhaust gases.

f is the induction slide, admitting the explosive mixture to the cylinder.

g is the compressor by which the inflammable gas is introduced into the chamber where the mixture is formed.

i is the reservoir of inflammable gas.

j j are the fixed jets, and *k k* the movable.

In Hugon's English patent 653 of 1863, the explosive force of the gas acts upon a column of water which transfers the force to the piston.

See also Lenoir's patent, March 19, 1861; Dick's, 1867; Million, 1867.

The ammoniacal engine has been termed a gas-engine, but this latter name is more fairly applicable to those engines in which the force is obtained by the inflammation of the charge, rather than to those in which the motor is an elastic vapor under pressure.

Frot's ammonia-engine resembles the steam-engine so closely that comparative experiments with the vapor of water and of ammonia have been made with it. See AMMONIACAL ENGINE.

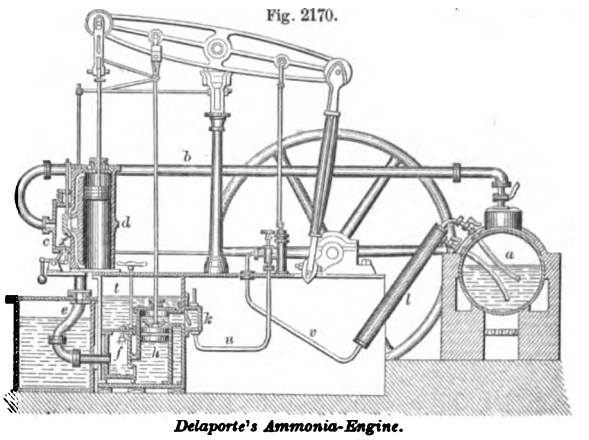
R. Waller (English patent, No. 1019 of 1854) uses condensible and permanent gases; as carbonic acid, ether, air. Vaporizes by steam or hot water.

Arbos (English patent, 3108 of 1862), steam and gas combined.

N. H. Barbour (No. 46,769, March 14, 1865) has a traveling car with reservoir supplied with carbonic acid from condensing stations along the route. See COMPRESSED AIR-ENGINES on this principle; Bompas and others, pp. 602–604.

In Delaporte's ammoniacal gas-engine, *a* is the boiler, *d* the cylinder, and *b* the tube communicating between the cylinder and the boiler. *c* is the valve-box, and *x* the slider by means of which the gas is introduced alternately above and below the piston. *e* is the eduction-pipe and *f* the condenser and dissolver. In this machine, the condenser and dissolver are not separate, as in Mr. Frot's. The water of injection is introduced by a pipe and rose-jet at the top of the condenser *f*. The solution passes from *f* into *h*, from which it is withdrawn by the piston *h*, passing through the reservoir *k* and the tubes *u* and *v*, by which it is returned to the boiler. As its return is opposed by the elasticity of the gas in the boiler, it must be forced in, and a small forcing-pump is employed for this purpose. The tube *v* is surrounded by a jacket *l*. The water which has been deprived by heat of its ammonia is withdrawn from the bottom of the boiler by the lower tube, and passes into the jacket *l*, where it imparts a portion of its heat to the solution in the

Fig. 2170.



Delaporte's Ammonia-Engine.

tube *v*, which is on its way to the boiler. It is then discharged by a connection, not shown, and carried through a refrigerator, which is also not shown, after which it is conveyed into the vessel *t*, and is employed for injection into the dissolver *f*. See also AIR-ENGINE.

Gas-fit'ter's Gage. An arrangement by which the tightness of the joints in a line of pipe is ascertained. The pipes being filled with air by a pump, the pressure-gage in connection therewith remains stationary if the joints are perfect. If the gage fall, ether may be admitted to the interior and the escape detected by a torch.

Gas-fit'ter's Tongs. One for pinching gas-pipe, holding them while screwing joints together, or screwing gas-burners into their sockets.

In Fig. 2172, a cutter for cutting off the ends of pipes, a

Fig. 2172.

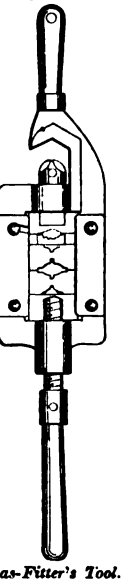


Fig. 2171

Gas-Fitter's Tongs.

Gas-Fitter's Tool.

scraper for clearing its surface before forming the screw, dies for cutting the thread, and a cramp for holding the pipe to turn it, are arranged in a frame or stock fitted for the purpose.

Digitized by Google

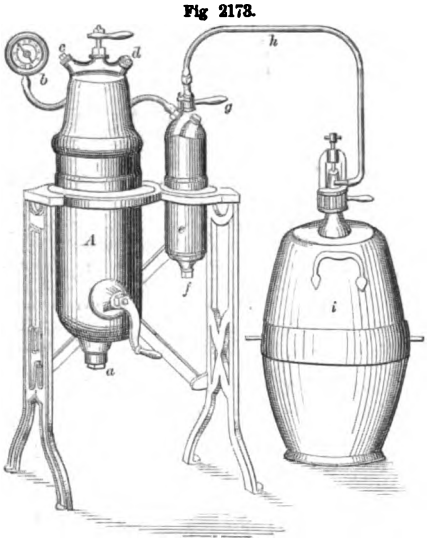
Gas-fur'nace. 1. A small furnace, much employed for laboratory purposes, and which is so arranged as to receive the maximum heating powers of the gas without regard to its illuminating purposes. Various forms have been contrived.

2. A furnace of which the fuel is gas from burners suitably disposed in the chamber for the purpose required. Steam-boilers and metallurgic furnaces are sometimes thus heated. See Siemen's English patent, 1861.

Gas-gage. An instrument for ascertaining the pressure of gas. A bent graduated tube containing water or mercury, open at one end and with the other screwed into the vessel containing the gas. It resembles Lind's anemometer (p. 99), except that the open end is exposed to the gas pressure instead of wind pressure.

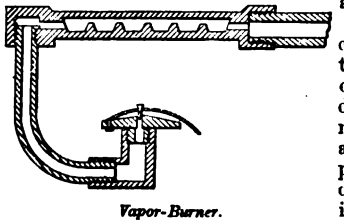
Gas-gen'er-a'tor. A chamber in which gas is evolved. The term includes: — 1. The retort in which volatile hydrocarbons are evolved by heat, as in the ordinary gas-apparatus. 2. The machine in which air is saturated with the vapor of liquid hydrocarbon. (See CARBURETOR.) 3. The machines in which carbonic-acid gas is evolved for aërating water or other purposes. Such is that shown in Fig. 2173, in which *A* is the vessel containing the sulphuric acid in an upper chamber, and the other materials in a lower portion. *a* is a discharge for spent matter, *b* is a pressure-gage, *c d* are openings for charging, *e* is the purifier, *f* the discharge for the exhausted materials of purification, *g* a stop-cock in the pipe *h* leading to the vessel *i*, which contains the water to be aërated.

Fig 2173.



Carbonic-Acid Gas-Generator.

Fig. 2174.

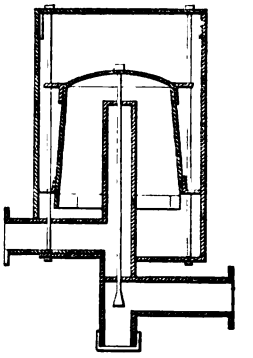


Vapor-Burner.

Of an allied character is that for producing the deutoxide of nitrogen for anæsthetic purposes. 4. A device belonging to a vapor-burner in which the liquid hydrocarbon passes from its reservoir into the chamber *b* between the plates *a a*, where it is vaporized by heat from the burner *f*. The vapor of the oil passes by the pipe *d* to the burner, and the flame is regulated by the thermostatic spring and plug *h i*.

Gas-gov'ern-or. The gas-governor is a small gas-holder into which the gas enters, and from which it is passed to the mains with a regulated pressure. The velocity of gas in the mains increases in the ratio of the square root of the pressure, so that by adding to this it may either be driven more rapidly or to a greater distance.

Fig. 2175.



Gas-Governor.

Gas-heat'er. An apparatus contrived for the application of gas to specific purposes of heating.

While every jet of inflamed gas will warm the surrounding air, it becomes necessary, in adapting it specifically for warming purposes, to change the jet from its usual position and in some other respects. In deference to the custom, the gas-heater is sometimes made to assume the forms of grate-bars or logs of wood in the usual fire-place.

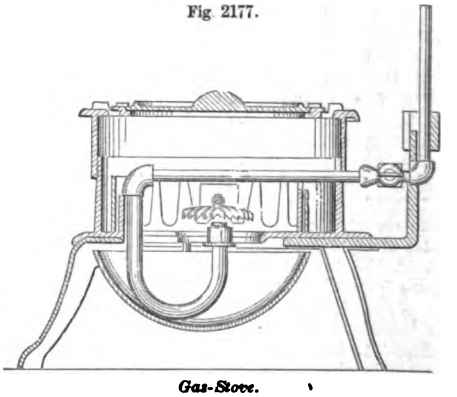
Fig. 2176.

Goddard's Gas-Heater.

Goddard's gas-heater has perforated bars in the form of a basket-grate, and over these is spread a quantity of asbestus, which makes an incandescent mass, resembling a coal fire.

In Fig. 2177, the air-regulating dish is formed in the segment of a sphere, and has its concave side upward. The influx of air is regulated by the vertical distance between the edge of the dish and the bottom of the stove. Above the frame is a rotating disk, consisting of a series of inclined sectoral wings, which distribute the heat.

Fig. 2177.



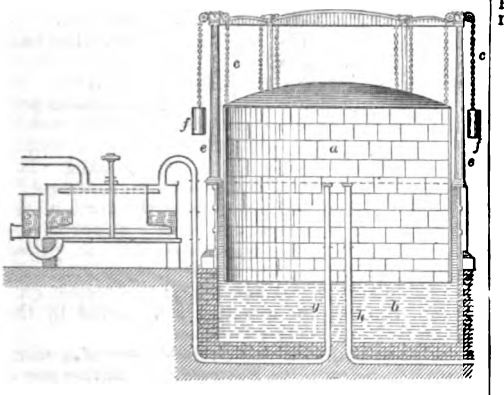
Gas-Stove.

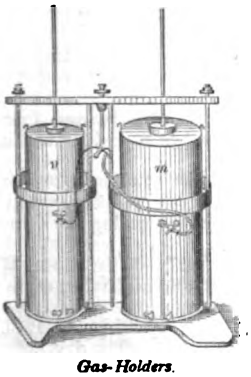
Gas-hold'er. A large, vertical, open-bottomed cylinder *a*, inverted into a tank *b* of water, and used

Digitized by Google

for storing the gas from the retorts after purification. Its hight is usually equal to its radius, in accordance with the geometrical law that a cylinder having those proportions has the greatest capacity with a given surface.

Fig. 2178.





Gas-Holders.

Gas-holders are now made much larger than they were some years back. A work on this subject, written a few years since, speaks in admiration of the Westminster gas-holders as having a capacity of 250,000 feet. We have far exceeded this.

Gas-holders are made of sheet-iron plates riveted together and daubed with tar inside and out to prevent leakage. They are stayed with rods and braces internally, and are suspended by chains *c* which pass over pulleys on the posts *e* which encircle the holder. Weights *f* on the pulleys partially counterbalance the weight of the holder, the extra weight of the latter being the power which drives the gas through the mains and service-pipes to the burners of the district supplied by it.

Within the frame the holder ascends and descends as it is filled or emptied of gas, the lower edge remaining submerged in the tank to prevent the escape of gas. The gas is introduced and withdrawn through pipes *g h*, whose terminations are above the level of the water in the tank of the gas-holder.

Valves regulate the inlet and outlet apertures, so as to direct the gas into the holder, or to allow it to pass therefrom, as may be required. To prevent the freezing of the water in the tank, the surface of the water is covered with tar in the space between the outside of the holder and the side of the tank.

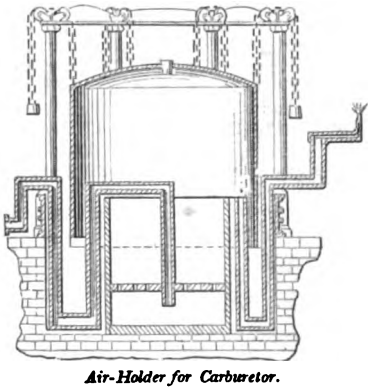
Gas-holders are made of various sizes, from 100,000 to 1,000,000 cubic feet capacity.

For laboratory and exhibitional use a pair of gas-holders is found useful, containing respectively oxygen and hydrogen gas. Their purpose in this connection for the exhibition of the oxy-hydrogen light, or the microscope illuminated by that means, requires that the hydrogen-holder *m* shall have double the capacity of the other one *n*, as the combining proportions of the two gases to form water is oxygen, 1, hydrogen, 2, by bulk. By weight the statement is very different: oxygen, 8, hydrogen, 1; oxygen being sixteen times heavier than hydrogen.

Gas-holders are sometimes made of flexible impervious bags, or sheet-metal cases. These require no particular description.

The weighted gas-holder is the air-forcing device

Fig. 2179.

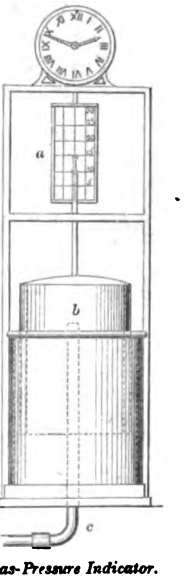


Air-Holder for Carburetor.

in some forms of carburetors, as in M'Avoy's. In the illustration, the tank *B a* contains the liquid hydrocarbon; the air comes in by pipe *c* to the lower part *a*, where it is distributed through the liquid by perforated plate *b*, and ascends into the holder *A*. It passes off by pipe *d* to the burner.

Gas-in'di-ca'tor. This instrument is connected to the main pipe, and indicates by the rising and falling of a spring piston, or a weighted gas-holder *b*, the pressure of gas in the pipe *c*.

Fig. 2180.



Gas-Pressure Indicator.

A register is attached, having a pencil which rises and falls as the pressure varies; and as the pencil rests on a sheet of paper on a drum *a* traveling at a given rate, the diagram gives a faithful report as to pressure and time by the combined movements of the paper and pencil. A *gas-register*.

Gas'ket. 1. (*Steam-engine.*) A strip of leather, tow, or textile fabric, to form a packing or calk a joint.

2. (*Nautical.*) A plaited cord by which the sails, when furled, are bound close to the yards or gaffs.

Gas-light'ing Ap'pa-ra'tus. Devices for gas-lighting are matches, spongy platinum, fuse-pipe, electrophorus or voltaic circuit, eliciting a spark, or heated platinum coil. See, in this connection, LIGHTING-DEVICES and GAS-BURNER.

Spongy platinum is heated to redness when exposed to a jet of hydrogen gas, and has frequently been used for this purpose. The effect is more immediate and certain when a stream of pure hydrogen is emitted temporarily, as in Fig. 2181, in which a small cylinder containing spongy platinum is attached to a gas-burner, which throws a stream of

Digitized by Google

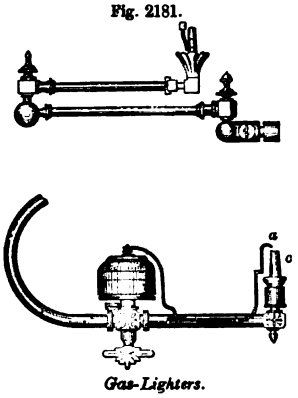
gas thereon to ignite the same. A mixture of pure and carbureted hydrogen is first passed through the pipe, and after ignition the flow of the former is stopped.

The *fuse-pipe* is a pipe leading from an accessible position to burners at a distance, and having a row of small openings throughout its length. Gas being turned on issues at these jets, and, a light being applied, runs along the pipe from jet to jet till it reaches the distant burners. It is then turned off.

Gas-lighting by electricity is adopted as a measure of convenience in reaching distant burners, or those in situations difficult to reach. Of the former character may be cited the circles of burners in the dome and rotunda and the cluster in the tholus of the Capitol at Washington; and of the latter the works at the royal arsenal, Woolwich, England, where all the burners are fixed upon the outside of the windows.

The means adopted are an electric spark produced by friction, as in the *electrophorus*, or a resistance body, such as a platinum coil placed in a voltaic circuit.

Fig. 2181.

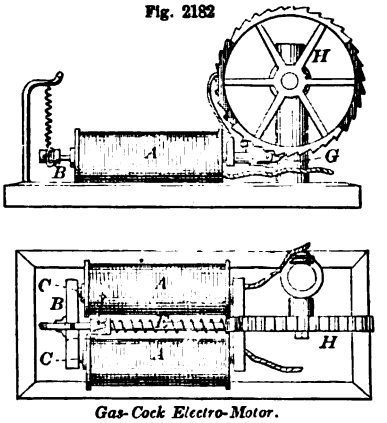


Gas-Lighters.

The electrophorus has assumed many forms: a glass piston in a metallic baton lined with Canton flannel; a pair of disks with cloth-lined faces, etc. (See ELECTROPHORUS.) Fig. 2181 shows one form in which the device is attached to the stop-cock, so that the act of turning the same to let on gas shall generate a spark at the break of the circuit between the point *a* and the tip of the burner *c*.

The other mode of gas-lighting by electricity is by means of a voltaic circuit. A battery is placed in any convenient place, and is connected by insulated copper wires with the burners. A coil of fine platinum wire, forming a part of the circuit, is placed above and a little on one side of the opening

Fig. 2182



Gas-Cock Electro-Motor.

in each burner, and this coil becomes heated by its resistance to the passing current, and so ignites the gas, which has been previously turned on. Or, a break may be made in the circuit immediately above the gas orifice, and the spark leaping across the interval lights the gas. These modes have been adopted in a number of legislative halls, public buildings, manufactories, and stores, on both sides of the Atlantic, and the electric current has been also the means of turning on the gas at the distant points by means of a ratchet-wheel on the axis of the gas-cock, which is turned by the successive pulsations of the armature, the latter being alternately actuated by electric connection and a retracting spring. This device is shown in Fig. 2182. The sliding rod *E* is a stem attached to the armature *B*, and has a click *G* which acts upon the teeth of the ratchet-wheel *H*, whose axis is the spigot of the gas-cock. When the voltaic current is passed through the coils *A*, the armature *B* is attracted, and the ratchet moved one tooth; the voltaic connection ceasing, the armature is retracted by the spring ready for another impulse.

On a less extended scale, the burners of a room may be connected with one pole of a battery and a wire hidden in a tassel with the other pole; when the wire is brought near to the burner, a spark leaps across the interval and lights the gas.

Clock-work has also been employed to turn on and light gas at a set time; and also to turn off the gas at a prearranged time.

Gas-main. A principal gas-pipe leading from the works, and having branches and distributing pipes.

See also *hydraulic main*, invented by Clegg in 1807, and forming a part of the gas-producing works.

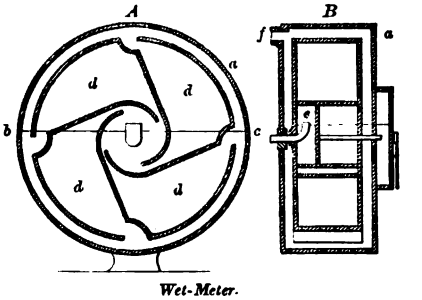
Gas-me'ter. A device for measuring the quantity of volume of passing gas.

Citizen Seguin, of the National Institute of France, described a gas-meter at the sitting of the Institute, October 6, 1797.

The wet-meter was invented by Clegg in 1807, and improved by Crosley in 1815. The dry-meter was invented by Malam in 1820, and improved by Defries in 1838. Many improvements and variations have been added since by various parties.

A (Fig. 2183) is a longitudinal and *B* a transverse section of the wet-meter, which is composed of an

Fig. 2183.



Wet-Meter.

outer box *a* partially filled with liquid, as water, alcohol, or glycerine, to the level of the line *b c*, somewhat above its center. Within this is journaled an axis carrying a series of buckets *d d d d*, each capable of containing a definite quantity of gas, which is admitted through the pipe *e* at the central part of the meter, and causes the buckets successively to rise, maintaining a continuous rotation. The gas passes out through a pipe *f* at the upper part of the meter, its quantity being measured by a series of multiplying gear-wheels; these derive their

Digitized by Google

motion from the axis on which the buckets are journaled, and register 100s, 1,000s, 10,000s, and 100,000s of feet, the amount being indicated on a series of dials.

Valves are arranged to cut off the supply of gas when the water in the meter rises above or falls below certain limits.

The constant-level meter has an automatic arrangement of float, which, as the water wastes by evaporation, descends and immerses an equal portion of its bulk, which is always equal to the quantity of water which has disappeared.

The principle of the dry-meter may be understood by describing it as a machine having a bellows of known capacity, and alternately filled with gas and emptied, the pulsations being counted by a register. Or it may be described as a cylinder with a reciprocating piston, whose motions are counted, the gas being discharged from the alternate ends of the cylinder as the piston reciprocates. The pressure of gas is the motor, and the changes of direction of motion are effected by induction and eduction valves, much as in a steam-engine.

Sugg's (English) photometric gas-meter is designed for experimental use, to show not only the volume of gas which has been consumed at the end of a given time, but also the rate per hour or per minute that the consumption is proceeding. It has two index-hands, one revolving once in a minute, and moved by clock-work; the other making a complete revolution during the passage through the meter of one twelfth foot of gas. The standard of the London companies is that the gas, when burned at the rate of 5 cubic feet per hour, shall give a light equal to the burning of 14 sperm candles, each consuming 120 grains in the same time.

Gas'o-line. A light grade of petroleum.

Gas-om'e-ter. The term is applied in England to a large vertical cylinder, closed above, and with its lower edge immersed in a water-tank, and used for holding gas. Such a vessel is more appropriately called a GAS-HOLDER (which see). The term *gasometer* probably arose from the fact that the *holder* is of known capacity, and as it rises affords so ready a means of estimating the quantity contained, thus constituting a *meter*. It is usual now to provide a *meter* in gas-works, whose duty it is to measure the gas on its way to the holder.

From gasometer has arisen the term *airometer*, when a vessel of similar construction contains atmospheric air. This is used in one form of blower, in ventilating-machines, in aspirators, machines for carbureting air, and for other purposes. See AIR-HOLDER.

Gas-oph'a-ner. An indicator of the presence of poisonous gases. It is described as a lump of boracic acid, heated to redness in chlorine, and blown into a bulb. Carbonic acid, sulphureted hydrogen, and other deleterious gases, give peculiar reactions on the bulb, and indicate their presence.

Gas'o-scope. An instrument for detecting the presence of carbureted hydrogen in the atmosphere.

It is used, or should be, in coal-mines, to give an alarm when a dangerous and explosive condition of the air supervenes. It may also be applied to detect a leak in the gas-apparatus of a building, or to give an alarm when Aminadab from the rural districts blows out the gas on retiring to bed at the hotel or at the house of his city cousin. See GAS-ALARM.

Gas-pipe. Gas-mains are laid in sections, the small end of one entering the wide socket of the adjacent section. A packing of hemp dipped in tar is driven in to form a joint; over this is a luting of clay, within which is poured hot lead.

Service-pipes are of various metals, wrought-iron tubing being now more common than any other. The sections of distributing-pipe have screw-socket couplings.

The mains are laid with a gradual slope, and at the foot of each incline, or where two descending slopes meet, a reservoir is formed to collect water of condensation. This chamber has an iron cover into which is fixed a pipe, which descends nearly to the bottom of the reservoir. At the summit of the pipe is a screw, which admits the attachment of a pump, by which the liquid in the reservoir is removed.

Gas-pipe Tongs. A wrench for screwing pipes into or out of their coupling. See PIPE-TONGS.

Gas-press'ure Reg'u-la'tor. See GAS-REGULATOR.

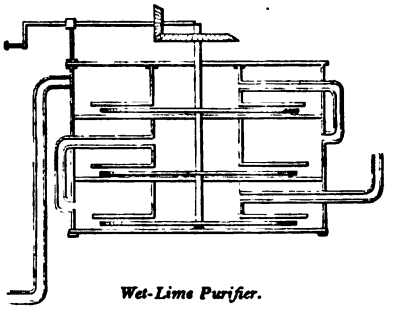
Gas-pu'ri-fi'er. An apparatus in which gas is purified of its sulphur compounds.

The purification of gas by passing it through lime-water is the invention of Mr. Clegg, England, and was introduced in 1807.

The ordinary illuminating gas, after having been evolved in the *retort*, its tar eliminated in the *condenser*, and its ammonia abstracted in the *washer*, is passed through the *purifier*, whose duty is to remove the sulphur and render the gas fit for consumption.

The wet-lime purifier has several chambers containing a certain depth of cream of lime. The gas passes through each chamber in succession, bubbling up through the liquid, the contact being rendered more intimate by arms which rotate in the spaces through which the gas passes in flowing from one chamber to another. The arms also stir up the lime and prevent its settling.

Fig. 2184.



Wet-Lime Purifier.

The cream of lime absorbs the sulphureted hydrogen and carbonic acid, the water absorbs the remaining ammonia.

This process has been generally abandoned on account of the difficulty of disposing of the foul cream of lime known as "blue billy."

In the *dry-lime process* slightly moist hydrate of lime is placed on trays, or iron boxes, through which the gas is made to pass. This process is very effective, and has very generally superseded the wet-lime process. It removes the sulphur compounds and the carbonic acid equally well. When the foul lime is removed, however, it evolves the same odor of sulphide of ammonium which caused the wet-lime process to be abandoned. The suppression of this offensive odor has been effected by washing and special purification. The dry-lime meter has been generally abandoned in Europe, however, as was the wet-lime process previously.

The Laming process, now used in Paris, and generally over the continent of Europe, was introduced in 1849. The hydrated sesquioxide of iron forms a substitute for the lime. It is prepared of a

Digitized by Google

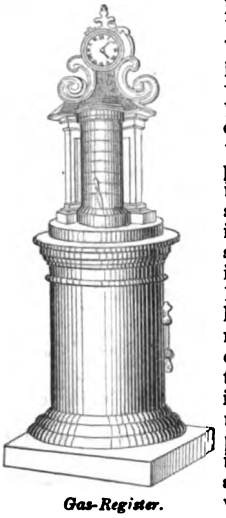
suitable quality by mixing copperas (sulphate of iron) with slacked lime and sawdust, and exposing the mixture to the air to oxidize the protoxide of iron to the sesquioxide. The resulting mixture contains hydrated sesquioxide of iron, sulphate of lime, and sawdust. When an excess of hydrate of lime is employed, the resulting mixture contains this substance also. This material is very effective in removing the sulphur compounds from the gas, and is not offensive when fouled with sulphur. The latter may be distilled to produce sulphuric acid.

The *iron-ore process* of Hill consists in the use of the natural hydrated sesquioxide of iron or bog iron ore, to which is added by the New York Gas-Light Company a quantity of iron borings and turnings moistened by ammoniacal liquor and exposed to the air. To the mixture is added pulverized charcoal. Other ores are used in Germany, where the oxides of iron are used in purification, to the exclusion of all the lime processes.

In some forms of apparatus for the purification of gases which are led through a liquid, a wheel with fans is made to revolve and keep the liquid agitated, while also exposing a large wetted surface to the passing gas.

Gas-reg'is-ter. An instrument by which the pressure of gas is indicated and recorded. The rate of pressure is not uniform, but varies with the season and the hour. An ordinary pressure during the day is $\frac{8}{10}$ of an inch; that is, a pressure which will raise a column of water in a tube to that hight. At night the pressure is increased according to the hour and the season; the quantity burned in winter is double that consumed in summer; more gas is burning at 9 P. M. than at 12 P. M.; and more at the latter than at 3 A. M. The rate being determined according to the judgment of the engineer, a man is placed in attendance, and a register records his doings. This pressure indicator is a cylinder covered with paper and revolved by clock-work. Against it rests the point of a pencil, which is acted on by the pressure of the gas in the mains, and records in a rising and falling line the changes in the pressure, while the vertical graduations of the paper answer to periods of time.

Fig. 2185.



Gas-Register.

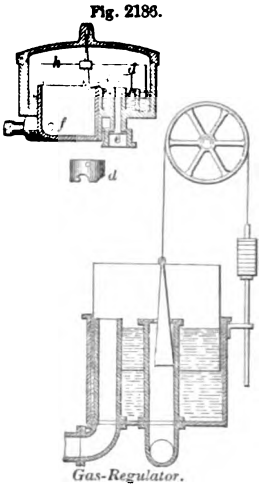
Gas-reg'u-la'tor. A device to equalize the flow of gas, notwithstanding varying pressure in the *main* and the variations produced by turning on or shutting off gas to or from burners in the building.

The valve *d* of the regulator is a cup with a notched rim inverted over the end of the inlet pipe *e* and connected by a lever with a larger cup *h*. The edges of cup *h* and valve *d* dip into annular troughs containing mercury.

As the pressure of gas increases, it acts upon the inside of the cup *h*, causing a depression of the notched edge of the valve *d* into the quicksilver. This decreases the opening through which gas can pass to the delivery pipe *f* in such proportion that at the extra pressure and speed an equal quantity will flow.

A decrease of pressure has a contrary effect, increasing the opening. The pressure of gas is beneath both the valve and the cup, but the latter being the larger overcomes the smaller and drives its edge into the quicksilver.

Fig. 2186.

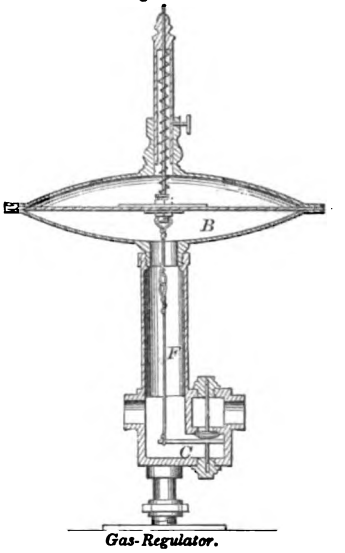


Gas-Regulator.

The larger view, Fig. 2186, has also an inverted cylinder which is partially counterpoised by a weight. As the pressure of gas at the inlet increases, the cylinder rises and carries with it the cone, which contracts the area of the gas opening in the plate on the summit of the central inlet-pipe; the pipe on the left is the exit.

Fig. 2187 shows a rubber diaphragm in a chamber wherein the pressure of gas raises the wire *F* and with it the lever *C* on which is the valve. Thus the extent of pressure in *B* determines the position of the valve relatively to its seat, and this graduates the area of opening to the pressure.

Fig. 2187.



Gas-Regulator.

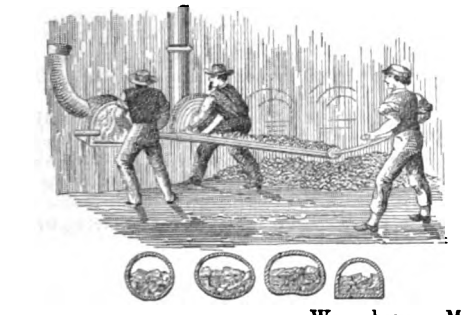
Gas-re-tort'. The chamber in which carbonaceous matter is distilled to produce illuminating gas.

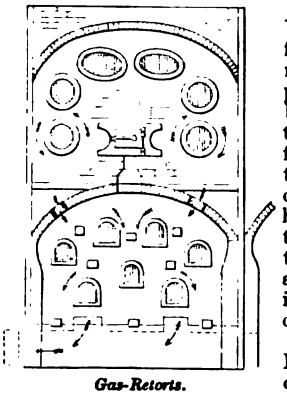
Dr. Clayton distilled illuminating gas from coal in 1688; the "Philosophical Transactions" of 1739 refer to the fact. Dr. Hales in 1726 made a quantitative experiment as to the cubic inches of gas obtained from a given number of grains of coal. Lord Dundonald's patent of 1786 was for ovens or retorts in which coal was distilled. Murdoch in 1792 made lighting buildings by gas a success. See GAS.

Gas-retorts are made of iron or clay, and each in shape is a segment of a cylinder, the flat side forming the floor. These are set in a brick furnace, with their open ends presented outward ready for charging. This is quickly done by a peculiarly shaped scoop, which holds, say, 110 pounds of coal, and is handled by three men, as seen in the illustration. Being introduced longitudinally into the retort, it is upset, and deposits its load on the floor of the retort; a second scoopful makes up the charge, and the mouth of the retort is then closed and luted to prevent the escape of gas.

Digitized by Google

Fig. 2188.





Gas-Retorts.

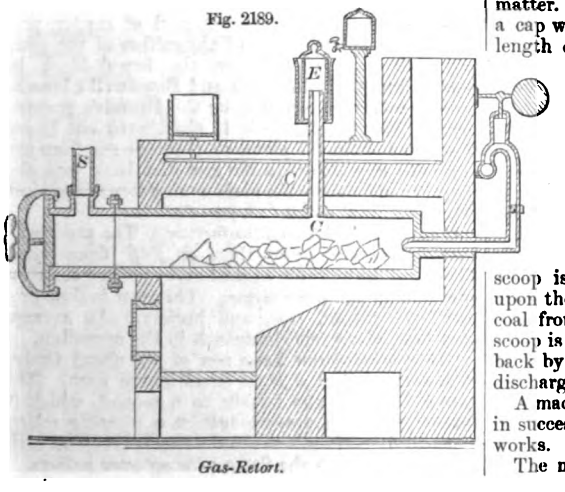
We have Mr. Watson's authority for stating that a retort holds 220 pounds, and that a bench of fifteen retorts is charged in fifteen minutes by three hands. The charge remains five hours in the retort; the coal is expanded to double its bulk and forms coke, but is much lighter, of course.

Some retorts are D-shaped in section, others are oval, and one is noticed having what is called a kidney shape, that is, a general elliptical form is varied by a longitudinal ridge along the bottom.

Croll's gas-furnace, Bow Common, London, England, has an upper series of 6 clay retorts, 18 feet long, constructed to be charged from both ends. The fire has a middle position, and the upper series are heated by the direct radiation from the fire, while the 7 lower retorts of iron, also double, are heated by the caloric current descending from the upper portion of the furnace.

The upper clay retorts are charged every four hours, and the lower iron ones every six hours. The average yield per day is 8,500 cubic feet per retort; $8,500 \times 13 = 110,500$ feet. Twelve of these furnaces are used at the Central Gas-Works, Bow Common, London, having a capacity for 1,326,000 cubic feet daily. The usual make of gas at these works is 900,000 cubic feet per day.

Fig. 2189.

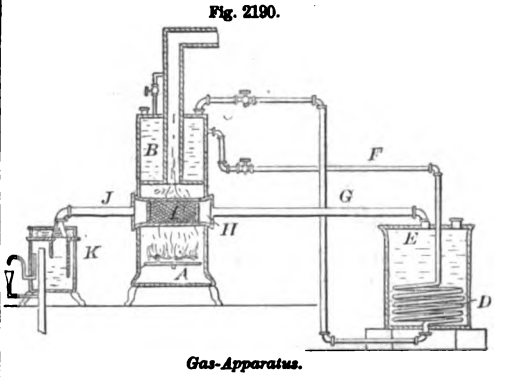


Gas-Retort.

Fig. 2189 shows a retort in which illuminating gas is made from tar introduced from vessel *E* into retort *C*. The tar passes through the water which is contained in the washing vessel above the retort, and which forms an hydraulic stopper to the retort. The steam is generated in pipes over the retort and passes into the latter. The retort is heated to redness and contains coke. A jet of steam is introduced at the rear pipe, and the carbureted hydrogen passes off at *S* to the main.

Fig. 2190 is an arrangement of mechanism for roasting hydrocarbon vapors, or changing them into permanent gases, by exposing them to heat while minutely divided or separated into small streams. The vapors generated in the vaporizer by steam from the boiler pass to the roasting-chamber. The vapor traverses the longitudinal perforations in the charcoal block, and is thus divided into streams to be more effectively acted upon by the heat. It then passes to the condenser.

Fig. 2190.



Gas-Apparatus.

A is the furnace, *B* the boiler, *C* steam-pipe to vaporizer *E*, which contains steam-coil *D*. *G* vapor-pipe to roasting-chamber *H*. *I* charcoal-block, which divides the stream of vapor. *J* pipe leading to condenser *K*.

Fig. 2191 is an arrangement for clearing the inner surface of the retort of the scale of carbonaceous matter. The gas-retort is filled with limestone, and a cap with an air-pipe extending nearly the whole length of the retort is luted thereupon. The cap of the ascension-pipe is removed, and a current of air being established through the retort, the "scurfing," or removal of the carbonaceous coat of the inside of the retort takes place simultaneously with the elimination of carbon from the limestone, producing quicklime.

Gas-re-tort' Charg'er. An apparatus for introducing the charge of coal into a retort or removing the coke therefrom. The scoop is sustained on swivel and sliding bearings upon the truck, which runs on a track, and conveys coal from the heap to the bench of retorts. The scoop is run into the retort, and the bottom is drawn back by the rod extending beneath the handle; this discharges the coal.

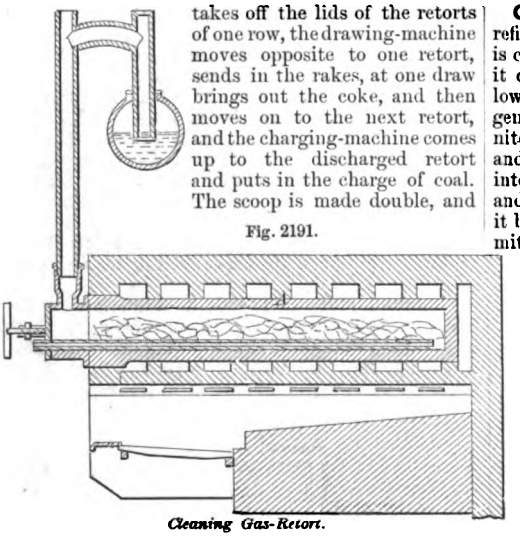
A machine for this purpose has been for some time in successful operation at the Dublin, Ireland, gas-works.

The method of working is as follows: One man

Digitized by Google

takes off the lids of the retorts of one row, the drawing-machine moves opposite to one retort, sends in the rakes, at one draw brings out the coke, and then moves on to the next retort, and the charging-machine comes up to the discharged retort and puts in the charge of coal. The scoop is made double, and

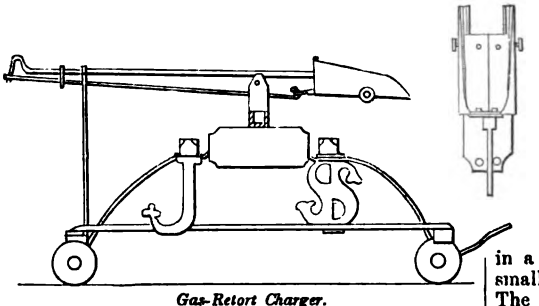
Fig. 2191.



Cleaning Gas-Retort.

forms two small scoops hinged together, and discharging in opposite directions; so that, in turning, the coals are spread well over the surface of the retort, thus utilizing the greatest amount of heating surface in the rein. As the retorts are charged,

Fig. 2192.

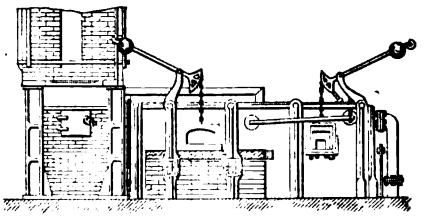


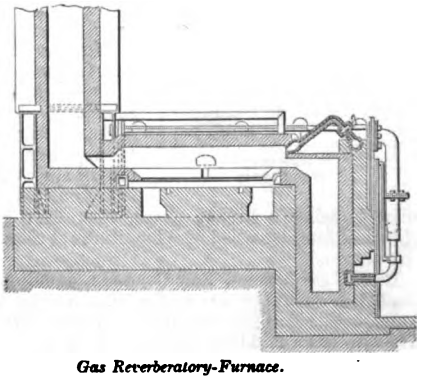
Gas-Retort Charger.

the man who preceded the drawing-machine and took off the lids now follows the charging-machine, closing the retorts. Two boys drive the machines, one man fills the coal into the hopper, and another attends to the taking off and putting on of the lids or doors. The platforms of the machines are now altered to the level of the row of retorts to be drawn and charged next, and those operations proceed as before. By these arrangements, the retorts are exposed to the action of the atmosphere a much shorter time than in the case of hand labor, as the stokers generally "slack out" ten or a dozen doors at once, and draw them all before charging any, thus leaving the first-drawn retort a long time to the cooling atmosphere, whereas with the machine the retort is charged directly it is emptied, — an advantage that must be appreciated by all gas-engineers. The work of drawing and charging is done with a regularity that cannot be attained by manual labor; the retorts are supplied with the maximum quantity of coal they will take, and the quantity does not depend upon the caprice of a scoop-driver. The coke must be raked out clean and a quantity cannot be left in, as is often the case with manual labor when the eye of the foreman is not on the men.

Gas Re-ver'ber-a-to'ry-fur'nace. An iron-refining furnace in which gas from bituminous coal is caused to pass over the molten metal, depriving it of carbon. The upper is a front view, and the lower a longitudinal section of the apparatus. The generator is partially filled with coal which is ignited, a sufficient quantity added to fill the generator, and the opening is bricked up. The metal, broken into pieces of suitable size, is placed upon the hearth, and the inflamed gas is directed downwardly upon it by tuyères. A limited quantity of air is also admitted to the generator by pipes. The metal, when

Fig. 2193.





Gas Reverberatory-Furnace.

in a state of fusion, is stirred occasionally, and a small quantity of limestone added from time to time. The treatment lasts from two and a half to five hours, according to the quality of iron produced, and the metal is drawn off in a fluid state. The fire is allowed to die out, and the generator cleaned at intervals of about fourteen days.

Gas-ring. A thin plate of steel or copper, perforated to the exact size of the caliber of the gun, and used as a face-plate to the breech-block in Sharp's breech-loading rifle and Broadwell's breech-loading ordnance, adopted by the Prussian government. The breech-block is chambered out larger than the hole in the plate, so that the gas from the explosion of a charge in the gun flies back into the chamber and presses the plate or ring forward against the breech of the gun. A *gas-check*.

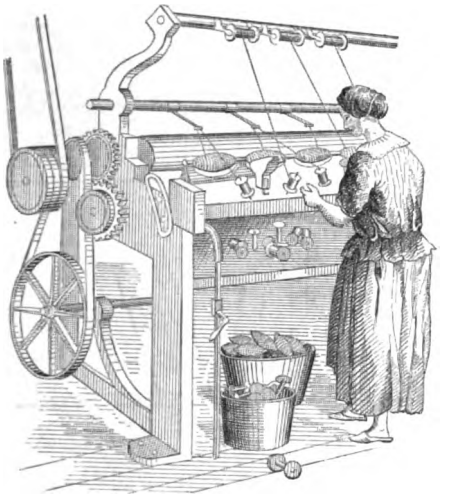
Gas'sing. (*Cotton-manufacture.*) The process of burning the divergent fibers or *fluff* from yarn. The loose filaments are burned off by passing the yarn quickly through a gas-flame. The yarn is thus prepared for thread, lace, and hosiery. An average yarn loses about one eighteenth in the operation.

The *gassing-frame* has a row of jets about twelve inches apart, and a little hood above each. The yarn is led from one bobbin to a second, which is rotated by being pressed against a rotating roller. The yarn in passing between the spools traverses back and forth through the flame passing over pulleys.

Digitized by Google

On emerging from the flame the yarn is cleaned by a brush and passes through a notch in a piece of brass, which is arranged to detect any knot or lump

Fig. 2194.

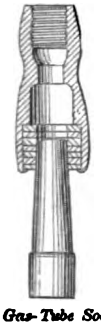


Gassing Yarn.

in the yarn. A defect of this character depresses the brass, and instantly turns aside the gas-burner, so that the yarn is not burnt during the temporary stoppage; the defect being remedied by the minder, the parts are restored to their normal position and the operation proceeds.

Gas-sock'et. The metallic socket which slips over the tip of a burner, and connects the elastic gas-tubing therewith.

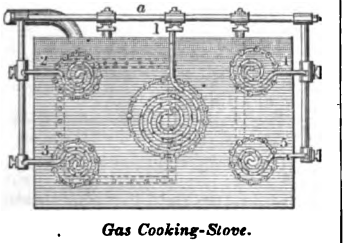
Fig. 2195.



Gas-Tube Socket.

Gas-stove. One usually made of iron, and may be partially lined with fire-brick.

Fig. 2196.

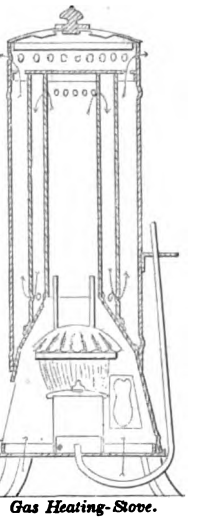


Gas Cooking-Stove.

Branches 1, 2, 3, 4, 5, from the main pipe *a* are carried to the upper part of the stove and to the bottoms of the various interior compartments designed for roasting, baking, etc. These terminate in circularly arranged tubes, provided with minute burners, over which the vessel containing the article to be cooked is supported.

Fig. 2197 is a heating stove in which the gas is turned on to the perforated top of a gas-chamber, and over this a corrugated conical cap is suspended from an upright flue, the product of combustion flowing into and around this cap up the flue, and through holes in the side at top, down another flue as far as the cover of the combustion chamber, and thence through the apertures into and up a third flue to the top of stove. The flues are formed by spaces between three cylinders of different diameter; a plate at the top covering the inner flues has perforations over the outer flue.

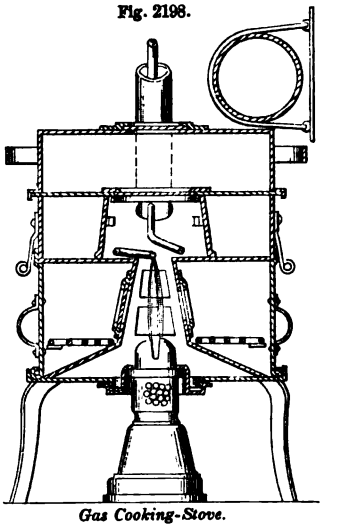
Fig. 2197.



Gas Heating-Stove.

Fig. 2198 is a gas cooking-stove which has a square sheet-iron stove, to be used with a kerosene lamp, or a gas-burner, having on each side an oven for baking, etc., which is surrounded on all sides, except the outside and ends, by a flue, in which the products of combustion circulate. On the top of the stove are holes in which the cooking utensils are placed, and a pan for baking may also be placed thereon. By means of dampers the products of combustion may be prevented from circulating beneath the top, and made to pass directly out of the chimney. On one end of the stove is a boiler in which to generate steam, which is conveyed off by pipes to perform various culinary operations. Pieces of mica are let into the stove in various places to expose the light and also to give a view of the interior of the ovens.

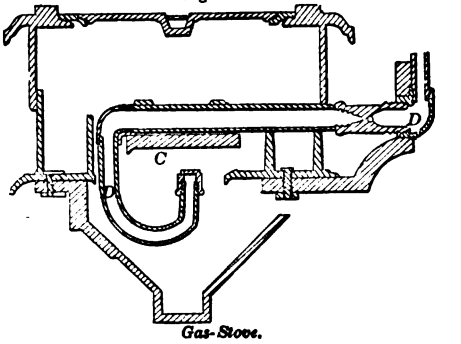
Fig. 2198.



Gas Cooking-Stove.

Fig. 2199 is a gas-stove in which the heat of the burning jet is made to vaporize coal-oil in the pipe *D*. The generating chamber is of a metal less liable to oxidation than cast-iron, and is protected by a movable plate beneath, which is suspended over the surface of the burning hydrocarbon. The heat is concentrated by an annulus *C*, which encloses the combustion chamber. A fire-cup beneath the burner catches the waste oil.

Fig. 2199.



Gas-Stove.

Digitized by Google

Gas-torch. A lighter for gas. See LIGHTING-DEVICES; ELECTROPHORUS.

Gas-wash'er. This apparatus receives the gas from the condenser, which removes the tar. The office of the washer is to remove the ammonia, which affects the quality of the gas and is otherwise injurious. Several forms of washers are known. The essential features consist of devices for bringing every particle of the gas into contact with water, for which the ammonia has a great affinity. The effectiveness of a particular machine is in proportion to the intimateness of the contact of the gas and water therein. Dr. Watson, Bishop of Llandaff, announced the fact in 1750, that the inflammability of gas was not affected by contact with water. The *washer* is the third in the series of gas-making apparatus. (See GAS-MAKING.) Mr. Croll, an English gas-engineer, is credited with the invention of the gas-washer now in use.

Eight or ten gallons of ammoniacal liquor are extracted from the gas produced from 2,000 pounds of coal, and it is treated by manufacturing chemists, who extract about fourteen ounces of sulphate of ammonia from one gallon of the liquor.

Gas Weld'ing-fur'nace. (*Metal-working.*) A heating jet, or cluster of jets, to heat pieces of metal locally, in order to bring them to a welding temperature. See GAS BLOW-PIPE.

Gate. 1. A barrier which may be opened to permit passage; as, —

Canal-lock gate.	Sluice-gate.
Farm-gate.	Turnpike-gate.
Flood-gate.	Water-gate.

Some of which are considered under their alphabetical order.

a is a gate with adjustable hinges, operating on rings on the post; the fastening consisting of a movable latch and staple.

b shows a mode of setting up the gate when the outer end sags, by means of the diagonal strut.

c shows another form of setting up the outer end by means of a tie slat.

d is a gate whose top bar is pivoted on the post, the gate being counterweighted by a box of stone on the extended bar.

e is a gate which slides longitudinally, its slats traversing on rollers.

f is also a sliding-gate, which has rollers to keep it level, whether open or shut.

g is a gate which slides half its length and then rotates on a bar at its midlength.

h is a gate of pivoted bars on the principle of the lazy-tongs.

i is a gate having a set of pivoted slats, which assume a vertical position when the counterweighted top slat is allowed to oscillate.

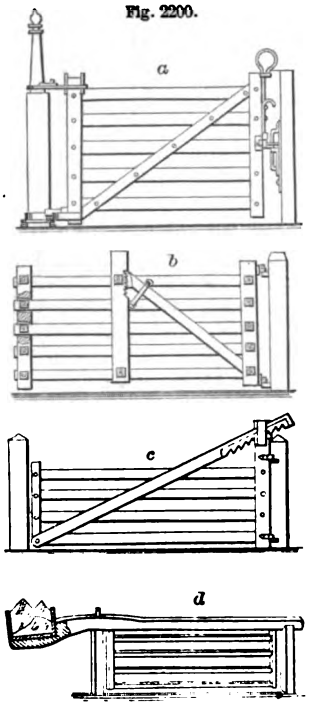
j is a suspended gate, which swings upward broadside in a vertical plane.

k is a gate suspended from pulleys, and counterweighted.

l m are gates operated by equestrians or persons in vehicles by means of ropes.

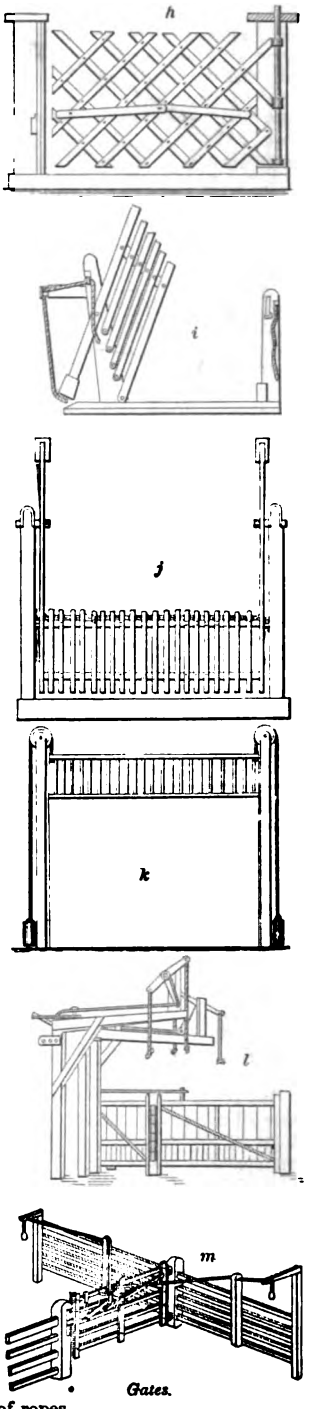
2. (*Locksmithing.*) One of the apertures in the *tumblers* for the passage of the *stub*.

Fig. 2200.



Gates.

Fig. 2201.



Gates.

Digitized by Google

3. The valve which admits the water to the bucket of the WATER-WHEEL (which see).

4. (*Founding.*) *a.* An *ingate.* The aperture in a mold through which the metal is poured. The *runner* conducts the metal from the *ingate* to the hollow in the mold, where it forms a *casting.* The piece of metal which occupies the *ingate* and *runner* is called a *sprue*, and is knocked off the casting.

b. The sprue or piece of metal cast in the gate. A sullage-piece.

Gate-cham'ber. (*Hydraulic Engineering.*) A recess in the side wall of a canal-lock, which receives the opened gate, so that it shall not project into the lock-chamber.

Gate-chan'nel. (*Founding.*) The *gate, geat,* or *git,* through which molten metal is admitted to the mold. See GATE.

Gate-hook. A gate-hook is that part of a gate-hinge which is driven into the post and sustains the leaf attached to the gate.

Gate-post. One to which a gate is hung or which it shuts against, and which are known respectively as the *swinging* or *hinging* post, and the *shutting* post.

Gate-saw. A mill-saw which is strained in a *gate* or *sash* to prevent *buckling.*

Gate-shut'ter. (*Founding.*) A spade or paddle which closes the channel against the molten metal when the mold or bed is full, and turns it in another direction to other molds or beds.

Gath'er. 1. (*Vehicle.*) The inclination forward of an axle journal, or spindle, usually one tenth of its diameter.

The amount of gather depends upon the amount of taper. A perfectly cylindrical spindle requires none.

The inclination downward is also dependent upon the taper, and is called the *swing.* The latter renders the *dishing* of the wheel necessary, in order that each spoke as it comes to the bottom position may be vertical. See SWING; DISH.

If a taper spindle be made without any *gather,* the tendency of the wheel is to slip outward against the linchpin or nut. If the *gather* is in excess, the *boxing* of the *hub* rubs hard against the *butting-ring* of the axle.

2. (*Bookbinding.*) To collect and place in consecutive order the printed sheets of a book. The pile of sheets is *folded, gathered, collated, stitched,* and *bound.*

3. (*Needlework.*) To draw into plaits or folds by means of a thread or cord.

Gath'er-er. (*Sewing-machine.*) A device which brings the cloth together in folds or plaits, so as to be sewn in crimps. It may consist of a tongue whose end pushes against and puckers up the material in advance of the action of the needle. In the example, Fig. 2202, the device is attached to the presser foot.

Fig. 2202.

Gatherer.

The upper and lower pieces of cloth are separated by a metallic tongue, so that the feed-bar acts first upon the lower piece and gathers the same. The two pieces of cloth are then forwarded together beneath the presser.

There are numerous varieties. See Gregory's "Sewing-Machine Attachments," Washington, 1872. The ruffler acts upon the same principle.

Gath'er-ing. 1. (*Bookbinding.*) The selection and arranging of a set of sheets according to signatures, to form a book. See GATHER.

2. (*Carpentry.*) An assemblage of beams supporting a scuttle.

Gath'er-ing-board. (*Bookbinding.*) A horse-shoe-shaped table on which signatures are laid to be gathered or assembled to form a book. A more convenient way is to arrange the signatures on a long straight table, the first half on one side and the latter half on the other, so that the gatherers may follow each other consecutively, "knocking up" and depositing the complete book on an adjoining table.

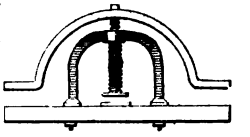
Gath'er-ing-hoop. One used by coopers to draw in the ends of the staves so as to allow the hoop to be slipped thereon.

Gat'ling-gun. A machine-gun which has a cluster of barrels and a charging breech at which the cartridges are automatically loaded into the barrels and fired in succession. See BATTERY-GUN.

Gau-din'o-type. (*Photography.*) A process named from its French discoverer, Gaudin.

Gauf'fer-ing-press. A press in which pieces of fabric cut to the shapes of leaves, petals, etc., are pressed between dies to confer the ridges, indentations, creases, and other irregular features of the natural object.

Fig. 2203.



Gauffering-Press.

The ancient Egyptians gauffered their linen by pressing it between fluted boards.

Gauf'fer-ing-tool. A tool for giving the roundness, fluting, crimping, or other peculiar form to leaves, petals, calyxes, etc., for the construction of artificial flowers and sprays.

The hand tools are spherical, conical, pyramidal, hooking, or cylindrical, and attached to handles, the working faces being heated to deliver the impression or indentation.

Other tools are stamps with counterpart convex and intaglio faces, between which is stamped the piece of fabric which has been previously cut to a shape.

The material is cambric, jaconet, and fine muslin, crape, gauze, taffeta, satin, and velvet, according to the natural appearance of the flower represented.

Various other materials are necessary, — silk thread, wire, wax, beads, floss-silk, chenille, gum-water, starch, gold-leaf, kid, colors, nap of cloth, etc.

Gauge. A measuring device. See GAGE.

Gaunt'let. An armed glove, anciently of mail or leather, with metallic shells or scales.

Gaun'tree; Gawn'tree. A trestle for casks.

Gauze. (*Fabric.*) A light, transparent silk or cotton goods. Said to be named from Gaza, in Palestine, from whence it was introduced.

In gauze-weaving, between every two casts of the shuttle, the warp-threads are turned or twisted after receiving the woof from right to left, and the reverse, alternately, between each throw of the shuttle, so that the weft threads, represented by black dots in the figure are separated from each other, and a light, transparent texture produced.

Fig. 2204

Gauze-Weaving.

Gauze Wire-cloth. A textile fabric, either plain or twilled, made of brass, iron, or copper wire, of various degrees of fineness. Used for sieves, safety-lamps, respirators, etc. Brass-wire gauze was shown in the French department of the London

Digitized by Google

Exhibition of 1851, having 67,600 meshes to the square inch = 260 parallel threads in a linear inch.

Gav'el. 1. Originally, a small parcel of grain in the straw. Now, enough of the grain to be bound into a sheaf; the grain is raked from the harvester platform in *gavels*. Binding makes it a *sheaf*. A stook, or collection of sheaves placed on end, leaning together and mutually supporting, is a *shock*.

2. A mason's setting maul.

3. A presiding officer's mallet.

Gav'e-lock. An iron crow-bar.

Gay'di-ang. A vessel of Anam resembling a junk. It carries two or three masts with triangular sails.

Gaze-a-Blu-toir'. (*Fabric.*) A thin silk gauze, made in France, for bolting cloths.

Gaz-o-gene'. A portable fountain or soda-water apparatus. See Fig. 45, p. 18.

Ga-zon'. (*Fortification.*) A piece of sod used as a revetment or lining for parapets and earthen banks.

Gear. A general term which may mean: —

1. Arms ("ready all his *gere*," Chaucer), *accouterments* ("armours and al other *gere*, *Ywaine and Gawin*," Ritson), *clothing*, *dress*, *trappings*, *harness*, *chafing*-gear.

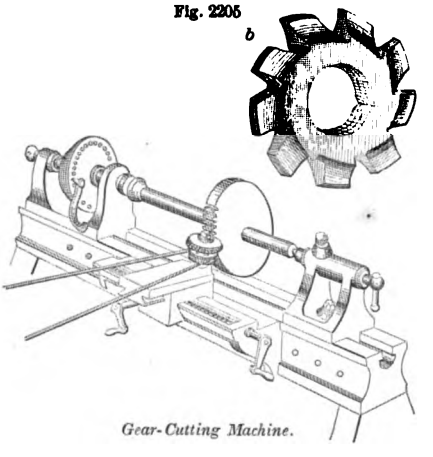
2. Furniture, rigging, tackle (*jeers*), apparatus, the appurtenances of an implement: e. g., *expansion*-gear, *valve*-gear, *pump*-gear, *plow*-gear; the working parts of a locomotive; the rigging of a spar or sail; the running parts of a wheeled vehicle, as the *fore-gears*, *hind-gears*, referring to the *fore*-axle and its wheels, the *hind*-axle and its wheels. To the former is attached the tongue and fore hounds, to the latter the hind hounds. Each carries its bolster.

3. A cog-wheel. See GEARING.

Gear-cut'ting Ma-chine'. One for making cog-wheels by cutting out the interdental material. Invented by Henry Maudslay.

In one form of this machine, the disk to be cut is fixed on a spindle or mandrel, to whose end is attached a graduated dividing-wheel. This wheel has a number of circles, each having its own series of graduations, at which are holes with which the stop-pin engages to hold the blank while the circular cutter on the slide-rest does its work. This cutter has a shape coinciding with that of the interdental space of the wheel required, as shown in the enlarged view *b*. The mandrel of the cutter-wheel is rotated by a band, and the cutter is fed by a hand-crank and feed-screw, so as to traverse past the face of the wheel under treatment.

Fig. 2205



Gear-Cutting Machine.

The face of the dividing-wheel, as has been stated, has various circles of graduations, which afford the means of giving a great choice of number of cogs to the wheel on the spindle.

Circles graduated as below are divisible by the numbers attached, and divide a wheel for the corresponding numbers of teeth: —

Number of teeth.	Graduations.										
	192	200	208	216	220	224	252	256	272	304	360

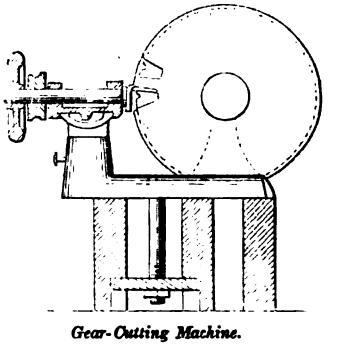
Fig. 2206 shows a machine for cutting wooden gear, or patterns of cog-wheels for casting. Arranged on a lathe-bench is a sliding cutter-carriage, having a revolving cutter of the shape of the side of the tooth, so that as it revolves it cuts the space between two teeth; a graduated dividing-plate governs the spaces between the teeth.

Fig. 2206.



Gear-Cutting Machine.

Gear'ing. Wheels with cogs to transmit power.

The term is also applied to other mechanical devices by which motion is transmitted; as, *change-gear*, *chain-gear*, *back-gear*, *overhead-gear*; or by which parts are operated, as *valve-gear*, *hoisting-gear*, *expansion-gear*. Also to other devices involving an assemblage of parts, as *running-gear* of a wagon.

Archimedes was acquainted with toothed wheel-work before the Christian era.

Thomas Young does not doubt that Ebn-Junis, at the end of the tenth century, had applied the pendulum to the measurement of time, but ascribes the first combination of the pendulum with wheel-work to Santorio, in 1612.

The hydraulic clock of Ctesibus, under Ptolemy Euergetes II., which gave the civil hours throughout the year at Alexandria, was, according to the description of Vitruvius, a real astronomical clock; a very complicated hydraulic machine, working by means of toothed wheels. It is not improbable that the

Digitized by Google

clock presented by Haroun al Raschid to Charlemagne, and which marked the hours by the sound of small balls falling, and also by the appearance of miniature horsemen through doors, was analogous in principle.

See under the following heads: —

Gear'ing-chain. An endless chain transmitting motion from one toothed wheel to another.

Gears. A name applied to harness, as the clothing (Anglo-Saxon, *geara*, clothing) of a horse. The word is usual in the West, and different kinds of harness are indicated by the names *single-gear*, *double-gear*, *lead-gear*, *hip-strap gear*, *Yankee-gear*, etc.

Gear-wheel. Any cog-wheel, whether crown, spur, internal-cogged, bevel, or lantern, is a gear-wheel. The essential feature is the possession of cogs, which act upon the cogs of another wheel in the train or series to impart or transmit motion. See GEARING.

Geat. (*Founding.*) The channel or spout through which molten metal descends into the mold. See GATE.

Geis'ler-tube. A sealed tube filled with rarefied gas, through which an electric spark is transmitted by means of platinum connections inserted at each extremity. On the passage of the spark, waves and bands of light make their appearance, which range in color and intensity according to the character of the gas with which the tube is filled. This apparatus is used with the induction-coil.

Gel'a-tine. An animal substance which assumes several forms, according to the material from which it is made and the mode of manufacture.

Common gelatine is made from clippings of hides, horns, hoofs; and some is yielded by the feet, bones, tendons, and ligaments of animals.

In a jelly form it is called *size*.

The coarser qualities, dried in flakes, are *glue*.

When made from the membrane of fishes it is *isinglass*, the best of which is made in Russia from the air-bladders and sounds of sturgeon.

Gel'a-tine-pro'cess. The action which is at the bottom of nearly all the permanent photographic-printing processes is that of light on gelatine in presence of a bichromate. Dissolve gelatine in hot water, and add to the solution some bichromate of potash, and dry it; the compound is sensitive to light in a way different from ordinary photographic paper. Exposure to light changes the color to a chestnut-brown, but, what is more important, it is no longer soluble in hot water. If a portion of the dried gelatine and bichromate be shielded from light, that portion will dissolve as readily as before, but the portion which has been acted on by light forms a tough, tawny substance which is unaffected by the hot water. The discovery of this action was made in various steps, the first change of color being announced by Mr. Mungo Ponton as early as 1839. This remarkable property was finally laid hold of by experimentalists, and two groups of processes have been founded upon it. In the first group, this action is brought into play in the production of every proof. That is to say, every picture is produced by the action of light on bichromated gelatine. In the second group, one picture is produced by the action of light on bichromated gelatine; and this picture is made by various devices to serve as a printing matrix, from which any number of impressions may be struck off by mechanical means.

In the first group is included what is ordinarily called CARBON-PRINTING (which see). See also AUTOTYPE.

In the second group, the gelatine picture is used as a matrix for producing a printing-base, or is itself used as a printing-base, which is then in either case printed from by mechanical means. The first successful attempts in this direction resulted in the process which is known as photolithography. A print is produced by the action of light on paper coated with sensitized gelatine in the way first indicated. It is found that lithographic ink will adhere to those parts where light has acted. The gelatine print is accordingly inked with a lithographic transfer-ink, and the print thus produced is transferred to the surface of stone or zinc. But a lithographic stone does not do more than discriminate between black and white; it will not recognize half-tones. The process is therefore only suitable for the production of work either in dots or lines. For this purpose it was used by Mr. Osborne in Australia, in Southampton, England, and now very extensively in this country. See PHOTOLITHOGRAPHY.

Poitevin's process, 1855, belongs to this group, and is typical of its kind. He coated the stone with bichromated albumen, and put it through the actinic processes *in situ*, then inked up on the stone.

Another process in the second group is PHOTOGALVANOGRAPHY (which see). See also PHOTOGLYPHIC ENGRAVING; PHOTOZINCOGRAPH.

A third process is the *Woodbury*, in which a gelatine picture, having been obtained by light, is placed in contact with a sheet of soft metal, and submitted to heavy hydraulic pressure. Bearing in mind that the gelatine picture is a picture in relief

Digitized by Google

and depression, the metallic counterpart obtained by pressure will be in reversed relief and depression. A mold will have been obtained, which it will only be necessary to fill with a solution of gelatine to obtain a duplicate, so to speak, of the gelatine picture from which the metallic mold was struck. The resulting picture will be one in relief and depression; but if, as in the case of carbon-printing, coloring matter is mixed with the solution of gelatine used to fill the metallic molds, it will also be in light and shade. A little solution of gelatine in hot water, containing suitable coloring matter, is poured into the metallic mold, a piece of paper is placed on the top, and a level lid pressed down on it, so as to squeeze out superfluous gelatine. In a few minutes the lid is opened and the paper removed, bringing with it the adhering gelatine, which, with the coloring matter, forms the picture. See WOODBURY PROCESS; NATURE-PRINTING; HELIOTYPE; ALBERTYPE, — so named from Herr Albert of Munich.

Gem. A precious stone, as a diamond, ruby, sapphire, emerald, topaz, opal, etc. Some of those in the following list are only semi-precious, and are not strictly gems. In a mechanical point of view, they have about equal interest. Some common and softer minerals are introduced for the sake of comparison.

Table of Hardness of Gems, etc.

Agate	12	Onyx	12
Amethyst	11	Opal	10
Calcareous spar	6	Quartz	10
Chalk	3	Ruby	16 – 17
Crysolite	10	Ruby spinelle	13
Carnelian	11	Sapphire	16 – 17
Crystal	11	Sardonyx	12
Diamond	18 – 20	Schorl	10
Emerald	12	Topaz	11 – 15
Fluor-spar	7	Tourmaline	10
Gypsum	5	Zeolite	8
Jasper	9 – 11		

Gem, Ar'ti-fi'cial. Factitious stones are made of very pure, fusible, highly transparent, and dense glass, usually called *paste* or *strass*. The composition is silica, potassa, and oxide of lead, with some other ingredients at times, and metallic oxides for coloring. (See GLASS-COLORING.) The beauty depends upon the clearness and the exact imitation of the natural gem, and also upon the care and skill in the cutting.

Gem-cut'ting. The surfaces of gems are cut into facets to increase their brilliancy. The greater the natural brilliancy the fewer facets are required to obtain a given brilliancy.

As a general rule, the back that is inclosed in the setting has double the depth of the face. The back is cut into facets or squares that exactly correspond in place with the position of the principal facets on the front of the stone; and the angles which the squares at the back make with the axis of the stone are required to be such that all the light reflected from their surfaces may fall within the central, flat surface, on the part of the stone called the *table*.

The parts of a cut gem are as follows: —

Front; the face or exposed portion.

Back; the rear portion.

Table; the central plane in the face.

Girdle; the extreme margin of a stone by which it is retained in the setting.

Top; the beveled portion between the *table* and the girdle.

Facet; a small face.

Cullet; a small central plane on the back.

See BRILLIANT.

Gem-cutting was not so well understood among the ancients as it is now, neither are the Oriental cutters equal to those of Amsterdam. The *Koh-i-noor* was recut after coming into the possession of the British queen. (See DIAMOND.) We read, however, of gem-cutting in Pliny and elsewhere.

"People bore into these red hyancinths (rubies) by means of the diamond." — AL KHÂZINÎ, 12th century.

The principal modes of cutting may be classed under three heads: —

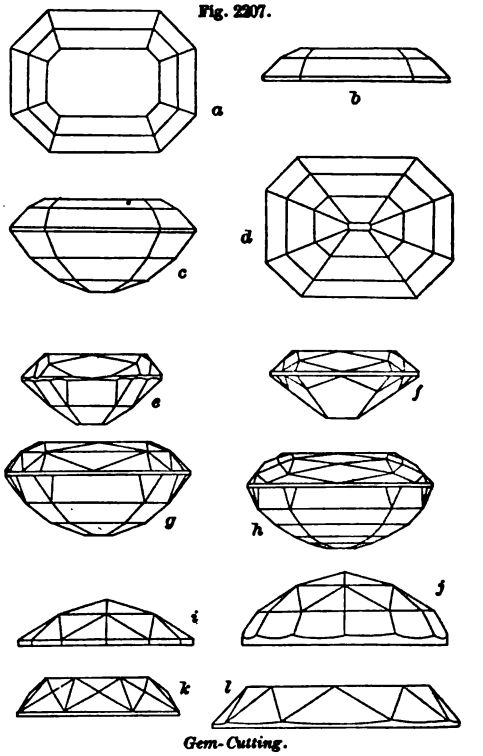
The *trap*, *brilliant*, and *rose cut*.

The *trap* (*a b*) *cut* consists of parallel planes nearly rectangularly arranged around the contour of the stone.

c d represents a thicker stone, trapped in two hights on the front and three on the back.

The *brilliant cut* consists of lozenge-shaped facets alternating with triangles, and is used for the fronts

Fig. 2207.



Gem-Cutting.

of most transparent stones that are sufficiently thick to allow of being cut into facets on both the front and the back.

There are several varieties of brilliant cuts, known as —

Half-brilliant *e*.

Full-brilliant *f*.

Split or trap brilliant *g*.

Double-brilliant or Lisbon cut *h*.

The *rose cut* (*i j*) consists of triangular facets arranged upon and around a central hexagon. This cut is employed upon such stones as are thin and large on the surface, as the rose cut is only applied on the surface and the back is left flat. The rose cut is considered to give the greatest luster that can be obtained from cutting the front only, as the surface is entirely covered with facets.

Digitized by Google

k is the X-cut; *l*, dental cut. Many other minor varieties might be cited.

Gem'el-hinge. (*Locksmithing.*) (Lat., *gemellus*, twin.) A hinge consisting of an eye or loop and a hook.

Gem'el-win'dow. (*Architecture.*) A window with two bays.

Gem-en-grav'ing. The art of engraving on gems. It is performed by small revolving wheels or points charged with diamond dust, emery, etc., according to the hardness of the gem. See SEAL-ENGRAVING.

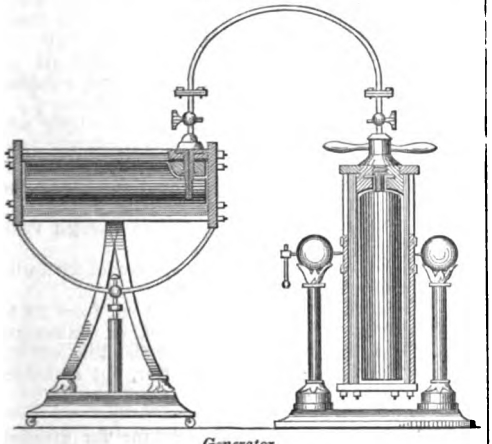
Gen'der. (*Music.*) A Javanese musical instrument introduced into England by Sir Stamford Raffles. It consists of a row of parallel metallic plates, supported horizontally by two strings passed through the respective nodal lines of the plates. The modern dulcimer with glass plates supported on tapes gives an idea of the method. Underneath each plate is an upright bamboo containing a column of air of such a length as to reciprocate the sound of the plate above. The resonance of the unisonant columns of air augments the sounds of the vibrating metallic plates.

Gen'er-at'ing-sur'face. The heating surface of a boiler, that on which heat is applied to generate steam.

Gen'er-a'tor. 1. (*Steam.*) A vessel in which steam is generated from water, for use in a steam-engine, a heating apparatus, etc. The term was first applied to the Perkins steam-boiler, in which water in small quantity was heated to great temperature. It is now specifically applied to a class of instantaneous generators. The name is now rapidly coming into use for all apparatus for generating steam, being held to be more correct than the usual term. See STEAM-BOILER.

2. (*Aërated Waters.*) An apparatus for generating carbonic-acid gas for charging soda-fountains, or

Fig. 2208.



Generator.

bottles with aërated water. One form is shown in the figure. The generator (shown on the right) is a lead-lined copper cylinder, supported on an axis, and containing the ingredients, which may be water, carbonate of lime, and sulphuric acid, which are commingled by the swaying or reversal of the chamber on its axis. The gas evolved passes to the receiver, where it is absorbed by the water, assisted by the swaying of the receiver on its axis. See AËRATOR, pp. 18–20.

3. A retort in which volatile hydrocarbons are distilled from solid or liquid matters. See GAS-MAKING; GAS-GENERATOR.

Ge'o-met'ric-al Lathe. An instrument belonging to the bank-note engraver. Like the CYCLOIDAL-ENGINE (which see), it is used for making complicated patterns of interlacing lines to form an additional guard against counterfeiting. It is adapted for more delicate and minute work than the cycloidal engine, and is the means by which the stars, rosettes, and ornamental tablets, escutcheons and borders, are produced around the denominating figures, etc., of bank-notes.

A graver whose normal motion is in a curve is made by the motion of the plate to form a waved line with any character of convolutions; this is crossed by one of somewhat varying character, and this by a third, and so on, forming an interlacing but regular pattern. If the plate move in a direct line, this pattern will have a general straight direction, but if the plate be moved in a circle, a circular pattern of interlacing lines will be the result. By cams and other devices the general trend of the figure may be made to fill a circle, ellipse, shield, or tablet of any form. Fair examples of the work may be seen on the face and back of the greenbacks of the United States, and it will be seen that the spaces and escutcheons consist of a series of concentric designs.

Machines of this character are very costly, and possessed by but few establishments; the Treasury of the United States and the American Bank-Note Company for instances. The difficulty of counterfeiting is much increased by the use of this mode of ornamentation.

Ge'o-met'ric-al Pen. An instrument for drawing geometric curves, in which the movements of a pen or pencil attached to a revolving arm of adjustable length are varied by changing the toothed wheels which give motion to the arm. — WEBSTER.

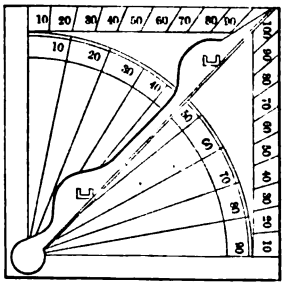
Ge'o-met'ric-al Ra'dius. (*Gearing.*) The radius of the pitch circle of a cog-wheel. The *real* radius is that touching the crests of the teeth.

Ge'o-met'ric-al Stairs. A stone stairs where the steps are secured into the wall at one end only, the other forming a continued string with an open newel.

Ge'o-met'ric Chuck. A chuck having a radial slider to which the work is attached, the said slider oscillating in a plane at right angles to the axis of motion, so as to produce curved lines in various patterns, as regulated by special devices. See GEOMETRIC LATHE; ROSE ENGINE-LATHE.

Ge'o-met'ric Square. An instrument for measuring distances and hights, and useful for its portability as well as for the facility, by the common rule of three, of solving most of the problems arising from its use. It is made of brass or wood, 12 or 18 inches square, and the quadrant is graduated in each direction. The two sides opposite to the axial point of the alidade are graduated to 100 equal parts, with major divisions of ten of said parts. The 100 point finishes at the angle obliquely opposite the center from which the arc is struck. One side represents the horizon, and the alidade with two sights is equal in length to the diagonal of the square. The alidade has divisions equal to those on the sides of the square.

Fig. 2209.



Geometric Square.

In measuring vertical hights, the distance is

Digitized by Google

measured from the station to the base, and by moving the alidade the angle subtended by the object is observed.

Ge-o-ram'a. A concave globe on the inside of which the countries, oceans, etc., of the earth are represented to the spectators, who stand on a framework inside.

The globe of Gottorp was 11 feet in diameter; that of Dr. Long was 18 feet in diameter. Mr. Wyld's, 1851-61, was 60 feet 4 inches in diameter. The concavity of each of these represented the terrestrial surface.

Wyld's globe was lighted by openings during the day and by gas at night. See GLOBE.

Ge'o-stat'ic Arch. (*Architecture.*) A linear arch of a figure suited to sustain a pressure similar to that of the earth, which consists, in a given vertical plane, of a pair of conjugate pressures, one vertical and proportional to the depth below a given plane, horizontal or sloping; and the other parallel to the horizontal or sloping plane, and bearing to the vertical pressure a certain constant ratio depending on the nature of the material, etc. — RANKINE.

Ge-o-ther-mom'e-ter. An instrument for measuring the earth's heat at different depths, as in mines and wells. The temperature rises about 1° Fah. for every 70 or 80 feet of descent.

Ger'man-bit. A wood-boring tool adapted to be used in a brace. It has a long elliptical pod and a screw-point. See BIT.

Ger'man-chest. (*Metallurgy.*) (*Caisse a tombeau*, coffin.) An apparatus resembling a *trunk* in some respects. It is a long box into which the *slimes* are carried gradually by a stream of water. The heavier portions settle near the head of the box, and the lighter towards the lower end, where the water escapes at holes from which the pegs are withdrawn; a lower peg being replaced and the discharge-opening being made a little higher up as the box gradually fills.

Ger'man-sil'ver. A white alloy for table ware, consisting of nickel, copper, and zinc in various proportions: —

	Nickel.	Zinc.	Copper.	Cadmium.	Iron.	Tin.	Lead.	Antimony.
Brande	1	1	2					
Brande	8	3.5	8					
Parisian	20	5.5	70	4.5				
Packfong (Chinese)	31.6	25.4	40		2.6			
Parke's (Eng. patent, 1844)	45.5	21	91		45.5			
Cutler's (Eng. patent, 1838)	5	5	16		8	1	1	1
Toucas's (Eng. patent, 1856)	4	1	5					

Another authority gives: —

	Nickel.	Zinc.	Copper.
Common albata	3.5	16	20
Best albata	5.5	9	20

Another: —

	Nickel.	Zinc.	Copper.	
German silver (finest quality)	1	2	1	
German silver (for rolling)	25	60	20	Lead.
German silver (for casting)	20	60	20	20
German silver (original formula)	32	40	25	Iron. 3

It is said to have been originally obtained from a metallic ore found at Henneburg, whose analysis is nearly the same as the last formula given above.

Ger'man-steel. A metal made of charcoal-iron obtained from bog-iron or the sparry carbonate.

Ger'man-tu-ta'nia. An alloy of copper, 1; tin, 48; antimony, 4.

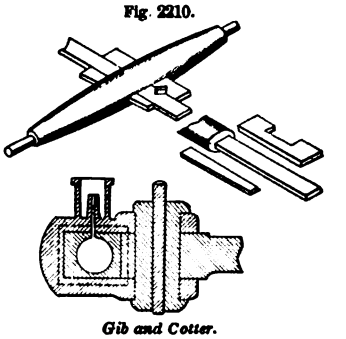
Ger'man White-cop'per. An alloy of copper, 88; nickel, 8.75; with traces of silex, aluminium, antimony, and arsenic.

Get-in. (*Printing.*) An order to condense matter so that it shall not extend beyond the end of a line. *Run in.*

Gi'ant-pow'der. A form of *dynamite*, consisting of infusorial earth saturated with nitro-glycerine. The silicious earth consists of diamtoms and frustules, and the result is a brown powder, something like fine sawdust.

Gib. A piece of metal or wood whose duty it is to hold another in place, as in the case of a sled-tongue in its roller, or a strap-head on a connecting-rod. See KEY.

Fig. 2210.



Gib and Cotter.

It is usually tightened by a key or cotter, as in the annexed illustration, which shows a very common mode of securing the tongue in the roller of a sled. The notched *gib* is placed in the mortise of the *roller*, the *heel of the tongue* inserted, and a wedge-shaped *cotter* is driven in to tighten them all in place. Pins prevent the endwise withdrawal of the *tongue* or *cotter*.

Gib. 1. *Gib and key.* The fixed wedge and the driving wedge for tightening the strap which holds the brasses at the end of a connecting-rod in steam machinery. See lower illustration in Fig. 2210.

2. The projecting arm of a crane. *Gibbet, jib.*

Gib'bet. The post and arm of a crane, reaching over for the suspension of the load therefrom.

Giffard In-ject'or. A steam-jet which acts upon a body of water by which it is condensed, and to which it communicates its velocity, driving it through the feed-water pipe into the boiler. See INJECTOR.

Gig. 1. (*Vehicle.*) A light, two-wheeled vehicle, drawn by one horse.

2. (*Fabric.*) A rotary cylinder covered with wire teeth for *teaseling* cloth.

3. (*Nautical.*) A clinker-built boat, from 20 to 28 feet long, and rowed with 4, 6, or 8 alternate oars. It is reserved for the commanding officer. Usually nearly the size of the cutter, but of longer and slenderer build.

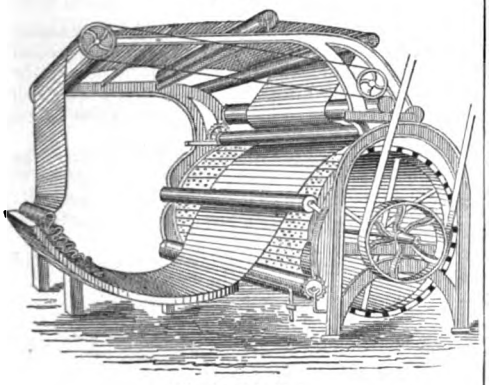
4. A fish-spear.

Gig'ging-ma-chine'. A machine for dressing woolen cloth by subjecting it to the action of teasels, whose fine hooks draw the loose fibers to the surface. A *napping-machine.*

The teasel is a kind of thistle (*Dipsacus fullonum*) cultivated for the purpose. The awns or bracts of the prickly head are furnished at the ends with little hooks, which are sufficiently strong to overcome slight impediments in drawing the loose ends of the filaments of wool to the surface. If the hooks of the teasel become engaged with knots which they cannot disentangle, they break, and it is this property which renders them so peculiarly suitable for this purpose. Artificial teasels, such as wire cards, have hitherto failed to answer the purpose as fully,

Digitized by Google

Fig. 2211.



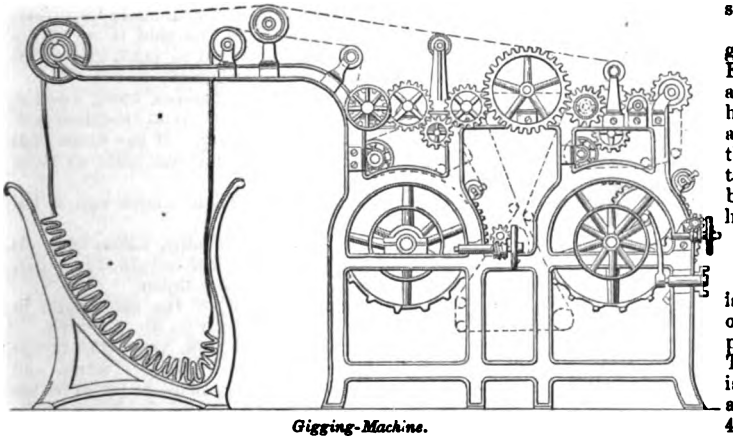
Gigging-Machine.

on account of their unyielding nature when they become engaged with a knot.

From 2,000 to 3,000 teasel-heads are arranged in frames attached to a hollow drum or cylinder, and the cloth, guided by rollers, is drawn in a direction contrary to that of the cylinder, the latter revolving somewhat rapidly and the cloth passing more slowly.

In the illustration, the ends of the cloth are sewed together so as to make it a continuous band which

Fig. 2212.



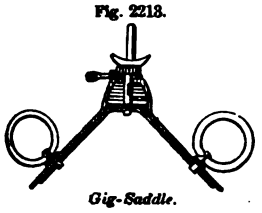
Gigging-Machine.

passes round again and again. See TEASELING-MACHINE.

In Fig. 2212 the cloth is teaseled in opposite directions on the same side without removal from the machine, and may be presented twice to each teaseling cylinder. It does not pass under the cylinders so as to catch the falling dirt, etc., and its napped surface is uppermost for inspection at all times.

Gig-ma-chine'. See GIGGING-MACHINE.

Fig. 2213.



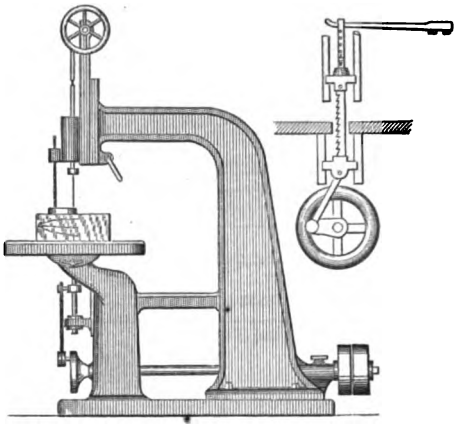
Gig-Saddle.

Gig-mill. A machine in which woolen cloth is napped or teaseled. A *gigging-machine.*

Gig-sad'dle. (*Saddlery.*) A small saddle used with carriage-harness, and carrying the *terrets* for the *driving-reins* and the *check-hook* for the *bearing-rein.*

Gig-saw. A thin saw to which a rapid vertical reciprocation is imparted, and which is adapted for

Fig. 2214.



Gig-Saws.

sawing scrolls, frets, etc. The motion is imparted by the crank and pitman, and the spring above *gigs back* the saw, keeping it strained on its upward stroke.

Scroll-saws are usually gig-saws or band-saws. In Fig. 2215, the saw-guides and operating mechanism have rotary adjustment around the point where the saw passes through the table so as to saw to a bevel. The motion of the hand-crank operates the worm *E*, which moves the segment *D* in the curved guides *C b*. The saw *H* is strained between the ends of levers *I I*, which are pivoted to the segment *D*. Thus the angle of the saw is capable of adjustment in a range of 90°; that is, 45° on each side of the perpendicular, while the other adjustments are the circular and vertical of the table beneath.

Gig-tree. The frame of a gig or harness saddle.

Gild'ing. The process of overlaying with gold.

Substances overlaid with fine gold-leaf are found in connection with the earliest Egyptian monuments, even as early as Osirtasen, 1706 B. C. In the time of Thothmes III., the era of the exodus, they had various modes of applying; in leaf, inlaying, or by beating it into other metals. Specimens may be seen in Dr. Abbott's collection, New York. We read that the wood of the ark was overlaid with gold, 1490 B. C.

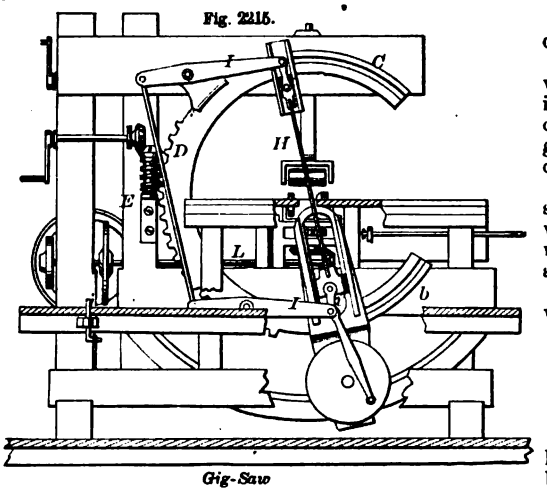
It was lavishly practiced in ancient Rome; parts of the Capitol were thus ornamented, a single ounce only making 450 leaves, each four inches square.

Gilding is performed:—

1. By laying on gold-leaf.

Digitized by Google

Fig. 2215.



Gig-Saw

2. By applying gold in amalgam, the mercury being subsequently evaporated.

3. By electro-plating.

4. By a sheet of metal soldered to the cheaper foundation metal.

5. By enameling.

A German plan cited in the "Philosophical Transactions for 1698" is described: —

Steep linen rags in a solution of gold, burn them; with a piece of cloth saturated in salt-water rub the ashes upon the silver. It is not durable.

The modes and purposes are various: —

Burnished gilding is destemper gilding polished by burnisher, and is used especially in picture-frames.

Chemical gilding is produced by galvanic action in the bath, or by affinity. See ELECTRO-PLATING; WASH-GILDING.

Cold gilding consists in rubbing the annealed metal with gilding-powder by means of a piece of cork dipped in salt-water. Polish with steel-burnisher.

Destemper gilding is applied to wood, plaster, or marble. Coat with size, followed by successive coats of finely powdered whiting, and face by rubbing with sand-paper between each coat. Coat with gold size, lay on the leaf, and polish with an agate or dog's tooth.

Electro-gilding. See ELECTRO-PLATING.

Friction gilding. See above, — *cold gilding.*

German gilding; a name for ELECTRO-PLATING (which see).

Immersion gilding; dipping the metallic article into a solution of pyrophosphate of soda in which terchloride of gold has been dissolved.

Or in a boiling-hot gilding-liquor of nitro-muriate of gold, water, and bicarbonate of potassa. (Elkington's patent.)

Or in a solution of gallic acid in water, ether, or alcohol, to which a solution of gold has been previously added. (Tabbot's patent.)

Japanners' gilding. Cover the surface with oil-size thinned with spirits of turpentine, and dab in gold in powder with a puff of wash-leather.

Leaf gilding; coat the paper or vellum with gum-water or glaire, lay on the leaf-gold and polish with an agate.

Mechanical gilding; any process in which the gold is made to adhere by glue, in contradistinction to chemical processes.

Mercurial gilding, by amalgam. See WASH-GILDING.

Oil gilding; coat with size; then repeatedly with calcined white lead or massicot ground in linseed-oil and turpentine; shave smooth the dried surface after each application; coat with gold size, then with the leaf; varnish; heat over a chafing-dish; varnish.

Varnish gilding, for carriages, etc. The same as above, except that the surface is varnished before receiving the gold, repeatedly varnished afterwards, and polished with tripoli and water.

Wash gilding; apply amalgam of gold and volatilize the mercury by heat.

Water gilding, same as *wash gilding.*

To state more in full: —

1. Gilding by gold-leaf is divided into, —

a. Burnish gilding.

b. Oil gilding.

a. In *burnish gilding*, the surface of the looking-glass or picture-frame stuff is prepared by *priming* of *white stuff*, laid on with a brush and followed by several thicknesses of the same material (hot size and whiting), but of a thicker consistence. This surface is smoothed and polished, then covered with several coats of a *size* made of pipe-clay, red chalk, black lead, suet, and bullock's blood, reduced by a solution of gelatine to the required thickness, to be laid on by a brush.

In gilding, the surface is wetted by a camel's-hair brush, the leaf is raised from the *cushion* by a tool called a *tip*, and laid upon the adhesive surface.

It is then burnished by a flint or agate burnisher, except in those parts where the gold is to have a *dead* or *frosted* appearance, called *matt*, and which are subsequently covered with size.

The tools of a gilder are a *cushion*, *knife*, and *tip*.

The *cushion* is flat, made of several thicknesses of cloth, and covered with leather. It has a marginal wall of parchment at one end and half-way along two sides.

The *knife* is pointed, straight-edged, and is not very sharp.

The *tip* is a layer of camel's hairs, whose but-ends are held between two cards which are glued together, forming a very light and elastic brush.

The gold-leaf is supplied by the gold-beater in books of 25 leaves, each measuring $3\frac{1}{2} \times 3$ inches.

A leaf being transferred from the book to the cushion is cut up by the knife into strips and pieces of the proper size and shape to lay upon the work, to which they are transferred by the *tip*. This tool being laid gently upon the leaf, the latter adheres slightly to the hairs, and is thereby raised and deposited in its place on the surface to be gilded.

b. Oil gilding differs from burnish gilding in the preparation of the surface, which is by coatings of *white stuff*, *clear cole* (a priming prepared with size instead of oil), and oil gold-size. The latter is a mixture of boiled linseed-oil and ochre, laid on by a brush.

The gold-leaf is laid on as in the former process, and is covered with a clear size.

Where parts are to be burnished, they are left for treatment by the *burnish* process just described.

2. An amalgam paste (see AMALGAM) is applied with a brush to metallic articles, which are prepared for its reception by aqua-fortis. Heat, carefully applied, drives off the quicksilver; the surface may be improved by burnishing. The name *water gilding* is also applied to this process. See WATER-GILDING.

3. A bath consisting of a chemical solution of

Digitized by Google

gold is prepared, and the object to be gilded is rendered electro-negative, and suspended in the liquid. A galvanic current being passed through the article suspended in the liquid, the gold becomes deposited upon it. Non-metallic articles may receive a coat of plumbago, to induce deposition thereon. A plate of gold is suspended in the liquid to feed the latter as it becomes impoverished. See ELECTRO-PLATING.

4. The form of gilding by soldering on a plate of the metal is seldom applied with gold, but is common with silver. A cheaper metal forms a basis or foundation to which is soldered a plate of gold. The two are then rolled down together, becoming gradually attenuated until they reach the required thickness, when they are worked together into the shape or object required.

Porcelain or glass is gilded by a magma of gold, quicksilver, gum-water, and borax. It is laid on with a hair-pencil, being thinned with turpentine and oil, like paint. It is black when used, but its natural tint is restored by burning in the enamel-kiln. The borax acts as a flux to unite the gold to the ceramic or vitric material. It comes dead-colored from the kiln, but is brightened by the burnisher.

1. (*Bookbinding.*) In gilding, the book is placed in the press between two boards, and the edges being cov-

Fig. 2216.

Bookbinders' Gilding-Tools

ered with *glaire* (albumen), a layer of gold-leaf is laid on and rubbed with an agate burnisher, fixing it to each leaf and at the same time giving it a polish.

In tooling, the portion of the cover is covered with glaire, the leaf laid thereon, and a heated tool carrying the desired ornament is pressed thereon. The tool may be a hand-stamp, as in the figure, or a roller or fillet having a periphery on which the pattern is repeated all round. The other appliances of the gilder are the cushion, knife, tip, etc.

Or: the surface is dusted with gum-mastic; the heated tool laid on the gold, which it catches up and transfers to the cover; pressure causes it to adhere.

Brass buttons are gilded by throwing them into a pan with a little amalgam of gold, and as much diluted aqua-fortis as will wet them all over; stir till they appear silvery, then wash, dry, and heat to volatilize the mercury.

Glass and porcelain are gilded by blending powdered gold with gum-water and borax to the biscuit, heating in a muffle, and polishing with a burnisher.

2. (*Photography.*) The treatment of the finished daguerreotype-plate with a salt of gold, generally sal d'or, — the hyposulphite of gold and soda, — which determines the deposition of finely divided gold upon the vaporous mercurial deposit of which the picture consists. By this means permanence is imparted to the picture.

Gild'ing-size. A viscid composition laid upon an object to hold a surface of gold-leaf. The bookbinder uses *glaire*, white of egg. The *oil-gilder* uses a mixture of linseed-oil and ochre.

Gill. 1. A *hackle*. A series of points which divide the ribbons of flax fiber into finer parallel filaments ready for drawing and spinning. A *porcupine*.

2. A timber vehicle consisting of a pair of wheels and a frame.

3. A measure of a fourth of a pint.

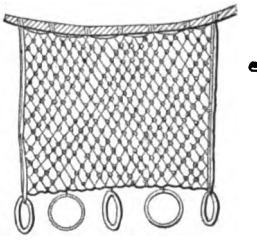
Gill-frame; Gill-head. A machine in which *stricks* of flax are drawn out into *slivers;* doubled and combined with other slivers, and redrawn until they assume the character of *rovings*, and are ready for the spinning operation. A *spreader*.

The name *gill-frame* (Fr. *aiguille*, needle) is derived from a number of vertical needles forming a comb, through which the *line* passes to the drawing-roller; the *gill* is attached to a *fuller-bar*, which rises and falls at intervals, and alternately detains and releases the *line*, which, by a series of operations, is converted from a *strick* to a *sliver* and then to a *roving*. See SPREADER.

Gill'ing-ma-chine'. A draw-head machine for flax. A GILL-FRAME (which see).

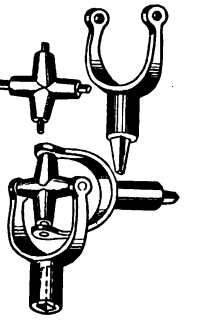
Gill-net. One suspended in a stream, having meshes which allow the heads of the fish to pass, and which catch in the gills to prevent the fish from detaching itself.

Fig. 2217.



Gill-Net.

Fig. 2218.



Gimbal-Joint.

Gim'bal-joint. A form of *universal* joint. (From *gemellus*, Latin, twin.) A two-part joint having articulations on axes at right angles to each other. Invented by Hooke. It is used as a shaft-coupling in the tumbling-rods of horse-powers, in drilling and sheep-shearing machines and elsewhere.

Gim'bal-ring. A single gimbal by which the cock-eye of the upper mill-stone is supported on the spindle to permit vibration. A *rynd*.

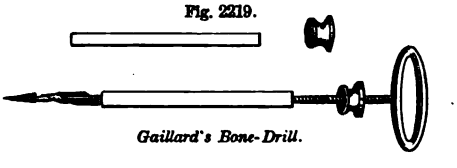
Gim'let. A small boring-tool. It has a leading screw, a grooved staff, and a cross handle.

Its invention is ascribed by Pliny to Dædalus, an artificer of Athens, about 1240. He considered it a point of honor to give an author in each case. In England it was formerly called a *wimble*.

The Grecian gimlet (*teretrion*) is frequently mentioned.

Gaillard's instrument for the insertion of steel pins in the treatment of fractures has four pieces, the handle, screw, sheath, and nut. The silver sheath is passed down to the bone, which is then bored by

Fig. 2219.



Gaillard's Bone-Drill.

the gimlet. The nut is then screwed down to draw the parts into apposition, and is left until bony adhesion takes place.

Gim'mal. A pair, or series, of interlocked rings. A *gimbal* (from *gemellus*, twin).

Gimp. (*Fabric.*) Silk twist interlaced with wire or a coarse cord. Used for trimming.

"My wife's black silk gown is now laced all over

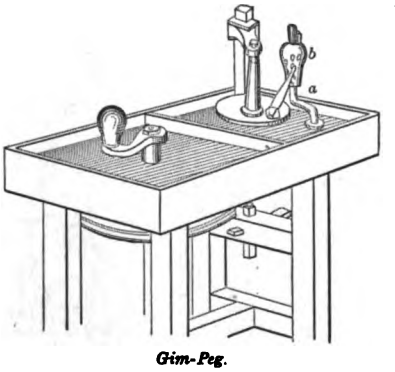
Digitized by Google

with black gimp lace, as the fashion is, in which she is very pretty." — PEPYS's *Diary*, 1661.

Gim-peg. A rest for the arm of a lapidary, consisting of a rod of iron bent into a cranked form *a*, and fitted with a flange that bears upon the surface of the bench.

It also serves as a holder for a block *b*, which is slipped thereon, and which serves as a guide for the vertical angle in cutting facets. The end of the stick is placed in one of the series of holes in the block, according to the angle required for the facet.

Fig. 2220



Gim-Peg.

The tang of the gim-peg is secured beneath the bench, and the block is secured by a wedge to the gim-peg.

Gimp-ma-chine'. A narrow-ware loom having devices at the edge of the warp to catch the woof and form loops or patterns, the gimp cords of various sizes being carried by independent shuttles or needles.

Gimp-nail. A small forged nail with a rounded head, used by upholsterers.

Gin. 1. A portable hoisting-machine *a* whose frame is a tripod, one leg being movable so as to vary its angle of elevation, and thus determine the hight of the apex; the other two legs preserve their relative distance, and form standards for the drum, around which the rope is wound by power applied to the hand-spikes. For heavy weights a fall and tackle is used; and for hoisting a bucket from a well or mine, simply a couple of pulleys to change the direction of motion of the rope. One pulley is suspended from the apex, and the other attached between the two permanent legs, so as to change the rope to a horizontal position, for the attachment of draft horse.

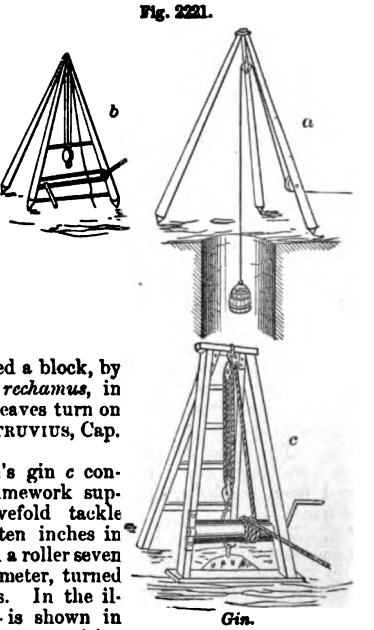
The gin *b* with fall and tackle is used for loading heavy objects, mounting ordnance, moving heavy castings in foundries. It is the most convenient form of portable hoisting-machine in places where traveling cranes and elevators cannot be had. The *shears* has two legs and the *derrick* one; the latter two require guys. See CRANE; DERRICK; WHIN; CAPSTAN; WINDLASS; WINCH; ELEVATOR.

In the United States military service gins are divided into three classes, — *field*, *garrison*, and *casemate*. Each is comprised of the same pieces, differing only in size and minor details of construction. The parts are the *legs*, the *prypole*, which is in fact the third leg, the *braces*, the *clevis*, and the *block* and *fall*.

A similar contrivance to the gin is mentioned by Vitruvius (about 40 B. C.): —

"Three pieces of timber are prepared, suitable to the weight to be raised, connected at the top by a pin, but spreading extensively at the feet; these are raised by means of ropes made fast to the top, and when raised are kept steady; to the top is fixed a block, by some called *rechamus*, in which two sheaves turn on axles." — VITRUVIUS, Cap. II., lib. 10.

Fig. 2221.



Gin.

Richardson's gin *c* consists of a framework supporting a fivefold tackle with blocks ten inches in diameter, and a roller seven inches in diameter, turned by iron levers. In the illustration, it is shown in its application to raising surface stone for removal out of the way of the plow.

2. A pump operated by windmill.

3. A coal-hoisting machine. See WHIN.

4. A snare for birds or animals.

5. A spirit distilled from grain and flavored with juniper berries.

6. A machine for separating cotton-fiber from the seeds.

Eli Whitney's cotton-gin, invented in 1793, revolutionized the culture and manufacture of the fiber by providing a mode of putting it into merchantable order at a reasonable price.

When done by hand, a man can clean but one pound per day. The *roller-gin* of India and China cleans from 40 to 65 pounds in a day. It has two rollers, which catch the fiber between them and carry it away, while the seed is detained by a comb.

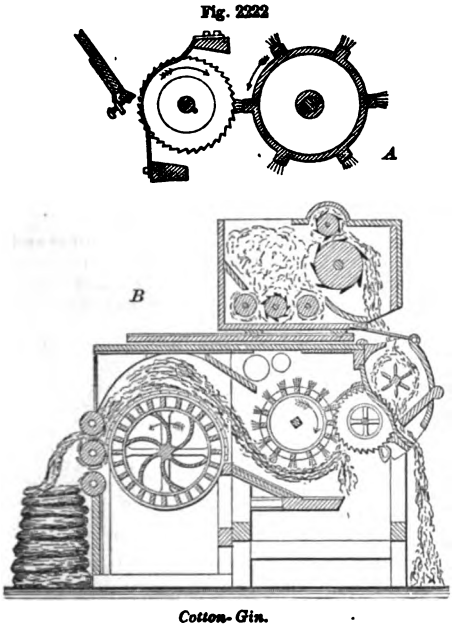
The combing instrument used in the Spanish colonies for removing the seed from the cotton-fiber is called *almarraes*. The syllable *al* indicates the Saracenic origin of the tool and its uses.

In Whitney's saw-gin (*A*) the cotton is placed in a long and narrow hopper, one side of which is formed by a grating of strong parallel wires ⅛ inch apart. Close to the hopper is a roller with circular saws 1½ inches apart. These, as they revolve, pass within the grating to a certain depth, and seize the fibers of cotton, dragging them between the wires which detain the seeds. The cotton is swept from the saws by a revolving cylindrical brush.

In the lower view (*B*) is a more modern form of the same invention. The feeding-chamber is mounted above the gin, serving the double purpose of picking open and thoroughly separating all lumps and matted seed-cotton, and feeding it steadily and uniformly the whole width of the gin in small pellets or masses to the chamber below, in which is a roll-supporter, which presents the cotton regularly to the saws, and is itself driven by the action of the saws upon the under side of the roll. The brush cylinder removes the lint from the saws and delivers it into a chamber, which has for its bottom a revolving gauze cylinder, through which the air escapes while

Digitized by Google

Fig. 2222

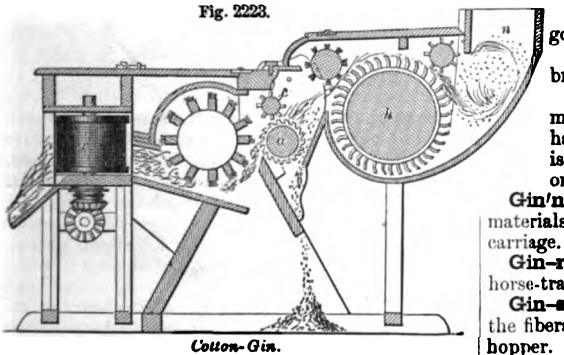


Cotton-Gin.

the lint is arrested and gathers upon the surface of the cylinder in a continuous bat, and is discharged by doffing-rollers ready for the press.

Fig. 2223 shows a form in which the cotton is taken by a toothed feeding-cylinder *h* from the hopper *n*, a stripper keeping superfluous cotton in the hopper; a brush-cylinder delivers the cotton from the feeding-cylinder *h* to the ginning-cylinder *a*. *c* is the brush-cylinder, and *v* one of a pair of wire-cloth covered condensing rolls, which press the cotton into a sliver and at the same time conduct away the dust and motes.

Fig. 2223.



Cotton-Gin.

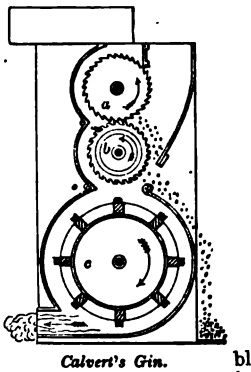
Other gins operate by means of rollers and knives and pinching devices which grasp the lint and tear it from the seeds, as in the roller-gin of India, already mentioned. In one case, as the combs alternately move up and down, they act upon the cotton, which is drawn in by the continuously revolving rolls, and comb back the seeds by working against the upper and lower edges of the bar.

In another, the fiber is grasped by positive devices close by the seed, and is so held while another part pushes the seed away from the fiber. The holders work intermittingly, or two sets alternately, one set holding the fiber or drawing it away, while the other set pushes the seeds away.

Another has a roller-knife acting in combination with a gin-roller, and *doctor* or pressing-knife, the roller-knife having fixed thereon a series of circular plates or disks, the edges of which come nearly in contact with the edge of the doctor or pressing-knife, and also with the surface of the gin-roller, in such a manner as to cause the seed and refuse to be beaten off, and at the same time to cause the fibers and seeds to be moved to and fro along the edge of the doctor.

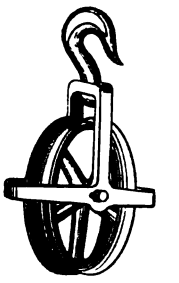
Calvert's toothed-roller gin has a guard-toothed roller *b*, which acts in conjunction with a guard-roller *a* to remove the lint from the hopper and keep back the seeds. The brush-roller *c* removes the lint from the roller *b* and conducts it to the exit.

Fig. 2224.



Calvert's Gin.

Fig. 2225.



Gin-Block.

Gin-block. A tackle-block with a hook to swing from the gib of a crane or from the sheer of a gin.

Gin'gal. An East Indian breech-loading fire-arm carrying a ball of from four to eight ounces. See JINGAL.

Ging'ham. (*Fabric.*) A linen or cotton goods, colored in the thread.

Ging'ing. The lining of a shaft with bricks or masonry.

Gin'gly-mus. An elbow-joint which permits no other motion than in one plane, having no rolling articulation. Such a joint is the ordinary two-leaved hinge which moves on a pintle; such are also most *toggle* joints.

Gin'ny-car'riage. A railway car for conveying materials; probably English provincial for engine-carriage.

Gin-race. (*Mining.*) A miner's term for the horse-track of a whin or hoisting apparatus.

Gin-saw. One used in a cotton-gin for drawing the fibers through the grid, leaving the seed in the hopper. See GIN.

Gin-wheel. 1. A wheel in a cotton-gin. It may mean a wheel with curved pointed teeth or claws, which act as the teeth of the usual saws in drawing the fiber through the grid; or the brush-wheel, which cleans the lint from the said wheel or saw. See GIN.

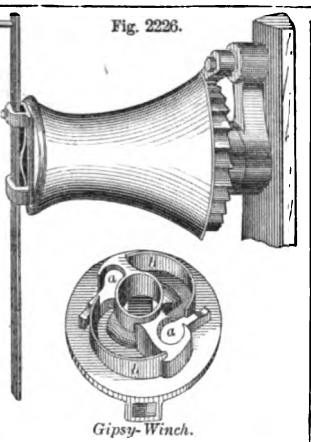
2. The wheel or drum of a whin.

Gip'sy-winch. A small winch having a drum, ratchet, and pawl, and attachable to a post. The handle of the winch is attached by stirrups to a cap revolving on the axis. This cap is provided with a pair of pawls *a*, which, by means of springs *b*, are forced against ratchet teeth in the interior of the small end of the barrel. By this means two motions can be applied to the winch, the ordinary rotary method

Digitized by Google

of working the handle, and a reciprocating motion in which the handle is worked up and down like a pump-handle. In the ordinary rotary motion the ratchet movement of the cap is not utilized; but, when the maximum power of the apparatus is required, the pumping motion is adopted. The handle is extensible according to the power required, and about ten times the usual power may be obtained by the reciprocating motion, owing to the leverage obtained and the favorable position for the workman to throw his weight upon the handle, as in working a windlass. See also BRACKET-CRAB.

Fig. 2226.



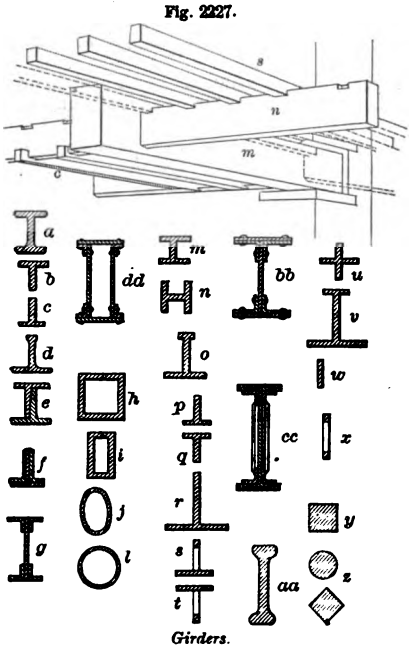
Gipsy-Winch.

Gir'an-dole. A branching candle-holder or chandelier. A *gasalier*.

Gird'er. A principal beam of a floor, spanning the distance from wall to wall, and affording a place of attachment for the *binders*, to which the floor and ceiling joists are connected.

In roofs of a less compound structure, the girder or summer-beam, sometimes trussed, spans the building longitudinally, and the joists proceed from it to the walls on each side. See FLOOR.

Fig. 2227.



Girders.

Girders are often compound, the timbers being scarfed together and stayed by truss-work or fished at the junction.

Smeaton bent the girders upward and trussed them in that position.

In double-framed floors, the *binding-joists* *n*, instead of resting on the walls, are supported by large timbers *m*, called *girders*. The *bridging-joists* *s* rest on the binding-joists *n*, and the *ceiling-joists* *c* are secured beneath the girder *m*.

a to *l* are forms of wrought-iron girders.

m to *z* are forms of cast-iron girders.

Plate-iron girders are made of several forms.

The *I-girder* *a a* is rolled in one piece.

The *compound I-girder* *b b* has flat top and bottom plates secured by *angle-irons* to the *web*.

Another form of *compound-beam* *c c* has upper and lower members built of several layers of plates riveted to each other, and to a pair of angle-irons whose other arms are riveted to the web, which is strengthened by vertical T-irons.

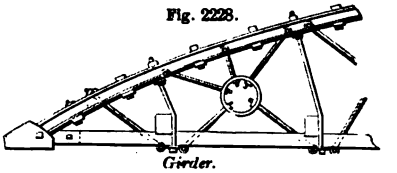
The British rule for wooden floor girders is as follows: —

Length of Bearing. Feet.	Depth. Inches.	Width. Inches.
10	9	7
12	10	8
14	11	9
16	12	10
18	12	11
20	13	11
22	14	12
24	15	12
26	16	12
28	16	13
30	16	14

The *box-girder* or *box-beam* *d d* has a double vertical web. It is stated by Rankine to have been long employed in the platforms of blast-furnaces, and to have been first used in railway bridges by Thomson, on the Pollok and Gowan Railway, in 1832.

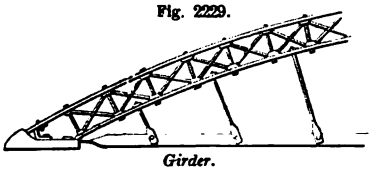
Figs. 2228 and 2229 are forms of arched girders for bridges. The former has for an arc a flanged iron beam and tension trussing in panels. The arch of the latter is formed of upper and lower concentric iron arcs connected by diagonal and radial braces. The chord is connected to the arch by radial rods.

Fig. 2228.



Girder.

Fig. 2229.



Girder.

The ends of the arch and chord are secured in the metallic shoe. See also LATTICE-GIRDER; HALF-LATTICE GIRDER; BOWSTRING GIRDER; LATTICE; TRUSS; ARCHED BEAM, etc.

The Girard Avenue Bridge over the Schuylkill, at Philadelphia, has five spans of wrought-iron lattice girders, and is illustrated under IRON BRIDGE. Under the same title are also shown a number of cast-iron and wrought-iron bridges.

See also PIVOT-BRIDGE, where are girder-trusses resting at midlength on piers. See also STEEL TUBULAR-BRIDGE; TUBULAR-BRIDGE.

See also IRON, ANGLE, where a large number of forms of angle-iron are shown.

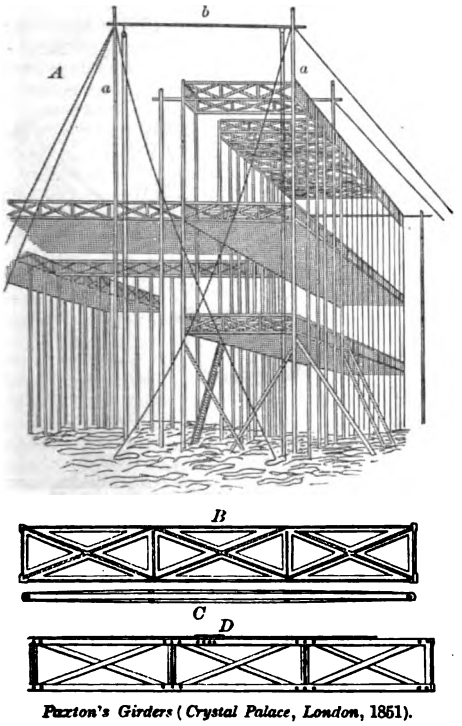
Fig. 2230 *A* represents a portion of the framing of the London Crystal Palace of 1851, showing the means adopted for getting it into position. This was effected by means of upright poles *a a* connected by a cross-piece *b*, and steadied by guys. The supporting columns were, by means of tackles attached to the cross-piece, hoisted into vertical position and there bolted, after which the girders were hoisted up in a similar way and secured to the columns.

B is an elevation, and *C* a plan of one of the cast-iron girders. They were 23 feet 3¼ inches long, and

Fig 2230.



Paxton's Girders (Crystal Palace, London, 1851).

3 feet deep, and connected at top and bottom to the columns. Their great comparative depth enabled the latter to resist great lateral thrust, and imparted extreme stiffness to the structure, with the least possible weight.

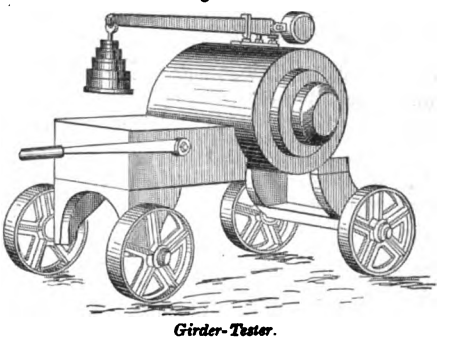
D is a form of wooden truss employed in the same structure.

Gird'er-bridge. A bridge supported by beams resting upon abutments at the ends. The beam is usually compound. A *truss-bridge*.

Gird'er-test'er. A form of hydrostatic press for testing the strength of girders. The form shown is on wheels, and has a safety-valve. By bolting two girders together, and placing this machine between them, they may both be tested at one time.

Gir'dle. (*Diamond-cutting.*) The point of greatest marginal circumference of a *brilliant-cut* diamond, at which it is grasped by the *setting*. The projecting portion, rising about the *setting*, is the *bizet*, and has one third of the depth of the stone. It has thirty-two facets, and terminates in a flat face called the *table*. The imbedded portion of the stone has two thirds of the depth of the gem, and is called the *culasse*; it has twenty-four facets and terminates in a flat face, the *collet* or *culet*. See BRILLIANT.

Fig. 2231.



Girder-Tester.

Girt. A small girder. Used in roofs or bridge-frames.

A *girth*.

Girth. A band passing around the body. A *surcingle*.

More specifically: a band passing beneath the belly of a horse and buckled at each end to a girth strap of the saddle.

Girt-line. (*Nautical.*) A whip-purchase, depending from a lower-mast head and used in hoisting rigging and gear of the mast.

Gis-arm. A weapon formerly used. It had a long handle, a curved blade, and a prong projecting from the back of the blade.

Git. (*Founding.*) The entrance for molten metal into a mold. A *gate*.

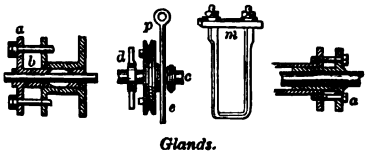
Gla'cis. (*Fortification.*) The superior slope of the parapet of the *covered-way*, forming a gentle slope towards the *country*, and protecting the *revetment* of the *scarp* from an enemy's fire. See BASTION.

Glad'stone. A four-wheeled, two-seated pleasure-carriage, with a driver's seat and dickey.

Glaire. (*Bookbinding.*) White of eggs. Used as a size in gilding.

Gland. 1. The cover of a stuffing-box. The cylindrical sleeve *b* presses upon the packing around

Fig. 2232.



Glands.

the piston-rod to make a steam or air-tight joint. The exterior flange *a* is perforated for the passage of the bolts by which the gland is tightened.

2. The common clutch consists of a loose pulley *p* which is slipped upon the shaft *c* by means of the lever *e*, so that the studs on the pulley engage with the *gland d*, which is fast to the shaft. This causes the motion of the pulley to be imparted to the gland and shaft. The contrary motion of the lever disconnects the power from the shaft.

3. (*Founding.*) A hooked bar by which the parts of a molder's flask are clamped together.

4. A plate *m* through which the ends of a band or tightening clevis pass. A clip-plate.

Glass. 1. Glass is a compound substance formed by fusing together mixtures of the silicates of potash, soda, lime, magnesia, alumina, and lead. The proportions vary in the different kinds of glass.

Silica fused with alkalies yields a transparent

Digitized by Google

glass; if the proportions of alkali and silica be as three to one, the compound is soluble in boiling water, and is called *soluble glass*, *water-glass*, or soluble silica. The greater the proportion of silica the less fusible is the compound.

Silica fused with lime, magnesia, baryta, or alumina yields an insoluble porcelainous compound, fusible only at a high heat.

Glass is divided into —

Flint-glass; used in making table ware and many articles of domestic furniture and fittings. The molten glass is taken from the pot by a *ponty*, and is blown or pressed into shape, or, by a combination of operations, is held in a mold while being blown.

Crown-glass is taken by the ponty from the pot, and is then blown and whirled till it becomes globular. A ponty tipped with molten glass is applied to the bulb, the blowing-tube detached, leaving a hole. The globe being again whirled, the glass flashes into a circular disk adhering by a boss in its center to the ponty. See CROWN-GLASS.

Sheet-glass. The glass withdrawn by the ponty from the pot is blown and whirled till it assumes a cylindrical form. The ends being cut off and the cylinder slit longitudinally, the sheet is heated, pressed, and rubbed until it is flattened out. This is also called *cylinder-glass; broad-glass* (which see).

Plate-glass is made by pouring it upon a table which has a marginal ledge of a hight equal to that designed for the thickness of the glass. A roller travels over the table, resting on the ledges and flattening out the glass, which is thus made of equal thickness throughout. See PLATE-GLASS.

Bottle-glass has nothing peculiar in the mode of its manufacture, but is made of coarse ingredients.

The proportions of materials in different kinds of glass vary with different places, as many notable proportions are, as it were, accidental; that is, are present in the sand which is most readily accessible, or are used to correct such faulty admixture. The following analyses are approximate: —

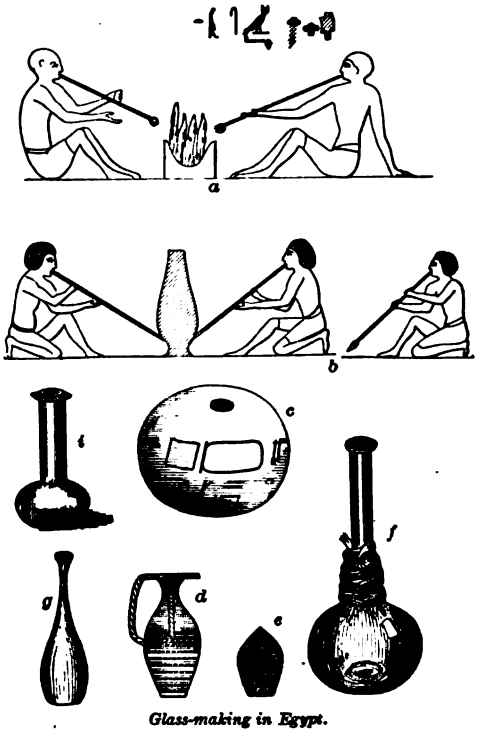
	Plate.	Broad.	Crown.	Flint.	Bottle.	Tube.	Optical.
Silica	78	69	63	52	59	78	43
Potash	2		22	14	2	12	12
Soda	13	16			10	8	
Lime	5	13	12		20	11	
Alumina	2		3	1	2	1	1
Oxide of lead				32			44
Oxide of iron		2		1	7		
	100	100	100	100	100	100	100

Glass was known in Egypt in the reign of Osirtasen, 1740 B. C. He may have reigned about thirty-four years when Joseph came to Egypt. In the tombs of Beni-Hassan of this date, the glass-blowers are shown at work (*a*), each with a bulb of glass on the end of his blow-pipe, into which he is blowing, while he keeps his glass hot by exposure to the fire. The same operation is depicted in other Egyptian tombs of various epochs. The glass at the end of the blow-pipe is colored green in the original painting.

Another representation (*b*) of the same process is shown in a tomb at Thebes, where one workman labors at the bulb of glass in the earlier stage of its formation, and two unite to inflate the bottle when it has acquired some size. In figure *i* is shown a glass bottle found in Thebes. The bottle came to represent wine in the hieroglyphics.

c shows a glass bead belonging to Captain Henvey, and the hieroglyphics contain the name of a monarch who lived 1500 B. C. The Egyptians attained an excellence in the manufacture of counterfeit amethysts and other precious stones which has not been excelled, and Winckelmann considers their skill in all departments of vitreous art to be in advance

Fig. 2233.



Glass-making in Egypt.

of any succeeding age. They made glass of various colors, imitation pearls, and two films of glass were made to inclose gold plates.

Athenæus states that the glass of Egypt was famous. Strabo says that one very perfect kind could only be made in Egypt.

Herodotus speaks of rings of melted stone (no doubt, glass) as decorating the ears of the sacred Egyptian crocodiles.

The manufactures of glass among the Egyptians were of bottles, vases, and other utensils, probably lamps; wine was brought to table in glass bottles, handed to guests in glass cups, and bodies were sometimes buried in glass coffins. They also made glass beads, charms, amulets, and images.

The inscriptions on the Egyptian articles of glass were probably cut by diamonds or the dust of diamonds or other hard gems. The Israelites learned the art from them, and from the skill thus obtained were enabled to engrave the stones in the breast-plate of the high-priest.

Some glass bottles among the Egyptians were inclosed by wicker-work like the *damagán* of Khorassan, a city of Persia, once famous for its glass-works. (Hence our *demijohn.*)

Others were covered with rushes like the Florentine flask. Others were partially covered with leather.

d is a bottle with a partial leathern cover.

e is a glass damagán.

f is a glass bottle encased in papyrus.

Remains of painted glass have been discovered in the ruins of Assyrian, Egyptian, Greek, Roman, and Etruscan cities.

In the magnificent collection, happily housed in New York, discovered and disinterred by General di Cesnola at Golgoi and Idalium, island of Cyprus, are nearly 2,000 specimens of Greek and Phœnician glass. The effect of decay or some rearrangement of the particles during the thousands of years of burial has rendered these articles dazzlingly iridescent.

"The boundless array of objects, reflecting from broad or curved surfaces tints positively outside of all experience, confuse the most accurate observation. Broad dishes, marbled with hues like those of incandescence; pots and jars and bottles, now plated over with strong surface-color like a coat of burnished metal, now sending light, pearly hints of variegated radiance, from elusive depths; or cups fantastically pied with scales of iridescence over their own strong original colorations, are scattered around a considerable apartment, defeating all sense of strict estimation, and cheating the mind with the notion of a possible perfection in the manufacture only compatible, as it seems, with decay. Some of the platters look as if Turner had painted skies on them in his maddest mood, and had been allowed to use flames for colors. The general effect seems to suggest that all the sunsets that have glimmered over Cyprus since these crystals were lost in the earth had sunk into their hiding-place and permeated their substance." — *N. Y. Nation.*

Most of the pieces are of simple inflated shapes, but some are pressed, having monograms and inscriptions in relief, opaque glass in mingled colors, sticks of twisted colors.

Small glass bottles from the Phœnician tombs, beneath the level of the Greek necropolis, show a reddish color when transmitting sunshine.

It would be tedious to enumerate the articles of glass found by Dr. Abbott in the tombs of Egypt. The myth related by Pliny and so widely copied in relation to the invention of glass-making by certain Phœnician mariners, has been exploded by researches in the land of the Nile. A few pieces in the collection may be noticed: —

Two beads of blue *glass* attached to a gold necklace stamped with the name of Menes, the first Pharaoh of Egypt (over 2000 B. C.).

A cylindrical ring of blue glass.

Glass bottles from Sakkarah, Gizeh, etc.

Glass beads, — white, blue, red, green, and black.

Variegated glass ornaments.

Semi-translucent glass imitations of alabaster.

Opaque red and blue glasses.

Tazzas and images of green, blue, and other colors.

Beads of colored glasses in layers.

Ornaments of mosaic glass.

A glass model of the crown of Upper and Lower Egypt.

Grotesque faces and portraits in glass.

Glass imitations of precious stones.

Glass rings of various colors.

Glass artificial eyes.

Glass spoons, shaped and colored in imitation of shells.

Layard, in his interesting work on Nineveh, says: "I was rewarded by the discovery of two small vases, one in alabaster and the other in glass, both in the most perfect preservation, of elegant shape and admirable workmanship." Each bore the name and title of the Khorsabad king, written in two different ways, as in the inscriptions of Khorsabad. The cuneiform inscription on one small green glass vase was to "Sargon," king of Assyria, the founder of Khorsabad, about 709 B. C. He also found a plano-convex glass lens 1½ inches in diameter and $\frac{3}{10}$ of an inch thick.

The lachrymatories (*g*) of ancient Phœnicia were of glass or pottery, and are found in great numbers on opening the tombs and sarcophagi of that land. Thompson records the opening of an ancient tomb in a garden of the city of Beirut, which contained scores of these tear-bottles in thin glass or unglazed pottery. They have a slender neck, a broad bottom, and a funnel-shaped top. David says: "Put thou my tears into thy bottle."— Psalm lvi. 8. These bottles are probably coëval with the sweet singer of Israel.

A record of the Phœnician trade on the western coast of Africa is still preserved in the peculiar glass beads found there.

The pillar of emerald seen by Herodotus in the temple of Hercules at Tyre (Book II. 44) was probably of glass. "Of all stones," says Pliny, "the emerald is most easily imitated" (XXVII. 12).

The Tyrians erected the first glass-houses mentioned in history, and practiced the manufacture for many ages before other contemporary nations attempted it. From Syria the art was brought by the Crusaders to Europe (1177), and established in Venice, which long had a monopoly therein and attained great excellence. See p. 976.

Theophrastus, the pupil and successor of Aristotle, notices the fitness of the sand at the mouth of the river Belus for the manufacture of glass.

Lucretius termed it *vitrum*.

Cicero mentions glass, linen, and paper as the common articles of Egyptian merchandise.

Scaurus, 58 B. C., introduced it in the scena of his gorgeous theatre, which was divided into three tiers: the lower of marble, the middle of glass, the upper of gilded wood.

The price of a glass drinking-cup in the time of Strabo was half an *as*. The *as* was about one cent.

The Museo Borbonico of Naples contains about 2,400 specimens of ancient glass, recovered principally from Pompeii and Herculaneum. They represent numerous forms of glass ornamentation in green, opal, blue, red, white, and yellow.

The Barberini vase, now known as the "Portland vase," was discovered about 300 years since, a short distance from Rome, in the tomb of Alexander Severus, who was killed by Maximinus, A. D. 235. The body of the vase consists of dark blue glass, on the surface of which are delineated in relief elaborately wrought figures of opaque white enamel. So admirably is it made that it was long supposed to be a genuine sardonyx.

Fictitious gems in glass were known in Rome, as were also mosaic glass, glass plates for paving, wall-lining, windows.

Lucretius (95 – 51 B. C.) accounted as follows for the fact that sound would pass through some objects while images would not: —

"The voice can pass unbroken through winding pores of bodies, *though* images refuse *to pass through them;* for the *latter* are broken to pieces unless they go through straight passages, such as those of glass, through which every image flies." (Book IV. 613-619.)

Opalescent glass is referred to by the Emperor Hadrian in a letter to the consul Servianus, thanking him for a present of three curious cups of glass which "reflected like a pigeon's neck a variety of colors."

Flexible glass is referred to by Pliny, Petronius, Dion Cassius, and others who copied from them.

Digitized by Google

The two former refer to vases made in the time of Tiberius. It is not fully credited.

Julius Cæsar found the Britons in possession of glass beads, which they probably obtained of the Phœnicians in return for tin. Rome had few glass windows till the reign of Nero. Some are found in the ruins of Pompeii, buried 79 B. C.

Pliny describes the mode of making glass, and states that Sidon was *formerly* famous for its glass-houses, and that its people first invented mirrors. In this day, says he (A. D. 79), throughout the Spanish and Gallic provinces, glass is made of white sand and niter by a double fusion. He also speaks of flexible glass, stating that "he hardly believed the story," which was a wonderful thing after telling such a farrago of stuff about medicines and magic. In his day — he says — glass had quite (? nearly) superseded the use of silver and gold for drinking-vessels.

He noticed the effect of lenses, stating that "globular, glass vessels, filled with water, when brought in contact with the rays of the sun, become heated to such a degree as to cause articles of clothing to ignite." He omitted to notice that the glass remained cool, and only transmitted and concentrated heat.

Previous to the introduction of glass into Europe in quantities to make it available for ordinary household use, a mineral substitute was employed.

Crystals of gypsum are generally in the form of more or less compressed rhomboids, which are easily divisible into thin laminæ by splitting them parallel to their two broad planes. Such laminæ were employed at Rome in the reign of Tiberius for many of the purposes for which we at present use glass. Spain and Cappadocia furnished the best, sometimes of the length of five feet. This variety of gypsum was known by the name of Lapis Specularis, from the use to which it was applied, namely, in glazing windows and conservatories in which were placed fruit-trees, to protect their produce from the winter's cold, and in the construction of beehives, as Pliny expressly informs us, for the purpose of enabling the curious to observe the proceedings of these interesting insects. The temple of Fortune at Prœneste was built of slabs of gypsum, through which the light came and fell on the statue of the goddess, which was placed in the center of the edifice. The *specular stone* of the ancients often signifies *mica*.

Glass panes for windows are mentioned in the writings of Gregory of Tours, who flourished in the last quarter of the sixth century. He stated that churches were furnished with windows of colored glass in the fourth century of our era.

Jerome, A. D. 422, states that glass was melted and cast into plates for windows. In the sixth century Paulus Silentarius notices that the windows of the Church of St. Sophia at Constantinople were glazed.

The oldest glass windows now in existence are of the twelfth century, and are in the church of St. Denis, France.

In the thirteenth century, the Venetians exceeded all others in glass-making.

Æneas Sylvius states that, in 1458, the houses in Vienna had glass windows. He regarded it as a sign of opulence.

In France, church windows were generally glazed in the sixteenth century, though there were but few glass windows in private dwellings.

Talc, isinglass, horn, oiled paper, and thinly shaved leather were generally used instead of glass throughout the civilized world.

Blue glass, colored by the addition of cobalt to the frit, was discovered about 1550 by Christopher Schurer of Platten, Bohemia.

Glass was imported into England, A. D. 1177; the manufacture was established in that country, 1557. In Savoy, the same year.

Plate-glass was made at Lambeth by Venetian artists, 1673.

The British Plate-Glass Company was established 1773.

An active manufactory of glass exists at Hebron, in the land of Palestine, — the same Hebron where is the cave of Machpelah, bought by Abraham for a sum of money of Ephron, one of the sons of Heth. The tombs are preserved in rigid seclusion from Jew and Christian; of the latter, not one lives in the town of 5,000 people. Dr. Thomson gives an account of it in his work, "The Land and the Book," but could not reach the vault.

The manufacture consists of party-colored glass bracelets for the Jerusalem market, and lamps for Syria, Palestine, and Egypt. The solid articles are formed from a bulb of glass adhering to the end of an iron, being shaped by the aid of a long knife. The glass is twisted, pressed into an approximate shape, then reheated and stretched by another rod.

The Crystal Palace of London was built in 1851, after the designs of Sir Joseph Paxton, soon after the abolition of the excise duty on glass, and was considered to celebrate that event in a worthy and effective manner. The roof and sides were, to a great extent, of glass, the sash being of wood, and the frame of the building a combination of wrought and cast iron. The following are some of the data and dimensions: —

Length	1,848 feet.
Width	408 feet.
Area roofed in	772,784 square feet.
Floor area of galleries	217,100 square feet.
Sash-bars	200 miles.
Glass	896,000 square feet.
Wrought-iron	448,000 pounds.
Cast-iron	8,512,000 pounds.
Visitors	6,039,195 persons.
Receipts	£506,100
Expenses	£292,794
Value of exhibited articles	£2,000,000
Number of exhibitors, —	
British	7,381
Foreign	6,556
	13,957

In 1838, Mr. Robert Lucas Chance, of Birmingham, England, successfully introduced the manufacture of Bohemian sheet-glass into his district. Mr. James Chance perfected the process of grinding and polishing sheet-glass, now known as *patent plate*.

"The 'London Builder' gives, as derived from an eminent member of this firm, the following record of improvements in the glass trade, during the last fifty years: —

"1. The substitution, about the year 1830, of carbonate of soda as the alkaline ingredient in glass in the place of kelp, and subsequently, for crown and sheet glass, of sulphate of soda in the place of carbonate.

"2. An increase in the size and improvement in the workmanship of the plates, sheets, and tables produced.

"3. An improvement in the color of the glass by the use of purer materials and modifications in the process of melting.

"4. Numerous improvements in the flattening

Digitized by Google

of sheet-glass, resulting in the removal or diminution of many imperfections.

"5. The use of the diamond in the process of splitting cylinders in the place of a red-hot iron.

"6. An increase in the size of the melting-pots and furnaces, with the view of economizing coal and labor.

"7. The adoption, in the casting of plate-glass, of various mechanical contrivances. The origin of some important improvements of this class is due to the present manager of the Birmingham Plate-Glass Company.

"8. The use of the same pot for the two processes of melting and casting plate-glass, superseding the old method of transferring the contents of the melting-pot into the vessel used for casting.

"9. The substitution of small coal or slack in the melting processes in the place of the large coal or lumps.

"10. The application of Siemen's regenerative process to the melting of glass, by which the amount of smoke is greatly diminished, the color of the glass is improved, a greater control is obtained over the furnace, and a saving of fuel is effected wherever, by this process, slack can be substituted for large coal or lumps. These advantages are to some extent counterbalanced by the increased cost of the furnace, and its increased liability to get out of order. The process, however, as applied to glass-making, is so new that there has been scarcely time as yet to overcome the difficulties which have presented themselves.

"Messrs. Chance are widely known for the production of dioptric apparatus for lighthouse illumination. Mr. Alan Stevenson remarks: 'Nothing can be more beautiful than an entire apparatus for a fixed light of the first order. It consists of a central belt of refractors forming a hollow cylinder six feet in diameter and thirty inches high; below it are six triangular rings of glass ranged in a cylindrical form, and above, a crown of thirteen rings of glass, forming by their union a hollow cage, composed of polished glass ten feet high and six feet in diameter. I know of no work of art more beautiful or creditable to the boldness, ardor, intelligence, and zeal of the artist.' More than one hundred and fifty of these dioptric lights have already been produced by Messrs. Chance, for almost all parts of the world."

A vitreous, opaque material, called from its translucent, milky appearance, "hot-cast porcelain," is now made in Philadelphia. It is understood to be made from cryolite or feldspar, whose natural and added fluxes render them fusible at a comparatively moderate temperature, yielding a mass viscid and tractable while hot, lustrous and strong when cold.

It was proposed to make the headstones for the graves of Union soldiers of this material. One side of the mold would have a tablet in which the letters of the inscription would be set up. It would seem to be impossible to find an equally good material for the purpose. Glass (ordinary), marble, or enameled iron are inferior and more frangible.

Plates of ice are used instead of panes of glass in the Siberian *yurts*, or winter-quarters, which are partly subterranean.

(*Optical Glass.*) Crown and flint glass are combined in the construction of achromatic lenses. The former of these is a compound of silex, potash, and lime; the latter contains in addition oxide of lead. This tends to sink to the bottom of the melting-pot, rendering the glass of unequal texture and consequent refracting power. In this consisted the principal difficulty in obtaining object-glasses of large size. So late as 1830, the largest object-glasses of satisfactory performance which were produced did not exceed five or six inches in diameter. Previous to this, however, Guinand, a melter in a glass-manufactory at Soleure, in Switzerland, succeeded in making large disks, but he kept his process secret, and died without disclosing it, though it continued to be practiced by his son and afterward by M. Pfeil of Paris, who exhibited at the Exposition of 1867 a disk of the diameter of 72 centimeters, — over 28 inches. The process of making these disks consists substantially in uniting numerous small selected masses of uniform density and refracting power into one large mass by pressure while in a plastic state. In 1855, Messrs. Chance of Birmingham exhibited at the Exposition of that year a pair of disks, crown and flint, about an inch larger than those of M. Pfeil. See LENS.

2. (*Nautical parlance.*) *a.* A telescope.

b. The barometer.

c. The half-hour or sand-glass which regulates the watches.

d. The half-minute or quarter-minute sand-glass used with the ship's log.

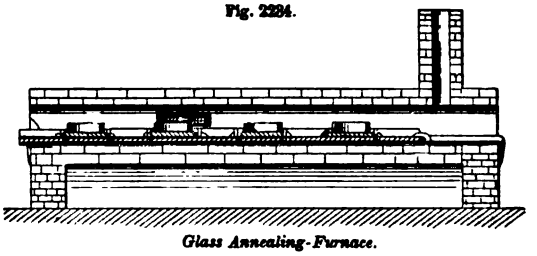
Glass An-neal'ing-fur'nace. One in which articles or sheets of glass are kept for a while in a heated condition, and allowed gradually to cool. A *leer*. (See ANNEALING.) In the illustration, which is a *leer* for glass jars, the trays of ware are put into the arch at one end and pushed in succession to the discharge-end. The heat of a furnace is thrown into the *leer* at a point between feed and discharge ends, so that the heat is graduated both ways.

Glass-blow'ers' Lamp. A gas or alcohol lamp. See BLOW-PIPE.

Fig. 2234.



Glass Annealing-Furnace.

Glass-blow'ing. A mode of manufacturing glass-ware and window-glass by taking a mass of viscid glass from the melting-pot on the end of the blowing-tube, and then inflating the mass by blowing through the tube, rolling on the *marver*, and exposing it at the furnace opening where its contained air is expanded and itself enlarged. Glass-blowing enters into most of the operations with glass, but the process is modified to suit varying circumstances. See CROWN-GLASS; CYLINDER-GLASS; FLINT-GLASS, etc.

Glass-blowing is also used in connection with molds, which give the exterior form to the article, and in the ingenious operations of making glass articles and toys under the BLOW-PIPE (which see).

The art of glass-blowing long reigned supreme at Murano, one of the islands of the maritime city Venice. After some preliminary matters, an observer states: —

"At the present moment you may set before Antonio Seguso or Antonio and Giovanni Barovier, of Murano, any specimen of old Venetian glass, and they will copy it with all its perfections, and, if you choose, its imperfections, and hand you a fac-simile in color, form, and *weight*, made under your own eye. On my first visit, the head workman was requested by Salviati to make me any article I might fancy. I chose a wineglass with deep bowl, initial stem, and broad, ruby-tinted foot. The man dipped his hollow iron rod into a pot of molten white glass, caught up a lump, rolled it on an iron slab, popped it into the furnace, blew through his rod, tossed it aloft, and a hollow ball appeared. His assistant handed him a rod of metal, in which a green serpent seemed coiled in a white cage; this he caught, and, quick as lightning, formed two initials, touching the bowl with the tip of the M, to which it adhered, Then his assistant offered more white glass, which was joined to the bottom of the M, spun round, opened with the nippers, and so the foot was formed. Again into the furnace, and then the shears opened and hollowed the deep and slender bowl. Then the assistant handed a scrap of ruby molten glass, of which the master caught a hair, as it were, wound it round the rim of the bowl and of the foot. Once more into an upper oven, where it must remain till the morrow to cool."

Fig. 2235, *a* to *j* show the forms assumed by a ball of molten glass in the manufacture of a wine-glass. *a* shows the ball as taken up on the point, heated nearly to redness, of the blowing-iron. After being rolled on the marver and slightly expanded by blowing, it takes the shape *b*, when it is farther shaped and flattened by the battledore, as represented at *c*; a solid ball is then attached *d*, which is by the lathe or the use of the pucellas while being rotated on the glass-maker's chair formed into the stem *e*. To this a globe is attached, which is opened out and flattened by the pucellas while being rapidly rotated on the chair constituting the foot, as shown at *f g*. A small knob of glass is now by means of the pontil attached to the foot *h*, after which the cold pucellas are applied at the dotted line shown in *h*, after which the bowl is sheared *i* preparatory to flashing and finishing. The finished glass *j* is then taken up by means of a forked rod and transferred to the annealing arch.

In making a ringed decanter, the ball *k*, after being slightly distended, is swung round, causing it to assume the shape *l*; this is farther expanded and battledored at the end, taking successively the forms *m n*, the pontil is attached to the bottom and the neck broken off at the point indicated by the dotted line, and the mouth warmed up and shaped. The rings are formed by taking up small quantities of glass on the pontil and applying them as shown in *o p* to the neck of the decanter, which is rotated for the purpose.

Glass-ce-ment'. To stop cracks: —

Dissolve caseine in cold saturated solution of borax, and with this solution paste strips of hog's or bullock's bladder (softened in water) on the cracks of glass, and dry at a gentle heat; if the vessel is to be heated, coat the bladder on the outside, before it has become quite dry, with a paste of a rather concentrated solution of silicate of soda and quicklime or plaster of paris.

To unite broken parts: —

Two parts isinglass are soaked in water until well swollen, the water poured off, and the isinglass dissolved in warm alcohol; one part mastic is dissolved in three parts alcohol and added to the above solution, then one part of gum ammoniacum is added. The solution is well shaken and evaporated to the consistency of strong glue, then allowed to cool and solidify. When used, both cement and articles to be mended must be warmed. See also p. 507.

Glass-cloth. (*Fabric.*) A fabric produced by interweaving fabrics of glass, which are, in a very attenuated state, extremely flexible.

Glass-coach. A carriage of the superior order. The term is nearly obsolete, but it originally expressed that the vehicle had glass windows instead of opaque panels or curtains.

Glass-col'or-ing. Tinting glass by incorporating metallic oxides in its substance.

Articles which exhibit different colors upon the same specimen, and at different depths in the thickness of the glass, are formed by dipping the article, first made in white, transparent glass, into a pot of fused, colored glass. A coating adheres, and is afterwards cut away in portions, so as to expose the clear glass.

The colors are obtained by the following: —

Oxide of cobalt imparts deep blue.

Dioxide of copper imparts ruby red.

Protoxide of copper imparts green.

Protoxide of iron imparts shades of green.

Peroxide of iron imparts yellow brown.

Oxide of gold imparts ruby red.

Yellow oxide of iron, muriate of silver, oxide of zinc, and white clay, impart a yellow tinge; oxide of cobalt, oxide of manganese, and oxide of iron, impart a black tinge.

Red oxide of iron prepared by nitric acid and heat imparts red.

Purple of Cassius, precipitated from muriate of gold by protomuriate of tin, imparts violet.

Oxide, chloride, or phosphate of silver imparts yellow.

Peroxide of manganese imparts a shade of violet.

Oxides of chromium impart shades of green and red.

Uranium imparts opalescent yellow.

Binoxide of tin imparts opalescent white. In excess, opaque enamel.

Arsenic imparts bluish-white opal with changeable red tints.

Green may be obtained by staining one side of the glass blue, the other yellow.

Orange by similar combination of red and yellow.

Colored glass is known as *flashed*, or as *pot-metal*: in the former case a film of colored glass is laid over the white; in the latter, the color is stirred up with the *metal* in the pot, imbuing its whole substance.

Glass-cut'ting. Glass was known to the ancient Egyptians and Assyrians, and the art of gem-cutting was also known; the engraved gems of the Jewish high-priest's breastplate were cut by artists trained in Egypt.

Glass was cut upon a lap by the Greeks, and Pliny refers to the same, Book XXXVI. 26.

It has been affirmed that the art of glass-cutting was invented at the beginning of the seventeenth century by one Caspar Lehmann, of Prague, who was patronized by the Emperor Rodolphus II. Schwanhard, an apprentice of Lehmann, removed to Nuremberg, where he worked for many of the principal nobility, and hence this city acquired the reputation of being the birthplace of the new art; which was afterward much improved by the introduction of new tools and cheaper methods.

Previous to this, however, figures had been cut or engraved on glass by means of the diamond. The first mention of writing on glass with the diamond only dates back to the time of Francis I. of France (1520), but about the year 1562 festoons and other ornaments cut with a diamond were very common on Venetian glasses, which at that period were accounted the best.

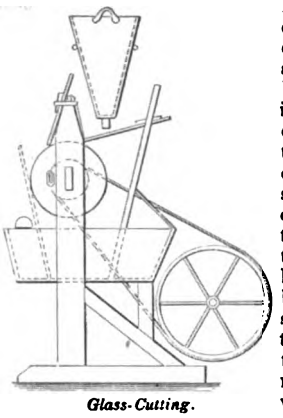
What is known commercially as "cut-glass" is glass with incisions and ornaments with smooth surfaces, appearing as if cut by a sharp instrument. This operation is chiefly confined to flint-glass, which, being more tough, soft, and brilliant than the other kinds, is more easily wrought, and produces specimens of greater luster. An establishment for cutting glass contains a great number of small wheels, of stone, metal, and wood, which are made to revolve rapidly, by a steam-engine or other power. The cutting of the glass consists entirely in grinding away successive portions, by holding them upon the surfaces of these wheels. The first or rough cutting is sometimes given by wheels of stone, resembling grindstones. Afterward, wheels of iron are used, having their edges covered with sharp sand, or with emery, in different states of fineness. To prevent the friction from exciting so much heat as to endanger the glass, a small stream of water continually drops upon the surface of the wheel. The last polish is given by brush-wheels, covered with putty-powder, which is an oxide of tin and lead.

The customary grinding and polishing of glass articles for various uses is effected by revolving

Digitized by Google

wheels of iron, stone, or wood, horizontally mounted, and supplied with a stream of water from a hopper or can above the wheel. The water is led by a sloping channel to the upper edge of the wheel, and a slightly sloping board is placed just in front of the point of its delivery to distribute it equally over its edge. A splash-board in front catches the water as thrown off by centrifugal force, and leads into a trough beneath. A second splashboard is sometimes placed in front to protect the workman from wet. The wheels employed are generally from six to twenty inches in diameter; they are mounted on separate spindles, so as to be exchangeable, and have flat, rounded, angular, or concave edges.

Fig. 2236.



Glass-Cutting.

The two former are used for producing the flat or slightly concave faces of the work, called *flutes;* the angular produce the angular grooves or *splits* on the sides of decanters and similar objects, and the concave form the convex ribs called *pillars.* The wheels for first or rough grinding are of iron, and a considerable quantity of sand is employed; the work is then smoothed upon fine grit stones, rendered circularly true and very smooth, less water and no sand being used; after which they are polished upon wooden wheels with pumice and rottenstone and water, and the final luster imparted by wet putty-powder applied on similar wheels.

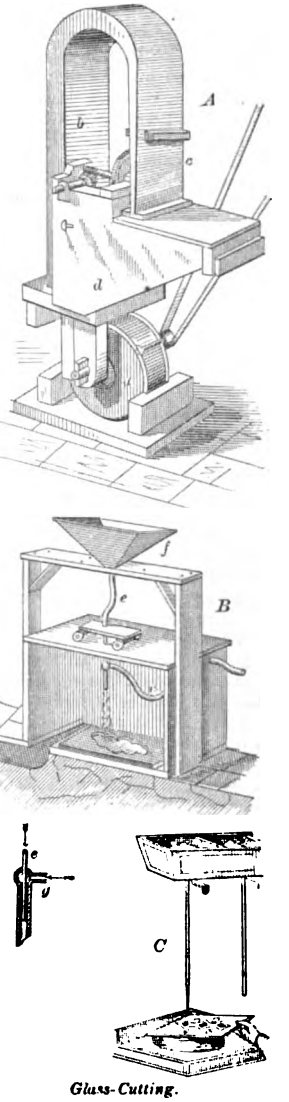
Tilghman's process for cutting glass or stone by means of a blast of air or steam carrying a stream of sand is adapted for piercing or for engraving the surface, and has many adaptations. In Fig. 2237, *A* is an apparatus for roughening sheet-glass. The air-blast is produced by the fan *a* below, and the air rises through the curved tube *b*, carrying the sand up with it, which is thrown into the air-tube by an endless belt of scoops arranged in the lower part of the angular box *d*. The sand is carried up by the air and brought over and down the front air-tube *c*, where it discharges with great force upon the surface of the glass, which is contained within the front box, and is carried by a belt gradually forward under the sand blast. The sand falls from the glass into the lower part of the angular box, whence it is scooped and thrown again into the air current.

Another form of apparatus for boring or engraving is shown at *B*, and the sand is driven in this case by steam, on the principle of the injector. The sand descends through a tube *e* from the hopper *f*, and in its course the vertical sand-pipe is joined by a lateral steam or air pipe, which gives a sudden impulse to the sand and drives it down upon the glass below with great force. The sand-tube is flexible, its extremity is carried on rollers, by which it may be moved back and forth to suit the requirements of the work.

C is still another form, in which corundum-powder is dropped from a hight upon the surface of glass to roughen or engrave it.

In each of the cases cited, the abrading material is directed by a tube upon the part desired to be bored or cut, the plate, if necessary, being moved beneath the sand-blast so as to bring each part in succession under the action of the cutting particles. When a pattern is to be engraved, a portion of the surface is protected by paper, oil-paint, a sheet of rubber, cloth, or lace, as the case may be. The sand bounds from these resilient materials, but indents the glass or stone with its points and edges, so as to roughen and gradually wear away the face, or even bore through it if the process be long continued. With a steam jet of 300 pounds' pressure, a hole 1½ inches in diameter was cut through a piece of corundum 1½ inches thick in 25 minutes. The rate is dependent upon the hardness of the material to be cut, the force of the blast, and the sharpness of the powder; the latter is much dependent upon its hardness, as corundum will outwear mere quartz sand.

Fig. 2237.



Glass-Cutting.

This beautiful process has many applications. Glass partially protected by a fern-leaf receives a frosted ground leaving a bright leaf; protected by wire gauze it may be turned into glass gauze. Ornamental letters may be made on glass, marble, or granite, either bright on a rough ground, or conversely. It has even been used to etch through negative films of bichromated gelatine, the penetration being greater in proportion to the thickness and hardness of the film.

Glass may be cut by a jet of hot air or gas, directed upon the object in the line of the desired fracture. This is then damped, and the glass contracts and divides on the line. The same may be done by a hot poker carried along the line to be broken; commence with a file cut to start the crack, apply the poker and the crack will follow the iron.

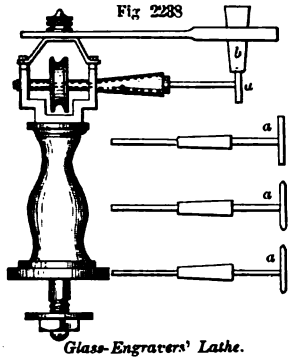
Glass may be readily drilled by a hard steel drill kept moist by turpentine. Dilute sulphuric acid or carbolic acid are good lubricants. It is said that at Berlin glass castings for pump barrels are drilled, planed, and bored like iron ones, and in the same lathes and machines, by means of sulphuric acid. See also GLAZIER'S DIAMOND.

Digitized by Google

Glass-en-am'el. This is applied to a semi-lucid or an opaque glass, which owes its milkiness to the addition of binoxide of tin. The transparencies which are hung in windows or form shades for lamps are of the semi-lucid character, and are miscalled *porcelain transparencies*. Watch-dials have an opaque, glass-enameled face on a metallic backing. See ENAMEL.

Glass-en-grav'ing. The engraving of flint-glass is substantially the same as the ordinary glass-cutting, but is of a more delicate character. It is effected by the use of very small disks, generally of copper, and moistened at the edges with emery and oil.

Fig 2238



Glass-Engravers' Lathe.

Bodier's improvements (French) in glass-engraving were made in 1799. The engraver sits at a small lathe with a little rack before him, containing about a score of the copper disks, varying in size from the diameter of a cent down to one-fiftieth of an inch, each mounted on a spindle and sharpened on the edge. He paints a rough outline of the design on the surface of the glass, and selecting a disk he touches the edge with emery and oil, inserts it in the mandrel, sets it spinning, and holding the glass against it from below, the little wheel eats its way in with astonishing rapidity. The glass, held lightly in the hands, is shifted about continually, till all the greater parts of the figure are worked out; then, for the lesser parts, a smaller disk is used; and at last the finest touches, such as blades of grass, the tips of antlers, eyebrows, and so forth, are put in with the smallest. Every minute he holds the glass up between his eye and the light, watching the development of the design; now making a broad excavation, now changing the disk every ten seconds, and giving touches so slight and rapid that the unpractised eye can scarcely follow them.

The illustration shows the lathe-post with its band-pulley, spindle, and disk *a* in position. *b* is a slip of wood mounted on an arm, and designed to keep the wet powder from being thrown against the operator. For polishing, a leaden disk and pumice-powder are used.

Glass-fur'nace. There are several furnaces in a house for making *crown-glass*:—

The *reverberatory-furnace*, or *calcar*, for fritting or calcining the materials. Also known as the *fritting-furnace*.

The *glass-furnace* containing the pots in which the materials are melted.

The *blowing-furnace*, at which the pears of glass are enlarged into globes.

The *bottoming-hole*, where the globe is flattened.

The *flashing-furnace*, where it is expanded into a circular plate.

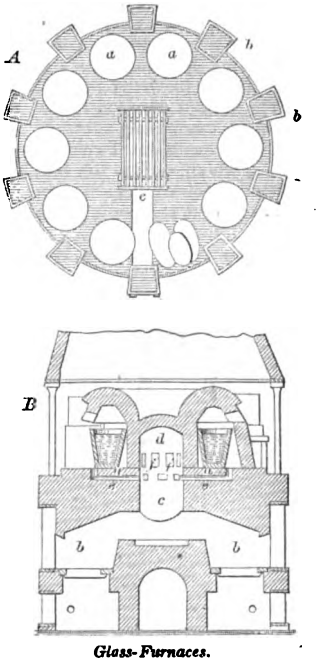
The *annealing-arch* or *leer*, where it is allowed to cool gradually.

The *reverberatory-oven*, where the pots are heated and seasoned.

Fig. 2239, *A* is a plan of the furnace in which the frit in pots is converted by fusion into glass.

a a, etc., are the flues between which the pots are placed, resting on the intervening spaces, so that each flue heats one side of two pots. The working holes *b b*, etc., are opposite each pot and between the flues. *c* is the grate. Flame and smoke pass through apertures called *linnet-holes* at the upper part of the sides of the furnace, which has a dome-shaped top. The furnace *B* has an annular bed with projections *a a* on which the crucibles rest. It is provided with two fireplaces *b b* communicating with a central flue *c*, through which the caloric current passes to an upper chamber *d*, whence it is distributed to the crucibles by the openings *e e f f*.

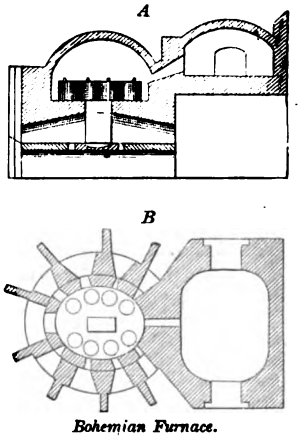
Fig. 2239.



Glass-Furnaces.

Fig. 2240, *A* is a longitudinal section, and *B* a plan of a Bohemian furnace employed in making window-glass. Above the vaulted ash-pit is the fireplace, having three compartments from which the heat passes through a central opening to the oven containing the glass-pots, which are placed closely together for economy of space. The pots are introduced through a front opening which is then bricked up. The working-holes are between the pillars of the structure. A flue conducts the heat to the annealing-stove, exterior to which is usually a drying-kiln, not shown in the figure, and there are adjoining stoves called *arches* for drying and annealing new pots.

Fig. 2240.



Bohemian Furnace.

Glass-gall. Scum on the glass, in the pot. *Sandiver.*

Glass Grind'ing and Pol'ish-ing. Plate-glass from the table requires grinding and polishing, which is performed by machinery. The under plate is imbedded in stucco on a solid table, and the upper one in a cast-iron frame, which has a motion around its own center and around a point on the lower plate. The latter is on a movable table, and has a slow motion in the direction of its length and its breadth. Moistened sand is applied between the two. Afterwards different grades of emery are used.

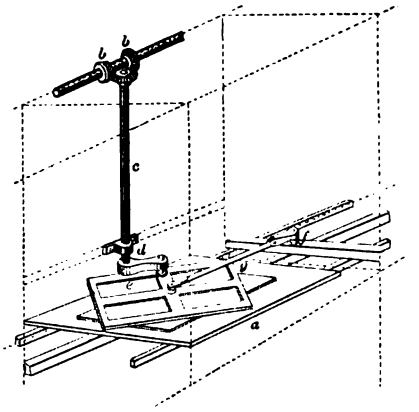
Digitized by Google

The polishing is effected by rubbers of hat felt or leather, with a paste of colcothar and water. Finally, a putty, oxide of tin, is used.

Fig. 2241 illustrates a machine for grinding and smoothing the plates to a true and even surface preparatory to finally polishing them.

The dotted lines indicate the framework of the machine supporting the bed *a*, to which a sheet of glass is cemented. Two bevel wheels *b b* rotate the axis *c*, which carries the crank *d* attached to one side of the movable table *e*, imparting to it a circular motion about the point *f*, where the radius-rod *g* is

Fig. 2241.



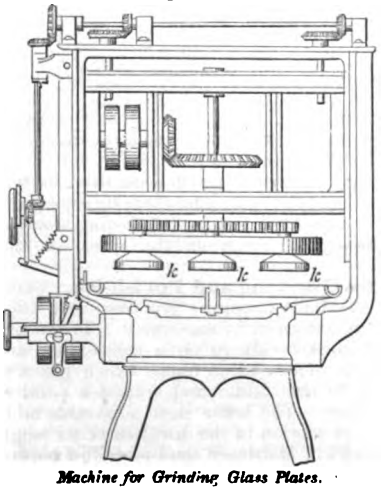
Glass-Polishing Machine.

pivoted; the bed *a* also has a slow longitudinal reciprocating movement imparted from a bar beneath. The lower part of the table *e* is faced with slate, to which a sheet of glass is cemented. Clean sharp sand and coarse emery are used for grinding, and finer emeries for smoothing; the apparatus being carefully washed at each change from coarser to finer material.

By the combined rotary and longitudinal movement the abradants are caused to operate with equal energy on every point of the plates. Weights are placed upon the back of the table *e* to insure sufficient pressure.

The final polishing is completed by leather-covered rubbers attached to reciprocating rods; the glass being fixed upon a table having a slow transverse movement so as to present every part of the surface of the glass successively to the rubbers.

Fig. 2242.



Machine for Grinding Glass Plates.

Old plate-glass is usually repolished by hand, the rubber being attached to the lower end of a pole suspended from a horizontal spring overhead, which gives an adequate pressure on the glass, the workman having merely to push the rubber backwards and forwards. The polish attained in this way is inferior to that produced by machinery.

Fig. 2242 shows a glass grinding-machine in which the plate to be ground is held upon a reciprocating table under the rotary grinders *k k k*, whose supporting frame is capable of vertical movement in guide-ways, an automatic downward movement being imparted to the grinders at the end of each movement of the carriage by the action of gearing upon the screws on which the frame is hung.

Glass-house. A place where glass is made.

Glass'ing. (*Leather.*) The operation of dressing leather on the grain side by a tool consisting of a glass slip set in a wooden handle.

Glass-lined Pipe. One in which the metal of the outer pipe is protected from corrosion by any liquids, except strong alkalies, or hydro-fluo-silicic acid. The glass lining is held in the outer metallic pipe, which is usually of iron, by an intermediate lining of cement, or plaster of paris, or similar substance, which lining serves to hold the glass in place and protect it against injury from unequal expansion of the glass and metal, besides acting as a non-conductor of heat.

Glass-mak'er's Chair. A seat having two arms upon which a glass-blower rolls with the left hand

Fig. 2243.

Glass-Maker's Chair and Marver.

his pontil or blow-tube, while with his right he fashions the bottle, lamp-shade, or other article he is making, by means of the *pucellas*.

Glass-mak'er's Soap. A name given to manganese, from its cleansing action in its association with glass-making materials.

It is used to rid the materials of color arising from carbonaceous matters and protoxide of iron. An excess of it gives a purple tinge to the glass; much admired by some, and supposed — by some — to have a specific effect in urging vegetation in conservatories.

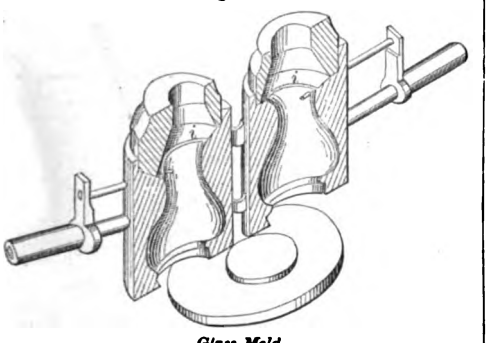
Glass-met'al. Glass in fusion in the pot.

Glass-mold. A metallic shaping-box in which glass is pressed or blown to form. In the case of solid articles, the glass for the knob or ornament is

Digitized by Google

placed in a plastic condition in the mold, and then a plunger drives it forcibly into all the recesses of the mold. After a few moments of "setting," the mold is opened, and the object is taken out and carried to the annealing-oven. This is the usual mode of making glass insulators for telegraph-wires, paper-weights, drops for chandeliers, and the solid kind

Fig. 2244.



Glass-Mold.

of inkstands where the glass is so much in excess of the ink-hole. The latter is made by a plunger, which is driven into the plastic glass in the mold. See GLASS-PRESS.

Hollow articles, such as fruit-jars, may be made by blowing (see GLASS-BLOWING), the *blowing-tube*, *shair*, and *marver* being the principal tools employed, the jar being held by its lip end while being blown, and then by transferring the *pontil* to the bottom while the lip is finished by the *shears* or the *pucell us*, or the jar may be grasped by the *snap-dragon*, if preferred.

The modern fruit-jar has usually some arrangement for locking down the lid or cover, and involves a threaded neck or one with lugs or projections. These can be made by tongs, which clasp the neck of the bottle, but not so readily as by clamping the bulb of glass in a mold and then blowing it so as to expand fully against all parts of the interior of the latter. The mold is then opened, and the formed article removed to the *leer*. Fig. 2244 shows a glass-mold open, the side parts being hinged together over the plate which forms the bottom. In this example, the shoulder *i* really forms the lip of the ware, and the flaring recess above it is the *blow-over*, in which superfluous glass is received, the shoulder affording a thin point where the portion readily breaks off.

Fig 2245.

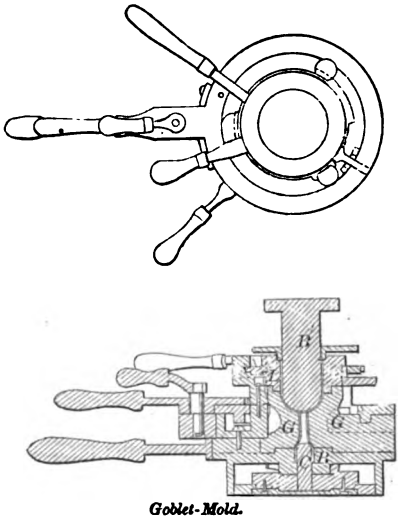
Glass-Blowing in Mold.

Fig. 2245 shows the man at work. He has taken the pontil from the boy, who had dipped the proper amount of glass out of the pot in the furnace, and had blown it partially and rolled it on the *marver;* the workman blows it still farther, rolls the pontil on the chair-arm while he fashions it by the shears, which are seen lying on the bench, and then slips it into the open mold and closes the latter by a spring while he blows it to its final expansion.

In some cases water is made to circulate through the molds, to abate the heat and allow the work to proceed more speedily. Molds are sometimes made to be closed by a treadle. See Plate XX.

Fig. 2246 shows a mold for making tumblers, — foot, stem, and bowl. The complication of form and the hollow character of the bowl require that a number of parts shall be employed, so that the ware may be taken out after molding. The foot is molded in cup form by the plunger *C* and matrix *B*, and is afterwards expanded. The stem-mold consists of three sections *G G*, which open radially over

Fig. 2246.



Goblet-Mold.

the foot-mold. The body matrix *L* is held down upon the stem sections by a clamp. The portions have separate handles. For bottles which contain the names of the contents and medicines, the interior surface of the mold has intaglio engraving with the inscription, medallion, and what not.

Glass Mo-sa'ics. Glass mosaics are constructed as follows: —

In the first place, the materials of glass are mixed with various coloring materials, chiefly metallic oxides, so as to form opaque colored enamels; these enamels are cast into slabs or flat cakes, and the slabs are cut into very small cubes or rectangular pieces. Not only is every color imitated, but every gradation of tint in each color, insomuch that at the great mosaic establishment at Rome, maintained by the Italian government, they have no less than *thirty thousand* different tints of colored enamels, all classified and registered. With these little colored cubes a picture is built up, copying some celebrated work of the Italian or other masters. The pieces are inserted, one by one, in a bed of cement, which dries to extreme hardness; each piece is ground at a kind of lathe to the exact shape required by the particular tint in each part of the picture; and when the picture is completed by this extremely slow process, the surface is ground down and polished.

The two specimens of glass mosaic described ded Winckelmann and Count Caylus, in the last closed,

Digitized by Google

seem to have been of a somewhat different kind, for they presented a complete picture on each surface. They consisted of colored glass fibers fitted together with the utmost exactness, and cemented by fusion into a solid mass.

Glass-ov'en. A heated chamber in which just-made glass in sheets or ware is placed to cool gradually. A *glass-annealing furnace;* a *leer.* See ANNEALING.

Glass-paint'ing. *Glass-painting* is thus distinguished from *glass-staining:* the former has a design painted upon it with colors which are burned in; the latter receives its color in the process of manufacture, or the separate pieces are colored after having been cut to the required shapes out of white glass.

In one case it is a painting of enameled colors on sheets of glass.

In the other, it is a painting made up of pieces having the required colors, fitted together and held by leaden *cames.* See GLASS-STAINING.

Even with this distinction the subjects become somewhat involved as the processes have been combined.

The growth of the art has developed four modes: —

1. The *mosaic.* This is the earliest, and was known in Byzantium at an early date. It is not known that colored-glass windows were known in Rome, though white-glass windows are found at Herculaneum and Pompeii. The art is supposed to have been brought from Byzantium to Venice and Marseilles, and was practiced by the Saracens throughout the cities of the East.

Stained-glass windows were in the basilica of St. Sophia and other churches in Constantinople, in the sixth century; painted glass windows not till two or three centuries later, notably in the reign of Charlemagne. Some windows executed in the tenth to the twelfth centuries are yet in existence in Europe. The fifteenth century (*cinque cento*), under Albrecht Dürer and others, produced many beautiful specimens, some of which still remain; for instances, the Church of St. Jacques at Liege, and windows ornamented by the Crabeths at Gouda, in Holland.

2. The *mosaic stain.* In this mode the window is made up of detached pieces, as in the *mosaic;* but the shades are given by a stain of brown, which seems to have been the first color which the artists succeeded in *firing* on to the pieces of glass.

3. The *enamel.* By this all the required colors (see GLASS-COLORING) are painted upon the same piece of glass and fired in the kiln, producing the effect of an oil-painting. William of Marseilles (1475–1537) was a distinguished enameler on glass.

4. The *mosaic enamel.* In this mode *colored* glass is used as a groundwork to paint on, instead of *white.*

Glass-pa'per. The fragments of broken wine-bottles, etc., are carefully washed to remove dirt, the glass is crushed under a revolving stone and sifted into six sizes, as in manufacturing emery. It is sifted through sieves of wire-cloth, which are generally cylindrical, like the bolts of flour-mills. The cloths have from sixteen to ninety wires to the inch.

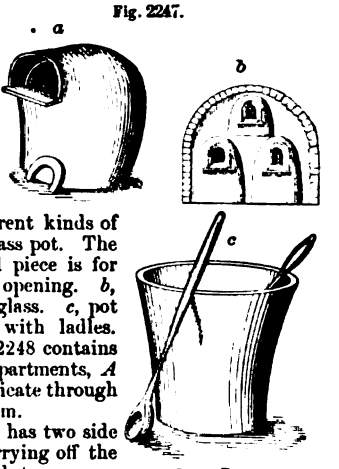
A surface of thin glue is spread on the paper, and the pulverized glass dusted over it with a sieve.

Sometimes two coats of glue and glass are applied. Under Edwards's patent (English), cotton cloth is used instead of paper.

Emery, sand, and powdered flint are used instead of glass, and constitute *emery, flint, sand* paper.

Glass-pot. The pot in which the *frit* is fused ... glass. They are made of pure refractory clay, ...ith about one fifth its weight of old pots pulverized by grinding, are built up instead of being formed on a mold, and baked by being subjected to a white heat. Different forms are used for different kinds of glass. *a,* flint-glass pot. The horseshoe shaped piece is for contracting the opening. *b,* pots for colored glass. *c,* pot for crown-glass, with ladles. The pot in Fig. 2248 contains two or more compartments, *A B,* which communicate through openings at bottom.

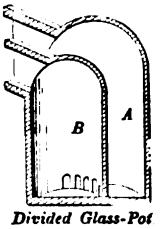
Fig. 2247.



Glass-Pots.

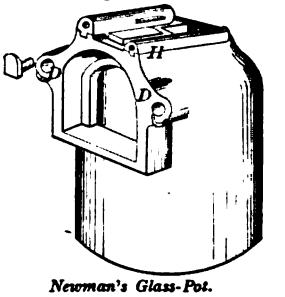
Newman's pot has two side flues *D D* for carrying off the heated gases, and two upper flues *H H* for supplying hot air to insure more speedy liquefaction of the charge.

Fig. 2248.



Divided Glass-Pot

Fig. 2249.



Newman's Glass-Pot.

Glass-press. A device to apply pressure to glass in a mold while in a plastic state. In the press shown, the plunger is hung on a sliding head moving upon guides and operated by connection with a rock-shaft. The cover of the mold is held down by followers, and the mold slipped in and out at the requisite periods. Power is applied by a lever, which is counterpoised by a weight.

Glass-roll'ing. About 1849, Bessemer obtained a patent in England for a process of rolling glass, to make plate-glass and avoid the undulating surface incident to blown window-glass.

Messrs. Chance, of Birmingham, expended £100,000 in trying to perfect the machinery therefor, but failed to accomplish it, and abandoned the enterprise. The glass, in its pasty condition, was passed from a hopper between two rollers on horizontal axes and was received on a flattening-table.

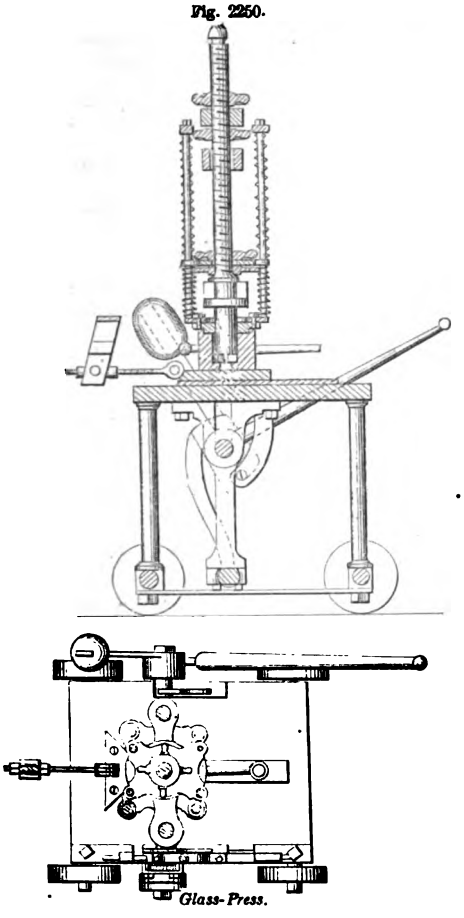
Glass-sil'ver-ing. Glass for mirrors or ornamentation is silvered by one of two methods; the first is merely factitious: —

1. *The amalgam method.* A sheet of tin-foil is spread evenly on a smooth marble table; on this mercury is evenly spread with a hare's foot until the amalgam is produced. Mercury is then poured to a certain depth, — the English rule is, "as deep as the thickness of a crown-piece," — and the clear, dry sheet of glass slipped over the surface of the liquid metal, excluding all bubbles of air, or dirt, or floating dross. Pressure and standing in a slanting position to drip conclude the operation. See MIRROR; SILVERING; PLATINIZING.

For convex and concave surfaces, a mold of plas-

Digitized by Google

Fig. 2250.



Glass-Press.

ter is formed to fit the amalgamated foil to the surface.

Globes and hollow vessels are silvered by application of amalgam, such as lead, 1; tin, 1; bismuth, 1; melt; cool to lowest point they will remain liquid, and add mercury, 10. Stir with an iron rod.

Or, lead, 1; tin, 1; bismuth, 2; mercury, 4. Warm the vessel, pour in the amalgam, turn the vessel round and round, and, at a certain heat, the amalgam will be found to adhere to the glass.

2. *The humid way.* A mixture of nitrate of silver, 1, liquor ammonia, ½, water, 2, is settled and filtered, and to this is added alcohol, 3, and a few drops of oil of cassia. This is floated on the glass, being restrained by a wall of putty. Pour off, and varnish the metallic surface. Hollow vessels are silvered by pouring in the solution and turning them round and round. Other oils or grape-sugar are also used.

Vohl has a solution of gun-cotton in caustic potassa, to which is added a solution of nitrate of silver, followed by sufficient liquor of ammonia to redissolve the precipitate. The resulting argentiferous liquid is applied to the glass, which is heated over a water-bath until effervescence ensues, when the silver is deposited.

Cooley recommends: Mix saccharic acid with solution of nitrate of silver, decant, apply, precipitate by solution of ammonia, and heat to render deposit brilliant.

Glass-soap. Peroxide of manganese used to remove from glass the green color due to the presence of iron.

Glass-sol'der-ing. Guinand, of Brenetz in Neufchatel, acquired the art of soldering together pieces of glass. When the line of junction was marked by globules of air or particles of sand, he ground out the latter on the wheel, then replaced the mass in the furnace, so that the vitreous matter might expand and fill up the spaces. He thus combined good pieces of glass, so as to build up lenses of flint-glass of fine quality. Guinand joined Frauenhofer in Munich in 1805, and returned to his native canton in 1814, where he died, and was succeeded in his business by his sons.

Glass-spin'ning. Brunfaut of Vienna works a process in which he makes curled or frizzled yarn of glass. The composition is a secret. One workman with a wheel having a diameter of 5 Austrian yards will spin 3,500 yards per minute. It is used for many descriptions of fabric and for many purposes, cushions, carpets, table linen, shawls, neckties, etc.

Bonnet's European patents for cloth of glass are dated in 1837. The warp is of silk, the weft of glass spun by steam-engine power, about sixty threads to the inch.

Glass-stain'ing. *Stained-glass* is colored in the process of manufacture.

Painted-glass is a colored or white glass on which a metallic paint is laid, and subsequently fixed by fusing, — *fired in*, as it is termed.

Stained-glass windows are executed in pieces of colored glass, which are cut to the shape of the patches of color in the original design and are brought together in the manner of *mosaic*. These pieces are set in leaden frames called *cames*. This is the most ancient practice and is still in use.

The design is first sketched on paper, the colors and the exact arrangement of the pieces are then determined, so that it may be known just how many will be required, and their proper shapes and sizes. Some windows are composed of more than 10,000 pieces.

The material used is crown-glass made in large sheets expressly for the purpose. The greater portion of that used in this country is American, but some of the very fine colored glass, as ruby, blue, purple, and green, is imported.

The sheets are cut to their proper shape and size with a glazier's diamond, and then painted by laying on with a flat brush a thin, uniform coat of the proper color. These colors are all mineral, as they have to be long subjected to an intense heat in order that they may become firmly united to the substance of the glass.

Crown-glass is used as being less fusible than that containing a large proportion of lead. Being comparatively intractable, it does not fuse when the enamel colors melt and unite with it through the medium of the flux with which they are incorporated.

Reds and yellows are produced from silver and antimony; another red, from oxide of iron; white, from block-tin; black, from manganese; green, from copperas; and purple, from gold. See GLASS, COLORING.

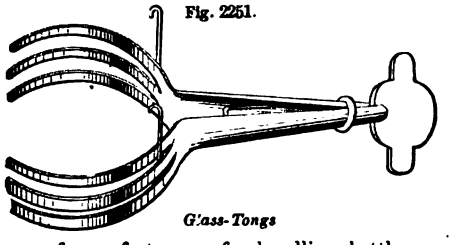
The colors are pulverized and mixed with a flux composed of red lead, flint-glass, and borax, which are melted together in crucibles. This composition made into a paint is laid on as previously described, and allowed to dry, when the sheets are transferred to the kiln, an oven of brick about 5 × 4 feet, in dimensions, and provided with shelves made of iron plate on which the pieces of glass are piled twelve or fifteen deep, when the doors are closed,

Digitized by Google

and a heat sufficient to heat the glass red hot is maintained for eight hours, when the fires are drawn and the glass is allowed to slowly cool for forty-eight hours for the purpose of annealing it. By the fusion of the flux and partial surface fusion of the glass, the colored coating is thus inseparably united to the latter.

Glass-tongs. Grippers for hot bottles, etc., in

Fig. 2251.



Glass-Tongs

course of manufacture, or for handling bottles containing heated or freezing mixtures.

Glave. A weapon formerly used, consisting of a curved blade on the end of a pole.

Glaze. A vitrifiable composition for covering earthenware or porcelain. Glaze on earthenware has several objects: —

1. To render the ware impermeable to liquids.
2. To impart luster.
3. To preserve colors and patterns.

It must adhere firmly to the ware, and expand and contract in the same proportions therewith, so as to avoid cracking and scaling.

It should resist acids, so as not to be dissolved by vinegar and other acid substances.

It should not have such an affinity for the ware as to sink into the latter when in a biscuit condition.

Glazes are of several kinds: —

Felspar is the base of a vitreous glaze which melts at a high temperature. It is found in natural combination with quartz; or is mixed therewith, sometimes with lime. It is principally used on porcelain or china.

A second class of glazes includes salt, potash, boracic acid, phosphate of lime, and sulphate of baryta; used on stoneware.

A third class is a glass, mainly consisting of silica and lead.

The fourth class includes the oxides of lead, tin, manganese, and copper.

Glazes are further subdivided into —

Transparent.

Opaque.

Colored.

Transparent glaze is a glass.

Opaque glaze is compounded with oxide of tin.

Colored glazes derive their peculiar tints from metallic oxides, manganese, copper, iron, cobalt, chromium, etc. See ENAMEL.

Glaze is applied in various ways: —

Some common earthenwares are glazed by throwing salt into the kiln at certain stages of the firing process. A partial vitrification of the surface takes place at the expense of the silica of the paste.

The salt is sublimed, producing a saline atmosphere throughout the kiln, the soda enters into combination with the silica of the ware, forming for the alumina, etc., a flux; and producing a glassy surface on the ware.

Porcelain and fine ware, while in the biscuit condition, are dipped into a thin solution of the glaze. The ware in this condition is very absorbent, and the water passes into the biscuit while the body of the glaze adheres to the surface.

In this case the glaze consists of vitreous matter fritted in a furnace and reduced to powder. The powder is stirred up in water and held suspended while the ware is dipped.

Articles only requiring an interior glaze receive it by pouring a quantity into them, swashing it around and pouring out the surplus.

Other ware is glazed by means of a brush.

Glazes are ground in water to a thin cream, forming a *slip*, in which clay-ware in the form of *biscuit* is dipped. The heat of the kiln fuses the *glaze*.

Glazes are white or colored, they differ only in that the latter have coloring ingredients.

For earthenware. *Lead glaze:* white lead, 53; quartz, or ground flints, 36; felspar, 16; white flint-glass, 5.

For chemical vessels. Fine sand, 48; potassa, 39; lime, 9; niter, 4. Oxide of tin or cobalt may be added to correct color.

For porcelain. Felspar, 27; borax, 18; fine sand, 4; niter, soda, and kaolin, 3; mix, frit, powder, and add calcined borax, 3.

For painted stoneware. White felspar, 26; soda, 6; niter, 2; borax, 1; frit. Of the product take 13; red lead, 50; white lead, 40; ground flint, 12.

M. Richard, ceramic manufacturer at Saint-Christophe, near Milan, has communicated to the Society of Encouragement, Paris, his process for varnishing pottery, and applied by him to different products exhibited at the Champ de Mars (Group III. Class XVII., Italian Section). The following are the ingredients and their proportion to be fritted: Carbonate of soda, 1.000; boracic acid, from Tuscany, 0.800; kaolin, 0.125; carbonate of lime, 0.250; sulphate of lime, 0.250; crystallized felspar, 0.750; quartz from the Tessin, 0.280; fluate of lime, 0.150. Manganese of Piedmont is added to obtain the desired tint. The whole frit is ground fine, and then mixed with 110 parts of kaolin and 52 parts of felspar for every 460 parts of the above frit. It is applied as usual in glazing, but, as the specific gravity is less than the leaden coating, the same weight of the new glaze will cover a greater quantity of pieces.

Vitreous glazes originated with the Chinese, and passed from them to India, and successively to Persia, Arabia, Spain, Italy, and Holland.

Previous to the introduction of glazes, the Greeks and Romans covered their pottery with wax, tallow, or bitumen. The Peruvians used tallow spread upon the ware while hot and thereby partially carbonized. The Etruscan ware has a similar appearance. In Italy and Spain, ancient and modern, wine-jars are rubbed with wax to render them impervious to liquids.

Among the early instances of glazing may be mentioned the tomb of Sultan Mohammed Khoda-Bendeh, at Sultanieh in Persia. He was the 12th prince of the house of Genghis Khan, and died in 1316. The tomb has green enameled tiles on the outside and blue on the inside.

The "painted mosque" of Gour in India, built in 1475, derives its name from the number of glazed tiles with which it is ornamented.

The Caravansérai of Mayar, near Ispahan, built by the mother of Shah Abbas, about 1550, has a covering of green glazed tiles on the front of the principal gateway.

The Alhambra, a Moorish palace and fortress near Granada, was founded by Mohammed I. of Granada about 1253. Some of the rooms are ornamented by glazed tiles.

Coffins of green glazed pottery are found at Warka in Mesopotamia, and are ascribed by Rawlinson to the period of the Parthian occupation of that country. This is a startling supposition. The style of

Digitized by Google

ornamentation and the figures stamped upon them forbid the supposition that they were imported from China, and yet this single fact of glazed pottery in that place at that time is almost irreconcilable with the observed contemporary progress of the art of making pottery in general. See Fig. 1377, p. 587.

Glazed Board. A kind of mill-board having a hard, smooth surface, to give a smooth face to the paper or fabric pressed between such boards.

Glaze-kiln. (*Pottery.*) A kiln in which glazed *biscuit*-ware is placed for firing. It is analogous to the *glost-oven*.

Glaz'er. 1. A cutler's or lapidary's wheel of a grade between the grinding and the polishing. It is made of disks of wood so arranged as to present the grain outwardly, that is, radially. The wooden surface is fed with emery-cake. Mahogany, oak, apple, beech, or birch, are employed.

Other *glazers* have a covering of leather or a cap of lead or tin alloy to carry the emery for grinding or glazing cutlery.

Lapping is done on metallic wheels.

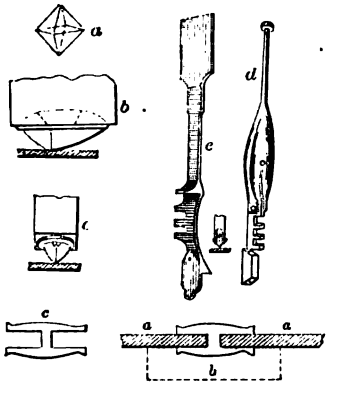
Polishing on leather-covered wheels.

Buffing on leather with rouge.

2. A calendering or calico-smoothing wheel.

Gla'zier's Di'a-mond. An implement for cutting glass consisting, as now universally made, of a handle, by which it is held between the fingers and guided, and having swiveled at its lower end a holder or block, in which a small diamond with one of its natural angles exposed is inserted. By this arrangement, invented by Joshua Shaw, the cutting edge of the diamond constantly tends to maintain its parallelism with the straight edge or pattern which guides it, so as to make a clean, smooth cut. The knack of using this tool properly, and judging of the proper vertical angle at which it should be held, requires some practice. The sound indicates whether or no a clean cut is being made. The normal crystalline form of the diamond is octohedral, and the faces are usually convex. Upon this latter peculiarity, according to Dr. Wollaston, its efficiency depends, the rounded edge slightly indenting the glass and then slightly separating its particles, forming a shallow fissure with a splitting rather than a cutting action, none of the material being removed. This fissure is readily extended through the glass, a slight degree of force serving to separate the two parts. He succeeded in producing the same result with several other hard gems by giving them the same form, but the natural edge of the diamond being so much harder and more durable, renders it much more economical than any other material for the purpose. *a* shows the primary crystalline form of the diamond, a regular octohedron. *b c*, diamonds with rounded faces forming a more or less acute angle. *d*, an improved form having teeth for breaking apart the two pieces after making the cut. *e*, an implement denominated the "universal glazing-tool," for cutting and setting glass. This has a small thin roller pivoted at its lower extremity, which in its passage over the glass separates the particles in a manner similar to the diamond.

Fig. 2252



Glazier's Diamond and Vise.

The spatula at the other end is used for puttying, etc.

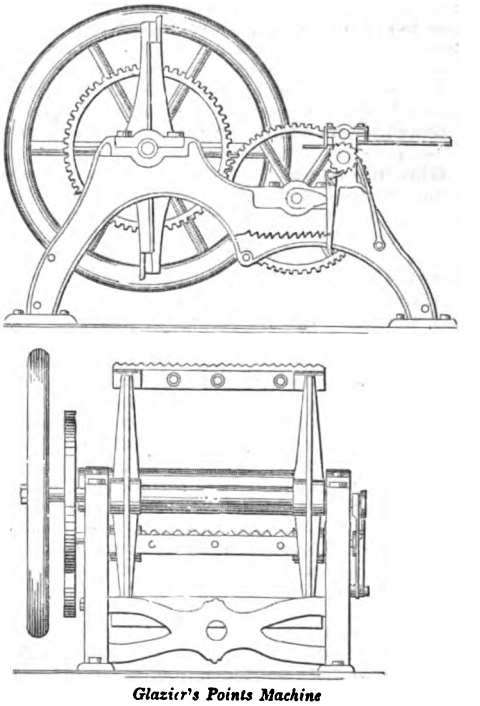
The diamond is crystallized carbon. Diamonds were first brought to Europe from the mine of Sumbalpoor. The Golconda mines were discovered in 1534. The mines of Brazil in 1728. Those in the Ural in 1829. The great Russian diamond weighs 193 carats; cost, £104,166 13*s.* 4*d.* in 1772. The Pitt diamond weighed 136 carats; sold to the king of France for £125,000, in 1720. The Koh-i-noor was found in 1550. It belonged in turn to Shah Jehan, Aurung-Zebe, Nadir Shah, the Afghans, Runjeet-Singh, and Queen Victoria, 1850. It originally weighed 800 carats, was cut down to 289 carats by an unskilful Italian, and then to 102¼ carats to perfect its shape. See DIAMOND.

Pliny speaks of *adamant* as the hardest of all materials, and it may mean the uncut diamond. We do not know that diamond-cutting was practiced, and it is not certain that diamond-dust was employed in gem cutting and engraving, although there are several indications of its use. He says: "Diamonds are eagerly sought by lapidaries, who set them in iron handles, for they have the power of penetrating anything, however hard it may be." He farther cites that all gems are engraved by the diamond.

A German authority states "they used, for the purpose of cutting sheet-glass, emery, sharp-pointed instruments of the hardest steel, and a red-hot iron by which they directed the rents at their pleasure."

An early notice of the use of the diamond in cutting, or rather scratching, glass is associated with a love-quarrel, in which Francis I. of France, 1520,

Fig. 2253



Glazier's Points Machine

Digitized by Google

wrote with a diamond set in a ring, on a pane of glass in the castle of Chambord, a couple of lines to Anne, Duchess of Estampes. It seems to have been the subject of a patent to Gaspar Lehmann of Prague early in the seventeenth century, and granted by the Emperor Rodolph II.

Gla'zier's Knife. A knife used by glaziers in clearing out the remains of old panes from the fillisters of sash, and puttying in new ones. Such knives are known as *hacking*, *stopping*, and *putty* knives.

Gla'zier's Point. A small, triangular piece of tin plate, employed to secure a pane of glass in the sash previous to puttying. They are made in a machine in which the sheet of metal is fed to the rotary cutters, and the points are cut off in two or more rows at each rotation. The face of the cutter is notched like a saw-blade, and snips from the edge of the plate a row of triangular pieces.

Gla'zier's Vise. (*Plumbing.*) An apparatus for forming leaden bars for the reception of window-glass. The bar is called a *came*, and the mode of glazing is called *fret-work*. The came is formed by drawing a plain bar of lead between two rollers *a a* (Fig. 2252), of thickness equal to that of the glass, and having corrugated edges which draw the bar forward between two pieces *b b*, causing it to assume the shape *c*. The whole device constitutes the glazier's vise.

Glaz'ing. 1. Placing panes of glass in sashes.

2. Giving a vitreous coat to pottery.

3. Polishing metal on a wheel dusted with polishing-powder.

4. Spreading a semi-pellucid cover over a painting to soften asperities.

5. (*Gunpowder.*) All good powder is glazed in order to enable it to more perfectly resist moisture and bear transportation. For this purpose the grains from the breaking rollers, after having been assorted by sieving, and while still containing three or four per cent of water, are placed to the amount of several hundred pounds in a glazing-barrel; this is journaled at the ends, and is caused to rotate for some ten or twelve hours, breaking off the angular projections of the grains and causing them to assume a smooth and glossy surface.

Pulverized plumbago is sometimes added to produce a deceptive appearance of high glazing.

Glaz'ing-ma-chine'. A press with two polished rollers to calender paper.

Glaz'ing-wheel. A wooden wheel covered with leather charged with emery, and used by cutlers, especially for grinding and sharpening knives, tools, etc.

It is also used instead of filing for leveling and surfacing many metallic articles; for removing the scale from casting, and for trimming small castings, such as builders' hardware.

A wooden wheel without any leather covering is used by lapidaries in smoothing soft and rounded stones. These wheels are fed with flour, emery, and water.

Glass-cutters employ similar wheels with pumice-stone and water for smoothing, or putty-powder and water for polishing.

These wheels, commonly called *glazers*, are made of wooden disks or quadrants, so arranged as to present the end of the grain outwardly. They are fed with emery-cake; and by cutlers the wooden surface is frequently used without any leather covering.

Globe. A sphere on which is represented the heavenly bodies; a *celestial* globe. A round model of the world, representing the land and sea, and usually the political divisions. A *terrestrial* globe.

A celestial globe was taken from Egypt to Greece, 368 B. C.

A terrestrial globe is said to have been made in the time of Anaximander of Miletus, about 550 B. C. This is highly improbable. The determination of the latitude and longitude of places was of a later date, and is a necessary incident of a terrestrial globe.

The celestial globe of Billarus was taken away from Sinope by Lucullus (STRABO). The same writer mentions the sphere of Crates; Cicero that of Archimedes. Perhaps this was a planetarium.

The planisphere of Dendera in Egypt is a circular diagram of the zodiacal signs, and the most ancient and interesting of all representations of celestial scenery.

Gerbert, who studied astronomy among the Saracens in Spain, and was afterwards Pope Sylvester II., A. D. 1000, used in his school at Rheims a terrestrial globe brought from Cordova.

"While Rome was asserting, in all its absurdity, the flatness of the earth, the Spanish Moors were teaching geography in their common schools from globes. In Africa there was preserved, with almost religious reverence, in the library at Cairo, one of brass, reputed to have belonged to the great astronomer Ptolemy (about A. D. 130). Al Idrisi made one of silver for Roger II. of Sicily (A. D. 1131), and Gerbert used one he had brought from Cordova in the school he established at Rheims" (about A. D. 975). — DRAPER.

The globe of Gottorp is a concave sphere, 11 feet in diameter, with seats inside for spectators. Its concavity represents the constellations of the heavens, and its exterior is a terrestrial globe. It was constructed after the designs of Tycho Brahe, and turned on its axis. Dr. Long's globe was 18 feet in diameter, and held thirty persons, who viewed it while it was in motion. Mr. Wyld erected in Leicester Square a globe 60 feet 4 inches in diameter. Its concavity represents the terrestrial surface. It was lighted by openings during the day and by gas at night. Its interior was occupied by ladders and platforms, from which its painted surface was viewed. It was closed in 1861.

Martin Behaim on his "world apple," the celebrated globe which he finished in 1492, and which is still kept in the Behaim house in Nuremberg, places the coast of China (by estimate), only 100° west of the Azores. Marinus of Tyre had advanced the Chinese coast to the longitude of the Sandwich Islands, being misdirected by the calculations in the Asiatic itineraries, and thereby giving to the old continent a breadth of 225° instead of 129°. Ptolemy's geography estimated the Chinese coast at the longitude of the Carolinas. So Columbus started west on an uncertain expedition, and, believing Behaim, with whom he had been associated at Lisbon, 1480–84, concluded that in reaching land he had found Cathay. He caused the whole crews of his squadron (about eighty sailors) to swear that they *believed* he might go from Antilia (Cuba) to Spain by land, keeping west. Having letters from the Catholic monarchs to the Great Mogul Khan in Cathay, he sent on shore a baptized Jew who was acquainted with some of the Oriental languages, but his messenger failed to make connection. Columbus died before the error was discovered; he named the natives "Indians," and so much of the matter remains to this day. See MAP; where the globes of Behaim and Schöner are compared with the previous maps of Ptolemy, Strabo, Hecatæus, and others.

"Then to Moxon's, and bought there a payre of globes; cost me £3 10*s*."— PEPYS, 1663.

In the history of globe-making, the name of Ferguson, the mathematician, has an honorable place.

Modern globes are made of paper and plaster, are

Digitized by Google

perfectly balanced on their axes, and are proof against changes of temperature.

The first thing is a wooden mold, which is of a spherical form, and has two axial pins at its poles. This is placed in a frame, and, as it revolves, is covered over with wetted strips of strong paper. This is covered with successive thicknesses of pasted brown and white paper, laid in strips. The mold, with its paper covering, is then dried. Being dry, it is mounted in a frame on the axial pins, and the paper envelope is cut in two equatorially. The hemispheres are removed from the mold and are nailed to the ends of a central wooden rod, in whose ends are pins which project from each pole. The rod and pins form the axis. The hemispheres are joined at their edges by glue.

The shell is then placed on its axis in a frame and revolved as a compound of whiting, glue, and oil is plastered upon it. A semicircular scraper removes the redundancy and insures the spherical form. This coating is repeated four or five times, being dried between each coat. The sphere is then polished; then balanced by letting in shot in certain places to remove any want of equipoise.

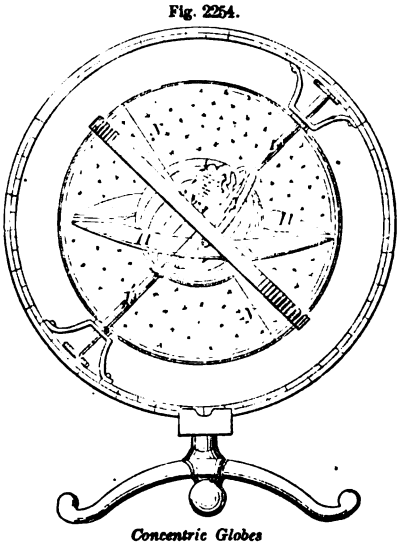
The parallels and meridians are now drawn on the globe by a beam-compass, to serve as guides for placing the engraved strips. These are fourteen distinct pieces. The arctic and antarctic circles are two circular pieces, and the other twelve are for the other portions, six on each side of the equator. The pieces of paper are thin, tough, and wet, and are rubbed down upon the globe, spreading them so as to make their edges exactly coincide with the lines on the globe. The globe is then colored according to geographical divisions, varnished and mounted.

A slate globe has lately been invented, having the meridians and parallels of latitude marked upon it, to be filled in by pupils as a geographical study. It is a powdered slate surface placed on the paper shell. A globe has been made in papier-maché, divided into forty-eight pieces, to be taken apart and put together at pleasure; the object being to facilitate package and removal, and the convenient study of any one part. Another novelty is a globe made of tissue-paper and inflated with air; such a globe may be made twelve feet in diameter, and is useful in a lecture or school room. A very cheap paper globe is now met with, in which the printed gores are brought together edge to edge by a string, not exactly to a spherical form, but sufficiently so for familiar reference.

Globes are also made by Goodyear, of inflated india-rubber, or of silk coated with india-rubber solution. Adams has made them of gutta-percha, with surface in relief, and in detachable zones and sections.

Globes of paper pulp have been suggested, molded inside of shells whose inner surfaces have intaglio representations of the inequalities of the earth's surface, so that the globe shall represent the mountains and valleys. It would be necessary to exaggerate the altitudes to make them visible. A model earth twenty-one feet diameter gives us only one thirty-second of an inch to a mile; on such a globe, one-hundred-acre farms would of course be utterly invisible to the naked eye, and the loftiest ranges of mountains might be represented by a few grains of rifle powder; and the entire human family, estimated at one thousand millions, might be gathered, without uncomfortable crowding, upon a spot less than one twelfth of a superficial inch. The greatest depths which man has yet been able to reach, in the way of mining or otherwise, would not exceed the thickness of thin card-board, and the entire animal portion of the earth now living would scarcely fill a child's thimble. The extent of the sensible atmosphere would not exceed one inch and a quarter; and if man shall ever be able to penetrate the earth to the depth of ten miles, it would be but little more than a quarter of an inch on this 21-feet

Fig. 2254.



Concentric Globes

model; hence the model earth must be many times 21 feet in diameter in order to show to the naked eye any of the great works of mankind on a like scale.

Rigaud used the paper surface of a 36-inch globe to estimate the relative quantities of land and water. Carefully cutting the land and water apart with scissors, he weighed the two in a delicate balance, and found it, water 734, land 266.

Fig. 2254 represents a concentric arrangement of a terrestrial globe, and a transparent celestial globe with the constellations on the surface of two hollow hemispheres, which have also the line of the ecliptic *N*, and the solstitial and equinoctial colures. The universal horizon *H* is suspended from the forked arms *I* of the axis *D*. The line of the junction of the hemispheres marks the celestial equator. Ziebermayer's globe is of glass, with a glass shell marked with the constellations.

Globe-clock. A globe so mounted as to revolve once in twenty-four or twelve hours, as the case may be, so as to indicate the time on any meridian by an hour circle, or the noon at the time of observation by means of the meridian circle. In the example, the works of the chronometer are in the interior, and are wound up by the lower arbor *F*; these works turn the globe, the axis

Fig. 2255.

Globe-Clock.

Digitized by Google

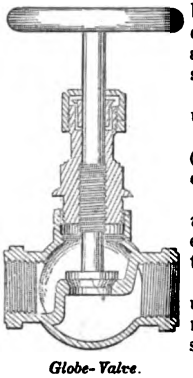
of the daily wheel of the chronometer being coincident with the axis *F*. *d* and *b* are hour and minute hands, which move around over the dial *D*.

Globe-cock. Formerly a sphere with a stem by which it was moved towards and from its seat; now a circular disk of similar use, and retaining the name, although but a zonal segment of a sphere is used. See GLOBE-VALVE.

Globe-fil'ter. A filter having a chamber of spherical form, whose hollow interior has a perforated diaphragm or a body of filtering material.

Globe-valve. 1. A ball-valve; one of a spherical shape, usually operated by a screw stem. The valve is now but seldom spherical, but is a disk or frustum of a cone fitting against a seat of corresponding shape, as in the figure.

Fig. 2256.



Globe-Valve.

2. A valve inclosed in a globular chamber.

Gloom; Gloom-stove. (*Gunpowder Manufacture.*) The drying-oven.

Glo'ry-hole. (*Glass-making.*) An opening in the wall, exposing the brilliant white of the interior of a glass-furnace.

Gloss'ing. An operation upon silk thread by which it is moistened with steam and stretched to develop a gloss.

Glos'so-co'mon. A form of winch with gear-wheels and pinions, and used for raising heavy weights.

Glost-ov'en. (*Porcelain.*) An oven in which glazed ware is fired.

Glove. 1. A covering for the hand (A. S. *glof*; Ger. *Handschuh*) differing from the mitten in having a separate compartment for each finger.

Gloves are made from a great variety of materials, as textile fabrics of cotton, linen, wool, silk, the pelts of the thinner-skinned animals, india-rubber, etc.; and in former ages steel, arranged in the form of plates or rings to afford flexibility, was employed for the gloves or gauntlets of the mailed warrior.

The skins principally employed for the finer kinds of gloves are those of the kid and goat, but other kinds of fine and flexible leather are also used. It has been asserted that large numbers of "kid" gloves were made from the skins of rats caught in the catacombs and sewers of Paris, but this assertion does not appear to be warranted by fact.

Great quantities of kid gloves are now made in this country, the process of manufacture, beginning with preparing the skins, being as follows.

In dressing kid or goat skins for gloves they are first soaked in water and "fleshed," and are then thrown into the vats of lime-liquor, where they remain from three to six weeks, being occasionally moved and turned until the hair is sufficiently loosened. They are then stretched upon the *beam*, and the hair removed with the blunt drawing-knife, carefully preserving the grain. They are next put into a *drench* of bran and water, or, more properly, moistened bran, where they remain for a considerable time. This softens and renders the skin very pliable. On being removed from this, the *tawing* process, which is a substitute for tanning with bark, takes place. The skins are covered by a mixture of salt and alum, which makes leather of them. After being cleansed and dried they are ready for the finishing processes. They are suspended and *staked*, that is, evened by a blunt knife drawn over the surface. Afterwards they are spread out upon a flat surface and rubbed with a sponge dipped in the beaten yolk of eggs. This preparation is absorbed by the leather and serves to make it elastic.

The next and last process is coloring. Liquid dyes are used for this purpose, and they are applied to the surface or grain of the leather with a brush. After all the processes of trimming, finishing, and dyeing are completed, the skin is stretched upon a marble table and rubbed with a blunt knife. It is then cut through the middle, and a strip for the palm and back of a glove cut, just wide enough for the purpose, from one end of each piece. Being cut in this way the pairs are alike, of similar finish, thickness, and tint. In some factories gloves are cut in part by punches of steel, which have teeth that prick the holes for the stitches. The seams are then sewed by laying the edges evenly together and placing them in a vise provided with teeth one twelfth of an inch apart, between which teeth the needle passes in sewing. After the seams are sewed the embroidery is put upon the back, the wrist bound or otherwise finished, and the fastenings sewed on. The glove is next stretched, placed in a linen cloth slightly dampened, and beaten to make it more flexible. It is then pressed, and is ready for the market.

By a slightly different mode of operation, after being assorted as to quality and size the skins are transferred to the cutter, who cuts them into oblong pieces of the required size, which are turned over to the puncher, who takes two or three pairs at a time and subjects them to the action of a press carrying a punch corresponding to the size of glove to be made, which forms the hand with all the necessary slits, openings, button-holes, gussets, etc. The thumbs and *fourchettes*, or pieces between the fingers, are punched separately. Any roughness of the edges is removed by the scissors. After undergoing final inspection to detect defective pieces they are sent out to the sewers, and on their return are "topped," the buttons sewed on, and button-holes completed.

They are then "dressed" or straightened, stamped with the maker's name, and packed.

In Europe the skins of the young kid, roughly dried in the open air, are collected by peddlers who, setting out from Italy in the early spring, extend their peregrinations to the northern confines of the continent as the season advances and the young kids attain a sufficient degree of maturity. By the peddlers the skins are sold to traders in the larger towns, whence they find their way to the great marts for such articles, as Naples and Leipsic.

The method of treating the skins is essentially the same as that adopted in this country. Some of the French manufacturers tan and dye the skins themselves, so as to insure uniformity in color and quality, while others are content to buy them ready prepared.

The dye is applied to the outer surface of the leather only by means of the hands and the assistance of a brush, and does not penetrate beyond the exterior. The best skins are colored black and other dark tints, holes or other imperfections showing more plainly in these than in lighter colors, so that the poorer kinds are used for white and other light shades. The variety of tints is about two hundred.

There are ten different sizes, from 5¼ to 8, for ladies' gloves; thirteen, from 7½ to 11, for gentlemen; and seven, from 5 to 6¼, for misses. Each of these sizes has a corresponding plate which serves as a guide to the cutter.

Buckskin or deerskin gloves also form an important article of manufacture. The skins are derived

Digitized by Google

from various parts of the North American continent, from South America, and a few from Europe and Asia. After being limed, fleshed, and unhaired, they are treated with oil in a stamping or pounding mill; the oil is removed by means of soda-ash, with which it forms a soap that is washed out. The skins are then stretched and suppled by rubbing with a stretcher iron or *stake*, colored with a wash of ocher, and their surfaces smoothed by grinding on a wheel covered with emery and pumice.

The gloves are cut out with steel dies, and stitched by a machine. When finished, they are dampened, stretched upon a hand-shaped board, dried and packed for transportation.

Fur gloves are made with the inner portion or palm of kid or dog skin, and the back of fur. They are lined with flannel or an inferior quality of fur, usually the white squirrel or coney or lamb-skin with the wool on, and are used in winter traveling, driving, etc.

India-rubber gloves are intended for the use of manufacturing chemists, druggists, and photographers, or all who work among acids, alkalies, and other caustic materials. They are also adapted to the use of firemen, hatters, tanners, and dyers.

In the manufacture of india-rubber gloves, the first process is to heat slightly a mass of the gum, which is rolled into a flat sheet between revolving cylinders. From this sheet the gloves and mittens are cut by gouges similar to those employed in the cutting of leather gloves. They are then joined by placing the edges in contact, and covering them with strips of heated rubber.

A lighter style is made thus: A piece of cotton cloth or stockinet is passed through the cylinders at the same time with the gum, which by this process completely coats it. From this the gloves are cut, and joined by covering the edges with strips of heated rubber. These gloves are made of a variety of colors, are very soft and pliable, and have a very neat finish. Gloves are made with corrugated rubber palms for use in washing.

Pliny recommends the use of gloves and boots to those engaged in pulling spartium, — a variety of the broom, and used, when soaked and broken like hemp, to make coarse cordage and the commonest description of garments. He also recommended them to his secretary, that he might not be impeded by chilly fingers in noting down memoranda.

Xenophon ridicules the effeminacy of the glove-wearing Persians. (*Cyrop.* VIII. 8, 17.) They do not appear to have been worn by the ancient Egyptians, but were regarded as a part of the indicative dress of Northern barbarians.

Some dirty-handed cynics calling themselves philosophers railed at the Roman gentry for wearing gloves.

The father of Ulysses wore gloves while working in his garden. So said Homer.

The use of gloves in common life is a habit of late introduction.

During the Middle Ages the glove was worn as a badge of distinction, and also in the helmet as a token of a lady's favor. See Hall's "Chronicle," time of Henry IV.

Charlemagne recognizes in a grant the use of leather in making gloves and book-covers. Ethelred II. had a present of two pairs from a merchant company. Henry II., when he lay in state, was habited in gloves. Elizabeth wore embroidered gloves, and is thus painted: —

"Painted leather gloves, very pretty and all the mode." — PEPYS, 1663.

2. (*Hat-making.*) A smooth piece of wood for rubbing a sheet of felt, and causing the nap to adhere to the body when working at the *battery*. The *glove* is held in the palm of the hand and tied on by a string.

Glove-mak'ing Ma-chine'. The apparatus upon which gloves are stitched consists essentially of a pair of jaws opened and closed by means of a treadle, and having at their holding edges teeth between which the needle is passed back and forth in sewing, thus regulating the length of stitch. The cutting apparatus has a reciprocating head provided with movable dies of various sizes.

Glue. Glue is made of the clippings of hides, horns, and hoofs; washed in lime-water, boiled, skimmed, strained, evaporated, cooled in molds, cut into slices, and dried upon nets.

It is principally prepared from the parings and waste pieces of skins, the refuse of tanneries, and the tendons and other offal of slaughter-houses. These are steeped in milk of lime for about two weeks and afterward dried. In this state they may be preserved for an indefinite length of time. Previous to boiling they are again steeped in weak milk of lime for from twenty-four to thirty hours, and then placed in a boiler having a perforated false bottom to prevent burning. (See GLUE-BOILER.) Here the scraps are gently boiled until a firm gelatinous liquid is produced, the clear portion of which is run off into another vessel, and a small quantity of dissolved alum added thereto. Here it is kept hot by means of a water-bath, and allowed to remain for several hours in order to deposit its impurities, after which it is run into the congealing boxes and placed in a cool situation.

On the next day the sheets thus formed are turned out upon wetted boards and cut into cakes, by means of a stretched brass wire, which cakes are farther subdivided by a moistened flat knife, and placed on nettings to dry.

They are, after drying, dipped into hot water and slightly rubbed with a brush wetted with boiling water to give them a gloss, and stove-dried. This furnishes the palest and best glue.

The residuum left in the boiler is treated with fresh water, producing an inferior article of glue, and this operation is repeated again and again, so long as any gelatinous matter can be extracted from the scraps.

Glue was used by the cabinet-makers of ancient Egypt.

The Greeks used various sticky matters, such as glue, bird-lime, and cobblers' wax.

"Wood is joined together with glue, prepared from certain parts of oxen, and with such strength that the veins of boards will open in a crack, sooner than the seams of ox-glue will relax their fastenings." — LUCRETIUS, Book VI.

Isinglass glue; soak isinglass in cold water; when swelled, put in spirits of wine; heat it in a bottle plunged in a bath; add powdered chalk.

Gelatine glue; swell in cold water; immerse in linseed-oil and heat in a bath; add red lead.

Water-proof glue; boil two ounces of isinglass in a pint of skim-milk, until the required consistence is obtained.

Marine glue; shellac and caoutchouc, equal parts, dissolved in separate portions of naphtha, and then mixed.

Or, india-rubber, 1 pound; coal naphtha, 4 gallons; shellac, 2 ounces.

White fish-glue, or *diamond cement*, is made of isinglass dissolved in alcohol.

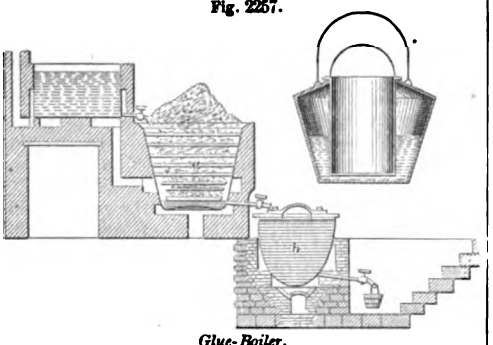
Spalding's liquid glue; glue and acetic acid.

Glue-boil'er. A convenient apparatus for boil-

Digitized by Google

ing skins into glue has three coppers, at different hights; the upper, acted on by the waste heat from the chimney, warms the water, which is then drawn off into the central one (*a*) in which the scraps are placed, and which has a perforated false bottom, and the third (*b*) receives the gelatinous solution

Fig. 2257.



Glue-Boiler.

obtained by boiling. The last vessel is double, with water between the inner and outer shells, and discharges its contents into buckets, by which the solution is transferred to the evaporating-boxes.

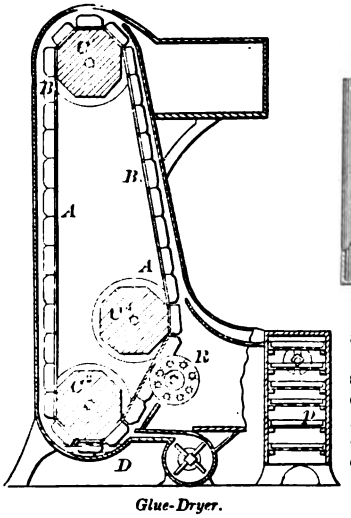
Above is shown a carpenter's glue-pot.

Glue-can. A kind of glue-pot in which the prepared glue is kept in the inner can, and it is surrounded by an outer tin vessel containing water for heating the glue.

Glue-ce-ment'. To resist moisture. Glue, 4 parts; black rosin, 4 parts; red ochre, 1 part. Or, glue, 4 parts; boiled oil, 1 part; oxide of iron, 1 part.

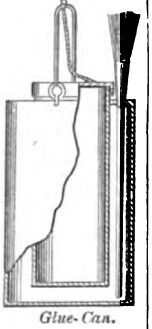
Glue-dry'er. A machine or closet for drying

Fig. 2258.



Glue-Dryer.

Fig. 2259.

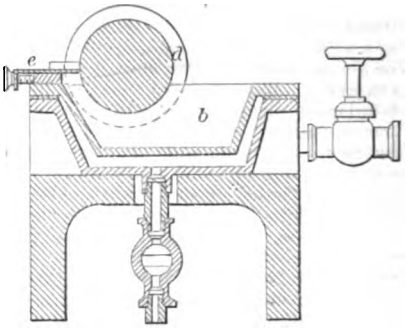


Glue-Can.

sheets of glue. In the example, the endless web *A* *B* has sections of plates which dip at their lowest position into the depression *D*, which contains liquid glue. As the octagonal roller C^1 C^2 rotates, the glue-covered plates ascend, being accompanied by a blast of heated and dry air from the blower below. An additional or intermediate pulley or drum C^3 is arranged between the two supporting pulleys, to deflect the endless chain and its plates against rotating disks carrying brushes *R*, which latter remove the glue from the plates. During their descending motion, the plates are exposed to air chemically dried in the furnace *p*.

Glue'ing-ma-chine'. One for smearing upon an applied surface a thin and even coating of liquid glue. In the example, *b* is a tank of glue kept

Fig. 2260.

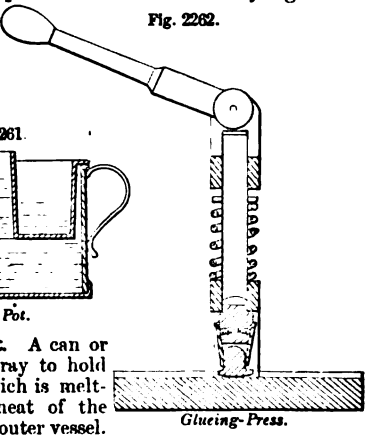


Glueing-Machine.

heated by a steam-jacket. *d* is a roller, whose lower portion revolves in the tank; a scraper *e* removes the redundancy, and its upper surface is coated with a thin pellicle, suitable for application to a leather strip which is to be joined to its fellow, or a veneer which is to be attached to an object.

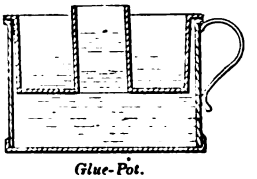
Glue'ing-press. One to hold firmly together a number of parts which have been attached by glue or cement.

Fig. 2262.



Glueing-Press.

Fig 2261.



Glue-Pot.

Glue-pot. A can or pot with a tray to hold the glue, which is melted by the heat of the water in the outer vessel.

Glut. 1. A wooden wedge used as a quoin, a chock in splitting timber, or as a fulcrum to a lever.

2. (*Nautical.*) *a.* A patch at the center of the head of a sail, having an eyelet for the becket-rope.

b. A choking, as by throwing the fall of a rope across the sheaves.

3. (*Bricklaying.*) A small brick or block introduced into a course to complete it.

Glyc'er-ine. A viscid, colorless liquid, having a sweetish taste but no odor, which may be derived from nearly all oily or fatty substances. It was discovered by Scheele in 1779. Its chemical combination is $C_6 H_8 O_6$. It unites readily with water, and the combination thus formed, as well as pure glycerine, is capable of solving a great variety of substances. Upon this circumstance, its non-liability to freeze at low temperatures, its slight volatility at temperatures below 200° F., and its efficacy as a preservative agent, its value in the arts chiefly depends. Glycerine is obtained by various processes, the object being to detach it from its combination

Digitized by Google

with the acids, oleic, margaric, and stearic, to which it is united as a base. The refuse from soap-making contains a large proportion of it, which has been usually thrown away.

It may be obtained by treating olive-oil with oxide of lead, leaving a residuum of impure glycerine, which may be purified by sulphuretted hydrogen, and concentrated by evaporation over a water-bath.

The preferable process is by passing steam, heated to between 500 – 600° Fah., through a fatty substance in a still. The glycerine and fatty acids distill over, are separately condensed, and may be concentrated by evaporation. The purity depends upon that of the substance employed.

Glycerine is employed in medicine as a vehicle for liniments, carbolic acid, etc., and may be used for forming extracts and tinctures. It is also employed in soaps and cosmetics of various kinds, imparting a sense of moisture and coolness to the surfaces where applied; and for preserving animal and vegetable preparations, not shrinking them as alcohol does. Its non-evaporability makes it useful as an ingredient in copying-ink, and by treatment with nitric acid it forms the well-known explosive nitro-glycerine.

Glyph. (*Architecture.*) Perpendicular fluting, used in the Doric frieze.

Glyph'o-graph. A name given by Mr. Palmer to his system of relief line-engraving.

A thin ground of wax is spread upon the plate; this is etched or cut away so as to give the design in intaglio. The ground is now covered with a film of graphite, after which metal is precipitated upon the metal in an electro-bath, giving a metallic plate with the design in relief. The copper shell is backed with lead and used as an ordinary printing surface. By a similar process the engravings which illustrate this book have been made. See RELIEF LINE-ENGRAVING.

Glyp'to-graph. An engraving on a gem or a semi-precious stone.

Gno'mon. 1. *a.* The style, or pin, which, by its shadow on the dial-plate, shows the hour of the day. See DIAL.

b. A roll or pillar, from whose shadow the altitude of the sun may be determined. Such were in use in ancient Egypt, in China, and such were found at Quito by the invading Spaniards.

The astronomer Uleg Beg erected a *gnomon* at Samarcand in 1437, the hight of which was 176.89 feet. The gnomon of the sun-dial of Delhi takes the form of an elevated staircase. See DIAL.

The *gnomon* or *style* of a horizontal dial has an edge parallel to the axis of the earth, and makes with the horizontal plane of the dial-plate an angle equal to the latitude of the place.

The gnomon was anciently used in China for astronomical purposes, but this people did not excel in dialing. A measurement of the length of the solstitial shadow, made by Tschen-Kung, at Loyang, on the Yellow River, 1200 B. C., was found by Laplace (quoted by Humboldt in "Cosmos," Vol. II. p. 115) to accord perfectly with the present accepted theory of the change in the obliquity of the ecliptic.

"The sun-dial and the gnomon, with the division of the day into twelve parts, were received by the Greeks from the Babylonians." — HERODOTUS, II. 109.

Eubulus, the comic poet, quoted by Athenæus, who wrote about A. D. 220, says: —

> "We have invited two unequalled men,
> Philo-crates and eke Philocrates, —
> For that one man I always count as two,
> I don't know that I might not e'en say three.
> They say that once when he was asked to dinner,
> To come when first the dial gave a shade
> Of twenty feet, he with the lark uprose,
> Measuring the shadow of the morning sun,
> Which gave a shade of twenty feet and two.
> Off to his host he went, and pardon begged
> For having been detained by business;
> A man who came at daybreak to his dinner!"

The gnomons of Peru disgusted the invading Spanish, who, of course, had never bowed to images One obelisk at Quito was in the center of a circle, on which was marked an east and west line indicating the equinox. The ruthless conquerors thought it was an idol, and did not comprehend that they were on the equator. The men who were expelled from Cordova about 290 years previous could have explained the use of the pillar. See DIAL.

2. An instrument, more employed formerly than now, for measuring altitudes and declinations of the sun and stars. It was usually a column erected upon level ground or pavement. An observation made at Marseilles by Pytheas in the time of Alexander the Great showed that the gnomon at that place was as the meridian shadow at the summer solstice, as 213½ to 600.

Cassini's celebrated gnomon in the Church of St. Petronius at Bologna was eighty-three French feet in hight.

Goaf. (*Mining.*) An excavated space from which the ore has been removed. It is sometimes made the receptacle for the *deads* and *attle* of the mine to avoid sending them up to the surface, and to support the roofs of the workings.

Gob; Gobb. (*Mining.*) *a.* A *goaf* or abandoned working in a mine from which the ore or coal has been taken, and is now used to contain refuse.

b. Attle, waste, rubbish of working. *Gobbing.*

Gob'e-lins. (*Fabric.*) A superior kind of French tapestry, deriving its name from the brothers Gobelin, the first manufacturers.

Go-cart. A small frame, without a bottom and running on casters, for teaching infants to walk.

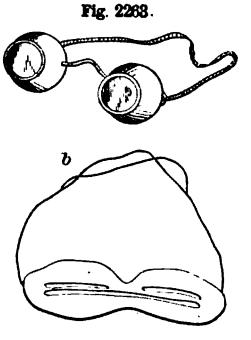
Gof'fer-ing-ma-chine'. A machine for making plaits or ruffles. See GAUFFERING-MACHINE.

Gog'gles. 1. Eye-blinds for horses.

2. Tubes or glazed cases in front of the eyes for protection from dust or intense light.

A similar arrangement for weak eyes was used by Pepys, and described by him in his "Diary" of April 25, 1669, under the name of a vizard "with tubes and glasses got to put in and out. I paid him 15 *s.*"

Fig. 2263.



Goggles.

Wooden goggles (*b*) are worn by the Yukon Indians of Alaska. They are used to diminish the light and prevent the glare from producing blindness. This mode of contracting the diaphragm resembles, except in not being automatic, the device in the eye of a cat, the iris of this animal diminishing by lateral contraction instead of orbital. See IRIS-DIAPHRAGM.

Go'ing-bar'rel. (*Horology.*) *a.* A barrel containing a mainspring and having a cog-wheel on its periphery which drives the train. It supersedes the arrangement of chain and fusee.

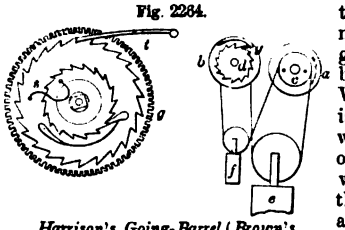
b. A ratchet-wheel with pawl and spring on the shaft of the great wheel, by which the works are

Digitized by Google

kept going while the clock is being wound up. Invented by the celebrated English watchmaker, Harrison.

In this, the larger ratchet-wheel, to which the click *t* is attached, is connected to the great wheel *g* by a spring *s*. While the clock is going, the weight acts upon the great wheel *g* through the spring; but as soon as the weight is taken off by winding, the click *t*, whose pivot is set in the frame, prevents the larger ratchet from falling back, and so the spring *s* still drives the clock-wheel during the time the clock takes to wind.

Fig. 2264.



Harrison's Going-Barrel (Brown's Mechanical Movements).

A modification of the device was adapted by the same inventor to suit watches.

Go'ing-wheel. An arrangement invented by Huyghens to keep a clock in motion while winding. In Fig. 2264, *a* is the going and *b* the striking wheel, carrying on their axes the pulleys *c d*, which, by means of an endless cord or chain, sustain the pulleys carrying the weights *e f*, the latter serving merely to keep the chain taut; each of the pulleys *c d* supports half the larger weight, so that on turning the pulley *d*, in the act of winding, the weight *e* while being raised still continues to act with half its force on the pulley *c*, the pulley *d* turning so as to lift the weight *e*, and being prevented from going back by the engagement of the pawl *g* with its toothed exterior.

Gold. Equivalent, 98.7; symbol, Au. (Aurum); specific gravity, 19.2; point of fusion, 2282° F. Found in the native state, mechanically associated with earths and sometimes alloyed with metals. It is a heavy, yellow, lustrous, malleable, ductile, non-oxidizable, soft metal. Its uses are for coin, plate, ornaments, and articles of luxury.

Its principal sources are California, Australia, the western coast of Africa, and the Ural. It is a very widely disseminated metal, but is only found in paying quantities in a few countries. Wicklow, in Ireland, parts of Nova Scotia and of Virginia and North Carolina, yield this metal.

The principal supplies of gold in the land of Egypt were derived from the gold mines in the desert of the Upper Country. Their position, according to Wilkinson, is still known to the Arabs, and is about southeast from Bahâyreh, a village opposite the town of Edfou, at a distance of ten days' journey. The gold lies in veins of quartz in the rocks bordering an inhospitable valley and its adjacent ravines, and yields a small quantity in proportion to the labor required. Water is scarce, the locality is remote from food and the materials necessary for the prosecution of the work, and do not seem to offer any prospect of reward for reopening.

They were run by slave power at a time when the sacrifice of human life by hardship was a matter of little concern; as was evinced in other regal undertakings, — the building of the Pyramids, the quarrying, moving, and erection of the monoliths, and the digging of the canal from the Nile to the Red Sea.

Agatharcides states that the toil of extracting the gold of these mines was immense. The rock was pounded fine, and the gold was separated by frequent washings, and the account is confirmed by paintings on the tombs executed in the reign of Osirtasen, about 1740 B. C.

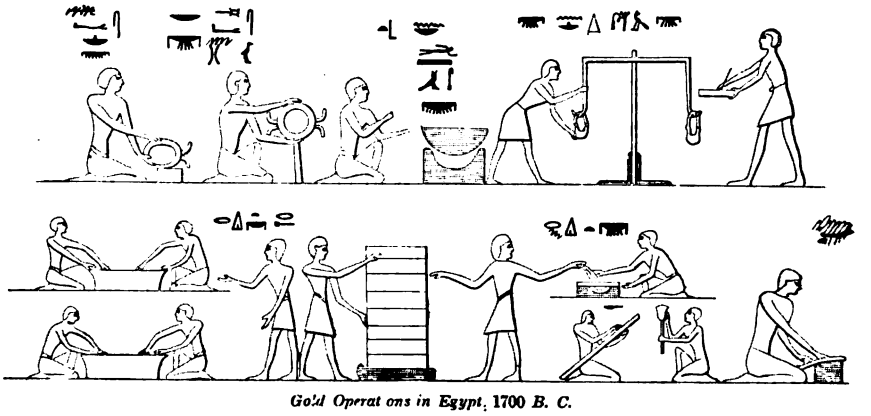
Mehemet Ali announced his intention to reopen these mines, but desisted. He was tyrant enough for the purpose, but had a method in his madness, and was doubtless deterred by mechanical and climatic difficulties. The skeletons of the victims of his rapacity in Egypt would have paved the road across the desert to the desolate hills devoted to the *auri sacra fames*.

These mines are said to have yielded $35,000,000 per annum in the times of Rameses II., fourteenth century B. C., and were still worked under the Ptolemies.

The "*molten* calf" and the fact that Aaron "fashioned it with a graving tool" show that casting and engraving metals were known 1490 B. C., and the character of the articles found in the tombs, as well as the paintings and sculptures, point in the same direction. A curious series of pictures at Beni-Hassan point out with some clearness the process of collecting and working gold. (Fig. 2265.)

Reference has just been made to the account of Agatharcides, where he describes the hardships of the gold-miners. A fuller description is given of it by Diodorus, entering into a detailed statement of the cruel treatment of the unfortunate convicts who were sent by thousands to the spot and worked under the lash without any alleviation, care during sickness, or any hope except in death. The account

Fig 2265.



Gold Operations in Egypt, 1700 B. C.

Digitized by Google

is too long to insert, but stands along with the history of Spanish operations in the gold mines of Hispaniola as an example of what can be done by men who "neither fear God nor regard man."

The illustration is taken from a tomb at Beni-Hassan, and includes the operations from the washing of the pounded ore to the making of jewelry.

The words of Diodorus, 10 B. C., throw much light on the process employed in his time. He states that the "marble shining rock" (quartz) is excavated by main force by iron picks and chisels, and carried by boys from the bottom of the shafts to the open air. It is then pounded by iron pestles in stone mortars till the pieces are reduced to the size of a lentil. It is then ground in the ordinary hand mill to a fine powder. He then proceeds to say: "At length the masters take the stone thus ground to powder and carry it away to undergo the final process. They spread it upon a broad table a little inclined, and, pouring water upon it, rub the pulverized stone until all the earthy matter is separated, which, flowing away with the water, leaves the heavier particles behind on the board. This operation is often repeated, the stone being rubbed lightly with the hand; they then draw up the useless and earthy substances with fine sponges, gently applied, until the gold comes out quite pure. Other workmen then take it away by weight and measure, and putting it with a fixed proportion of lead, salt, a little tin, and barley bran, into earthen crucibles well closed with clay, leave it in a furnace for five successive days and nights, when it is suffered to cool. The crucibles are then opened, and nothing is found in them but the pure gold, a little diminished in quantity. Such is the method of extracting gold on the confines of Egypt, the result of so many and such great toils. Nature indeed, I think, teaches that as gold is obtained with immense labor, so it is kept with difficulty, creating great anxiety, and attended in its use both with pleasure and grief."

The series of operations shown in the cut evidently refer to something similar to the process described by Diodorus. A man is spreading the auriferous mud on a board; then appears a man with a shovel, and another with an inclined chute. A fourth is working with a pan, into which water is poured by a fifth person. The latter also throws water into a riffle, which is a series of steps. Others are washing and stirring the material in pans. Next we see the scribe and the scales. Then the crucible, presided over by a man with a blow-pipe; and as a sequence are jewelers making up the gold into an ornamental form, for some purpose not apparent to the writer, though no doubt clear enough to the artist of thirty-five centuries ago.

Gold was first coined in England in A. D. 1257. The amount of gold that passed through the English mint from 1558 (accession of Queen Elizabeth) to January 1, 1840, is 3,553,561 pounds' weight, troy. The value of gold coined in the reign of George III. was £74,501,586.

An ounce of gold will cover a silver wire 1300 miles in length, and a grain of gold may be extended into a leaf of 56 square inches. Gold-leaf may be reduced to the 290,000th part of an inch. See AMALGAMATOR; GOLD-LEAF.

Gold-al-loys'. Those in which other metals are added to gold to confer hardness, as in coin, or to cheapen the product, as in some jewelers' alloys and solders. See ALLOYS, pp. 62, 63.

Gold-beat'er's Ham'mer. A hammer with two somewhat rounded faces, used in beating the pack of alternate gold ribbon and vellum or gold-leaf and skin. As the work progresses smaller hammers are used.

The *forging-hammer* is used in reducing the ingot of gold to one sixth of an inch thickness. The anvil is a steel block 4 × 3 inches on the face.

The hammer for the first course of beating is short handled and weighs 15 or 16 pounds. The hammer for the next beating weighs 10 pounds.

The French series of hammers is:—

The *flat* or *enlarging hammer*. Its head is slightly convex, and has a diameter of 5 inches. Its shape is a truncated hexagonal pyramid, the face being the base. It weighs 14 or 15 pounds.

The *commencing-hammer* is more convex than the flat, has a face of 4 inches, and weighs 6 or 7 pounds.

The *spreading-hammer* (*marteau à chasser*) is still more convex, has a head 2 inches in diameter, and weighs 4 or 5 pounds.

The *finishing-hammer* is still more convex, has a face 4 inches in diameter, and weighs 12 or 13 pounds.

Gold was beaten into thin sheets by the ancient Egyptians, and used in ornamenting furniture, coffins, and numerous other articles.

Gold-beat'er's Skin. Prepared from the peritoneal membrane of the cæcum of the ox. Used to separate the leaves of gold while under the hammer.

Gold-beat'ing. See GOLD-LEAF.

Gold-block'ing. Pressure of an engraved or composed block upon gold-leaf spread upon a book-cover. Without the leaf it is called *blind-blocking*.

Gold, Chlo'ri-na'tion of. See CHLORINATION.

Gold-fur'nace. This resembles a brass-furnace (see BRASS-FURNACE), but is usually built above the floor, occupying one side or more of the shop, and appearing like a stunted wall. The aperture for the fuel and crucible in each furnace is 9 to 16 inches square, and 11 to 20 inches deep. The front edge of the wall is horizontal and stands about thirty inches from the floor, but the top inclines backward at an angle of about 30°, and a ledge holds the *tiles* which close the tops of the furnaces.

The crucibles are usually of black-lead.

The auriferous copper ore of Colorado is thus reduced. The pyrites are roasted in kilns, wood being the fuel, expelling about half the sulphur. The black mass, protosulphide of iron, is calcined in brick ovens, being stirred with iron rods. The resulting black or brown powder is placed on the hearth of a reverberatory smelting-furnace, with such mixture of auriferous, argentiferous, and cupriferous ores as shall produce the reactions which will separate the materials into a floating dross and a pool of metal. The ferruginous slag is drawn off at an upper hole, and a mixture of gold, silver, copper, and iron at a lower hole, forming a *matt* which is shipped to Swansea, Wales, for complete separation.

Gold, Im-i-ta'tion. *Mock-gold.* See JEWELER'S ALLOYS, p. 63.

Gold-leaf. Gold-leaf was made in Egypt 1706 B. C. Homer refers to it. The temple of Solomon was profusely gilt. Pliny states that in his time a single ounce admitted of being beaten out into 750 leaves, four fingers in length by the same in breadth. This tenuity is very far exceeded at the present day. In the practice of the art in Europe, the skin of an unborn calf was first used; afterwards a fine pellicle from the entrails of cattle. This continues to be used (see *supra*). "About 1621," says Beckmann, "Merunne excited general astonishment, when he showed that the Parisian gold-beaters could beat an ounce of gold into 1,600 leaves, which together covered a surface of 105 square feet. But in 1711, when the pellicles discovered by the Germans came to be used in Paris, Réumer

Digitized by Google

found that an ounce of gold, in the form of a cube, 5½ lines at most in length, breadth, and thickness, and which covered a surface of about twenty-seven square lines, could be so extended by the gold-beaters as to cover a surface of more than 1466½ square feet."

The Egyptian mummy-cases were sometimes profusely gilded, and in some instances the body itself.

A small percentage of silver and copper is added to gold for beating, perhaps about 1½ per cent of alloy. The ingot is rolled into a *ribbon* by repeated passage between rollers, and this ribbon has a thickness of $\frac{1}{3\,0\,0}$, a surface of 500 square inches to an ounce of gold.

The gold-beater takes 800 pieces of the "skin," which is a tough, thin membrane from the intestines of an ox, and thus proceeds: A hundred and fifty bits of ribbon gold an inch square are interleaved with as many vellum leaves four inches square, forming a *cutch;* this pack is beaten for a long time with a ponderous hammer on a smooth marble slab until the gold has thinned and expanded to the size of the vellum. How the workman manages so as to beat all the pieces equally, and yet beat none into holes, he alone can answer; it is one of the mysteries of his craft. The gold is liberated from its vellum prison, and each piece cut into four; the hundred and fifty have thus become six hundred, and these are interleaved with six hundred pieces of gold-beater's skin, forming a pack called a *shoder*.

Another beating then takes place, more careful, more delicate, more precise than the former, until the gold, expanded as far as its envelope will admit, requires to be again released. The leaves are again divided into four, by which the six hundred become twenty-four hundred; these are divided into three parcels of eight hundred each, and known as *molds;* each parcel is subjected to a third beating. Heavy as the hammers are, there are yet degrees of heaviness; first, a 16-pounder for the *cutches*, then one from nine to twelve pounds for the *shoders*, and lastly a hammer of from six to seven pounds is employed.

Gold-min'ing. The different modes of collecting gold in the placers of California — and the same is true of some other places, Australia, for instance — are familiarly known as *panning*, *winnowing*, *cradle-rocking*, washing with the *long-tom* or the *quicksilver-machine*, *jamming* or turning the course of a river, *burrowing* or *tunneling*, *ground-sluicing*, *sluice-boxes* in connection with the *hydraulic process*, or water-jet. See list under METALLURGY; MINING.

In *panning*, the operator takes his station by the edge of the water, dips his pan, which he holds by the rim, and then imparts to it a rotary and oscillatory motion, occasionally stirring up the earth and mashing the clods. The large stones are thrown out and the water caused to circulate around the inside circumference of the pan, the heavier portions, including the gold, collecting in the center, and the lighter matters being discharged over the edge. The residue, consisting of fine gold and black sand, is separated after being dried.

The *winnowing* operation is practiced where water is not available, and consists of tossing in a blanket the finely powdered and dry earth, depending upon the wind to blow away the lighter particles.

The *cradle* is a box about 3½ feet long, 20 inches wide, and 18 inches deep. The top and one end are open. Upon the rear half of the top is fitted a box with a perforated sheet-iron bottom. This box receives the earth, which is disintegrated therein, and passes through the holes as the cradle is rocked to and fro. Water is bailed by hand from the stream, and the gold is arrested in its passage by wooden cleats placed on the inclined bottom of the cradle, while the lighter matters are carried out at the end by the stream of water. See CRADLE.

The *long-tom* consists of a shallow, inclined trough, from 10 to 20 feet long and perhaps 16 inches wide. At the lower end is an upwardly inclined perforated plate to arrest the gold which falls through the holes into a box below, while the tailings pass over the end by the force of the stream of water which is introduced into the upper end of the trough. The gold is collected by *riffles* in the box, and quicksilver is added to amalgamate the finer particles, if necessary.

The *quicksilver-machine* is somewhat similar to that last mentioned, but is intended to bring all the gold in contact with mercury, the amalgam being afterwards treated for the removal of the mercury. See AMALGAMATOR.

In *jamming*, the water of a river is turned into a temporary channel while the bed is explored for gold.

Burrowing or *tunneling* are adopted as a more economical means of reaching the lower strata or more valuable deposit upon the hard pan, or ancient river bottom, instead of digging away or working over the whole mass of superincumbent earth.

Ground-sluicing consists in turning a stream upon a bank of earth to remove it and uncover the more valuable strata below, the auriferous deposit in the upper portion being detained by its gravity to be washed with the lower denuded layer of *pay dirt*.

Hydraulic-mining by jet and sluice-boxes has given rise to some of the greatest engineering works of California. A series of boxes about 14 inches in length and 8 feet wide, called *sluice-boxes*, are fitted together at the ends so as to form a continuous trough, as long as may be desired, sometimes extending several thousand feet. The earth and stones are washed through this sluice by the force of a strong current of water, often brought from a great distance. The sluice has a flooring of wooden blocks which offer some impediment to the passage of the earth, and afford crannies for collecting the gold, and for holding the quicksilver by which the finer particles of gold are arrested and amalgamated. The bank of auriferous earth is washed into the sluice, thus prepared, by means of a powerful stream conducted through and directed by a pipe in the manner of a fire-engine. The water is brought to the scene of operations from immense distances, in some cases over one hundred miles, and the flumes and canals which form a network over the country are among the most remarkable local features (see FLUME). To quote from the description of "A Miner of 1849," Harper's Magazine, April, 1860: —

"To shovel a mass of several millions of tons of earth into this sluice for washing would be too expensive. By means of water directed through hose and pipe the labor of many men is cheaply performed, and the hill torn down to its base. The water is led through india-rubber or double canvas hose, and generally from a great hight above the scene of operations. It is consequently thrown with such force as to eat into the hillside as if the latter were sugar or salt. Several of these streams directed upon a hillside bring down more earth than could be thrown by one hundred men with picks and shovels. But the art of the miner does not rest here. He undermines as well as breaks down, working in a single cavern in the hillside with his water batteries until the earth topples over like an avalanche." See HYDRAULIC-NOZZLE.

By a combination of shovels and the current of

Digitized by Google

water the earth is then carried into the sluice in which it is disintegrated and washed down with great rapidity, the gold catching, as has been observed, in the interstices between the blocks which form the floor of the sluice. See AMALGAMATOR.

Gold-pen. A pen with a gold *nib* pointed with rhodium or iridium.

In 1823, Hawkins and Mordan (English) made tortoise-shell and horn nibs with diamond and ruby points. These were followed by plates of gold attached to the tortoise-shell nibs.

Doughty's pens were of gold with ruby points.

Wollaston's pens were of two flat strips of gold tipped with rhodium.

In 1851, the Birmingham Exhibition in London showed gold, palladium, and silver pens tipped with iridium and osmium.

Gold pens are now usually tipped with iridium, making what are commonly known as *diamond points*. The iridium for this purpose is found in small grains in platinum, slightly alloyed with this latter metal. The gold for pens is alloyed with silver to about sixteen carats fineness, rolled into thin strips, from which the blanks are struck. The under side of the point is notched by a small circular saw to receive the iridium point, which is selected with the aid of a microscope. A flux of borax and a blow-pipe secure it to its place. The point is then ground on a copper wheel with emery. The pen-blank is next rolled to the requisite thinness by means of rollers especially adapted to the purpose, and tempered by blows from a hammer. It is then trimmed around the edges, stamped, and formed in a press. The slit is next cut through the solid iridium point by means of a thin copper wheel fed with fine emery, and a saw extends the aperture along the pen itself. The inside edges of the slit are smoothed and polished by the emery-wheel; burnishing, and hammering produce the proper degree of elasticity.

Gold-print'ing. Work printed with gold-size and the letters then covered with gold-leaf, or Dutch-metal.

Gold-rain. (*Pyrotechnics.*) Small cubes ½ inch square, used instead of stars for rockets, etc.

Their composition is niter, 16; sulphur, 10; mealed powder, 4; lamp-black, 3; flowers of zinc, 1; gum arabic, 1; treated in the same manner as for stars.

Gold-shell. Powdered gold or gold-leaf ground up with gum-water and spread on shells. Used by artists.

Gold-size. A size used as a surface on which to apply gold-leaf.

The *oil gold-size* is a mixture of linseed-oil or *fat-oil* and ocher ground by the muller and used in *oil gilding*.

The *gold-size* used in *burnish-gilding* is a peculiar composition, consisting of pipe-clay, red chalk, black-lead, suet, and bullocks' blood, compounded and thinned with a solution of gelatine.

Gold-sol'der. Gold, 12; silver, 2; copper, 4. See SOLDERS, p. 63.

Gold-thread. Otherwise *spun-gold*. A flatted, silver-gilt wire, wrapped or laid on a thread of yellow silk by twisting with a wheel or bobbins.

Gold-tis'sue. Cloth interwoven with gold-thread.

The Persians in the time of Darius were prodigal in vestments of gold embroidery and silk. The nuptial robes of Maria, wife of Honorius, discovered in her coffin in Rome in 1544, on being burned yielded thirty-four pounds of pure gold.

Gold-tool'ing. Ornaments impressed by the hot-tool upon gold-leaf laid on book-covers, causing the metal to adhere. In contradistinction to *blind-tooling*, which is the tool-mark without the leaf. The gold is fixed to the surface of the leather by gold-size, and the surplus is wiped off after the tool has been applied.

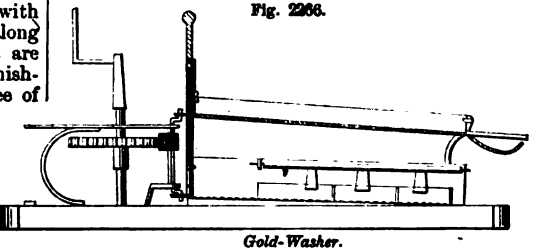
Gold-var'nish. (*Metallurgy.*) A yellow, transparent varnish spread over silver-leaf to give it the appearance of gold. The invention seems to have originated about 1680 with Antonino Cento, an artist of Palermo. It was introdueed into England by Evelyn, 1680. The varnish is made of gum lac digested in spirits of wine.

Gold-wash'ers. Pliny speaks of the method of gathering gold by means of an artificial river and sluices, the water being brought from a distance by canals, and precipitated upon the auriferous earth, which is carried down the trenches, the particles of gold being arrested by the leaves of a prickly shrub planted therein. He says that the water is sometimes brought as much as one hundred miles, the channel being hollowed out of the faces of the precipices and carried by aqueducts across valleys. The prickly plant, the *ulex*, is then dried and burned, and the ashes washed to obtain the gold.

"In the country of the Saones [in the Caucasus] the winter torrents are said to bring down even gold, which the barbarians collect in troughs pierced with holes and lined with sheep fleeces; hence the fable of the "golden fleece" (STRABO). Colchis may be considered the California of old times.

Gold-washers are of various kinds, a number of

Fig. 2266.



Gold-Washer.

which are cited under GOLD-MINING, the machines and devices being also enumerated in the specific index METALLURGY (which see). The pan, the rocking-cradle, the shaking-table (Fig. 2266), the inclined chute, the series of settling-vats, the trough with slats or riffles, the vertically reciprocated sieve, are types of machines which have many varieties and names. The nomenclature of mining is very full, but a large number of its terms are local. In England the miners of Derbyshire and Cornwall have, to some extent, their own sets of terms, and these differ in many respects from those which obtain in the coal regions. See specific list under MINING.

Edrisi, the Arab geographer (about 1150), the friend of Roger II. of Sicily, speaks of the employment of quicksilver in the gold-washings made by the negroes of Sofala as a long-known practice, and the use of this metal in gathering gold has increased with the lapse of time. See AMALGAMATOR.

Gold-wire. Gold-wire, so called, has usually a core of silver, and is made by preparing a round bar of silver, plating it thickly with gold, and then drawing it through a series of holes of gradually decreasing diameter. The gold may be $\frac{1}{100}$ of the thickness of the silver at first and shares all its mutations in the drawing, retaining the same relative

Digitized by Google

thickness. Dr. Wollaston, a man of extraordinary tact in delicate experiments, made the finest wire on record. He bored out a rod of silver, put in it a core of gold-wire, then drew the rod down to wire, dissolved away the silver in nitric acid.

Gold-wire flattened by being passed between highly polished steel rollers forms a ribbon which is twisted around a core of silk to form gold-lace. The compound thread is then twisted or woven into a lace or braid.

Gol'path-en. (*Fabric.*) An Indian striped silk.

Gome; Gorm. Grease for cart-wheels (English).

Gon'do-la. 1. A Venetian pleasure-boat.

"Didst ever see a Gondola? For fear
You should not, I'll describe it you exactly:
'T is a long covered boat that 's common here,
Carved at the prow, built lightly but compactly;
Rowed by two rowers, each called 'Gondolier,'
It glides along the water looking blackly,
Just like a coffin clapt in a canoe,
Where none can make out what you say or do.

'And up and down the long canals they go,
And under the Rialto shoot along,
By night and day, all paces, swift or slow,
And round the theaters, a sable throng,
They wait in their dusk livery of woe, —
But not to them do woful things belong,
For sometimes they contain a deal of fun,
Like mourning coaches when the funeral 's done."

LORD BYRON (*Beppo*).

A gondola of middle size is 30 feet long, 4 feet beam, and is rowed by one man standing at the stern and using one oar. It has a well-furnished cabin amidship, and is painted black. The stem and stern rise in pointed elevations, the former being surmounted by the *ferro*, a bright iron cleaver.

"Two Gundaloes were imported into England by the 'merry monarch' in 1661." — PEPYS'S *Diary*.

2. A flat-bottomed boat (United States).

3. A railroad platform car.

Gong. A Malayan word. A tambourine-shaped resonant bell of the East. A disk of thin bronze with an upturned flange forming a rim. It consists, according to Klaproth, of seventy-eight parts copper, twenty-two parts tin, and is a noisy affair requiring skill in the manufacture, both in the hammering and annealing. The tempering is the inverse of that adopted for iron. The bronze is of such proportions as to be naturally brittle when cast. It is heated to a cherry red and plunged into water, being clamped between iron disks till cool. It will then bear the hammer.

2. A stationary bell whose tongue is moved by a wire or string. Commonly used as an alarm or *call-bell*.

Gon-i-om'eter. An instrument for measuring angles, more particularly those of crystals.

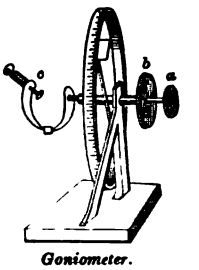
One form of goniometer for measuring the angles of crystals observed through the microscope is attached to the eye-piece, and has a pointer and graduated circle. It was invented by Romá de Lisle, about 1783.

Schmidt's goniometer consists of a positive eye-piece with a single cobweb filament stretched diametrically across it in a circular frame capable of rotation; the edges of the frame are graduated in degrees. By rotation of the frame the filament is placed successively in line with the directions of the two sides of the crystal, and the difference in the degrees is observed.

Wollaston's reflecting goniometer consists of a graduated circle provided with a vernier reading to minutes. The axis of the circle is a hollow tube within which is a smaller axis, each of which has a milled head *a b*, allowing the smaller axis to be turned independently of the circle.

The crystal to be examined is inserted in the holder *c* and fixed by wax, so that its edge may be parallel to the axis of motion; this adjustment is determined by causing a horizontal line seen by reflection from each face of the crystal to coincide with another horizontal line viewed by direct vision. The instrument is then turned until the horizontal object is seen reflected in one of the faces. The smaller axis is then held fast, and the other turned until the index of the vernier is brought to the zero of the graduated limb. The circle with the smaller axis is then turned around till the same object is seen by reflection in the other face of the crystal. The arc passed through by the circle measures the supplement of the angle formed by the two faces of the crystal, and for convenience the supplements are laid down on the circle so that the angle is read directly, avoiding the trouble of calculation.

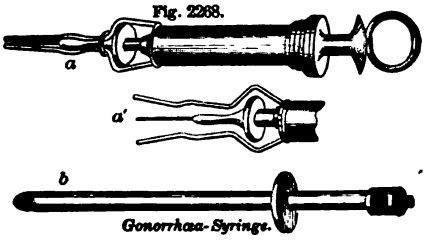
Fig. 2267.



Goniometer.

Gon'or-rhœ'a-syr'inge. (*Surgical.*) An instrument for injecting the urethra. The illustration shows an instrument *a a'* which has a nozzle and three distending fingers. It is introduced in the form shown at *a*, and then distended so as to expand the urethral wall and expose it more fully to the action of the liquid which is ejected at the nozzle. *b* is a form of urethral irrigator having rows of holes throughout a sufficient portion of its length.

Fig. 2268.



Gonorrhœa-Syringe.

Goods-wag'on. The English term for a railway freight-car.

Goose. A tailor's smoothing and pressing iron.

Goose-neck. 1. (*Nautical.*) *a.* An iron fitted at the end of a yard or boom for various purposes.

b. A *davit*.

2. (*Hydraulics.*) A nozzle having a universal-joint connection to the stand-pipe on a fire-engine.

Goose-wing. (*Nautical.*) Another name for studding-sail.

Go-out. (*Hydraulic Engineering.*) A sluice in an embankment for allowing water to escape from tidal lands when the tide is out.

Gore. 1. An angular piece of cloth at the narrowing part of a sail.

2. An angular piece of planking used in fitting the skin of a vessel to the frames.

3. An angular piece inserted into a garment to enlarge or strengthen it. A *gusset*.

Gore-strake. (*Shipbuilding.*) A strake which terminates before reaching the stem or stern-post. Such strakes are at or near the center of the ship to lessen the *spiling* of the plank.

Gorge. 1. (*Fortification.*) A line joining the inner extremities of a work; as, —

Digitized by Google

A line drawn between the rear ends of the faces of a *redan*.

A line across the narrow portion of a *bastion*, from the points of junction of its *flanks* with the *curtains*.

2. (*Masonry.*) A small groove at the under side of a coping, to keep the drip from reaching the wall. A *throat*.

3. (*Nautical.*) The *groove* or *score* of a pulley.

Gorge-hook. Two fish-hooks separated by a piece of lead.

Gor'get. (*Surgical.*) *a.* A lithotomic cutting-instrument.

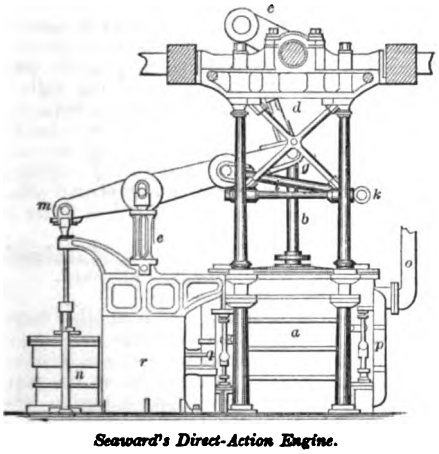
b. A canulated or concave conductor; called also a *blunt gorget*.

Gor'gon-elle'. (*Fabric.*) A Dutch cloth.

Gor'gon Steam-en'gine. A form of direct-action steam-engine, invented by Seaward (Britain), as a means of obviating the use of the beam in *marine-engines*. It is called the "*Gorgon*" engine, from having been first employed in an English government steamer of that name.

a is the steam-cylinder and *b* the piston-rod, which is connected to the crank *c* by the rod *d*. The head of the piston-rod is guided vertically by the parallel motion, as follows: *e* is a rocking standard, carrying at its upper end the fulcrum upon which the beam turns. The beam is jointed at *g* to the cross-head

Fig. 2269.



Seaward's Direct-Action Engine.

of the piston-rod, and also to the radius bar *i*, which turns upon *k* as a center. The outer end *m* of the beam serves to work the air-pump *n*. *o* is the steam-pipe by which steam is conducted to the valve-chamber *p*. *q* is the valve-chamber of the eduction-valve, which is connected to the condenser *r*, the upper portion of which forms the hot-well.

Gos'sa-mer. (*Fabric.*) A very thin gauze.

Gouge. 1. (*Wood-working.*) A chisel with a curved blade adapted to make a rounded groove in cutting or turning wood.

They are known as *flat*, *middle*, and *quick*; their curves being respectively *obtuse*, *medium*, and *acute*.

The gouge existed in early ages in stone, bone, and bronze.

2. (*Bookbinding.*) A finisher's hand-tool for blind-tooling or gilding, having a face which forms a curve.

3. A shaped incising-tool used for cutting out forms or blanks for gloves, envelopes, or other objects cut to a shape from fabric, leather, or paper.

Gouge-bit. A wood-boring tool used in a brace. It has a rounded end, and a groove which contains the chips. See BIT.

Gouge-slip. Oil-stone or hone slip, for sharpening on the concave side of the edge of the gouge.

Gov'ern-or. 1. (*Steam-engine.*) A device which regulates the admission of steam to the engine according to the rate of motion. The intention is to maintain uniform velocity, and any acceleration of speed above a given rate causes a valve to be partially closed, diminishing the area of steam passage; contrariwise in case of flagging in the speed of motion of the engine. The favorite form of governor has a pair of balls suspended from a vertical shaft, so as to swing outward when the shaft is rotated. The greater the speed the greater the centrifugal force, and consequently the farther the balls depart from the axis of rotation; the inclination of the ball arms is made effective in working the valve.

This use of the device of the two suspended revolving balls, whose circle of revolution widens as the speed of the engine increases, is due to James Watt, who adapted it from an ancient device in windmills.

The full-page engraving opposite to page 998 shows fifteen variations in form and structure of the ball-governor, two forms in which a propeller-wheel acts in a liquid, and one form in which the pressure of steam is directly upon the valve.

In *a* the balls receive their rotation from the bevel gearing above, increment of speed causing the balls to fly outward and raise the sliding sleeve on the spindle. To this sleeve is connected the end of a lever arm whose vertical oscillations are communicated to the butterfly or throttle valve, as in Figs. *k* or *l*.

In *b*, the balls receive rotation by the bevel wheels, next below the sliding collar. To the collar is attached a sleeve on which the lower bevel-gears remain at rest as long as the pin on the said sleeve is not in contact with either of the studs projecting from the upper and lower surfaces of the respective bevel-wheels. This is the position shown in the cut, and is that assumed when the engine is running at the required speed. Should the speed be accelerated, the raising of the balls would raise the sleeve and its pin, and thereby rotate the upper bevel-wheel, turning in one direction the miter-wheel with which it engages. If the speed fall below the medium, the pin on the sleeve falls and turns the other bevel-wheel, moving the miter-wheel in the other direction. The horizontal shaft of the miter-wheel operates the throttle valve or gate of the pen-stock.

c acts by substantially the same means through a system of levers upon a belt-shifter. In the medium position the belt runs on a loose pulley; but when the balls rise by acceleration of speed or fall by retardation, the belt is shifted on to the upper or the lower pulley, which pulleys act upon the valve or gate requiring adjustment.

In *d*, instead of the arms being connected with a slide working on a spindle, they cross each other and are elongated upwardly, where they connect with the valve-rod by two short links.

Pickering's governor *e* has balls on springs, the upper ends of which are attached to a collar fixed on the spindle, and the lower end to a collar on the sliding sleeve. The springs bend outward proportionally to the centrifugal force of the balls, and thereby raise the sleeve, acting upon a rod which diminishes the area of induction steam opening. A diminution of speed has the contrary effect.

In *f* the balls ascend the parabolic arms as they fly outward when the motion of the engine is accelerated, and conversely. Anti-friction wheels assist

Digitized by Google

the balls in the ascent. Rods from the axes of the rollers connect to a collar whose motions are communicated to a lever which acts upon the butterfly-valve.

In *g* the upper ends of the ball-arms have cogged sectors which act upon the racks on the axial-rod to depress or raise it.

In *h* the oscillating weighted arm assumes a more horizontal position with increase of speed. Its normal or stationary position is shown in the illustration, its arms being out of poise.

i has balls upon toggle-arms, and resembles figure *e*, in which they are on springs.

In *j* the elbows of the arms are connected by a spring whose midlength is attached to a sleeve which slips on the spindle as the balls rise or fall.

k shows the connection of a governor similar to *a*, with the butterfly-valve of a steam-pipe; and *l* is an illustration of a governor similar to *d*, but driven by a band-wheel below.

Tyson's governor *m m'*, 1861, has its arms suspended from a horizontal axis which rotates with the vertical spindle. He states that his object is to avoid "the friction which resists the free movement of the weighted arms in ordinary governors and attain the desirable sensitiveness." *m* is an elevation, and *m'* a plan view looking upon the balls in motion, showing them swinging tangentially to a circle whose radius is equal to the length of the axis of suspension. When the engine starts, their inertia first comes into play, and increment of speed causes them to rise in the prescribed planes, the balls themselves describing an orbit of increasing radius. It is supposed to be more sensitive than the form in which the balls swing radially outward, but, like them, has the disadvantage of lateral pressure in its bearings, as the balls are compelled to rise in lines which are not the natural result of the forces which actuate them. In Tyson's the line of rise and fall is tangential to a circle of given radius; in the ordinary governor it is directly radial.

In Shive's governor, *n n'*, the balls swing at an angle which is, as seen at *n'*, a compromise between the two last described. The axes of the mandrels on which the ball arms vibrate are tangential to the spindle, at a point distant about the semi-diameter of the ball from the axis of revolution of the vertical spindle. The balls thus swing outwardly and backwardly, so that the inertia as well as centrifugal action of the balls, is brought into play. They are, however, compelled to rise in the prescribed direction, a compromise between the radial and the tangential.

Degener's governor, 1856, was designed to give to the pendulum balls "a motion independent of the motion of the spindle aside from their vibratory motion, by means of the diverging spiral inclines . . . . for the purpose of obtaining a more sensitive action of the pendulums." The collar from which the pendulums are swung is allowed to turn upon the spindle. The spirals are intended to "act under the pendulums and assist in throwing them upward" when the rate is increasing, or downward when the speed is checked. The diverging spiral inclines are of a shape approximating the line of ascent and descent of the ball arms under increment and decrement of speed, and can only permit freedom of motion at one ratio of increase or decrease of speed. Freedom of motion is, however, not intended, but the inclines are intended to compel quick response.

In Knight's governor, Figs. *o*, *o'*, *o''*, *o'''*, the hinging axis of each ball arm has a capacity for adjustment in a plane at right angles to the axis of revolution, so that as the hinging axis permits the vertical motion of the ball, the adjustment in a horizontal plane of the bearing of the said hinging axis shall permit the outward swing of the ball, the two, in fact, forming a universal joint permitting the ball to follow the line of motion due to the speed and the proportions of the parts. In cases where the balls are compelled to rise in a certain plane, they can only do so with perfect freedom when running at one definite speed, and their motion on their hinging axes can never be perfectly free when running above or below the said definite rate; this fact is recognized by the introduction of the usual guides, as at *a b c d k l*, which prescribe the path of motion, and which would be unnecessary were the actions of the balls unconstrained. Any guide or immovable axis which tends to warp the balls from their true line of motion affects the freedom of their movements, entails additional friction, and intercepts or prevents their delicate and instant response to an acceleration or retardation of speed. If, upon an increase of speed, the arms or hinging joints of the balls have a tendency by a lateral strain or pressure to bind or rub, it is manifest that the balls cannot instantly respond, but that a cumulative force and speed will be required to obtain such a response as would more quickly result were the balls perfectly free to respond in their own way; and, in fact, the motion due to the inertia of the balls developed upon an accession of speed and manifested by their tendency to lag behind is much more immediately responsive and active than the tendency to assume a more radial relative position which presently results. In this governor the balls are free to swing in such direction as may be induced by their speed and proportions, ascending or descending under changes of speed in such curves as may result from the combined forces of gravity and centrifugal impulse, under the condition of free pivotal attachment to bearings which are permitted to rotate in a horizontal plane.

Fig. *o* is an elevation of one mode of application of this principle, the balls swinging upward.

o' is a top view of the same.

o'' shows the balls at rest; *o'''* is another form in which a spur or finger from above the hinging joint of the governor arm projects upward, and is jointed to a link pivoted above to a spindle in the plate; the finger and link together form a toggle, which brings the upper plate nearer to the lower one, the two ends of the toggle being hinged in bearings which are capable of horizontal rotation in the respective plates. The downward motion of the balls restores the normal position. The parts may be so arranged as to straighten the toggle by the raising of the ball, if so desired.

Modifications are shown in the patents whereby either the tangential or radial motions of the ball may be utilized, or an effect obtained from the sum of the two motions.

Some other forms than the pendulous ball may be referred to.

p is a governor in which the valve is operated by the direct pressure of steam upon a piston on its stem. The piston operates in a smaller cylinder, taking steam from the main cylinder.

q q' is Huntoon's hydraulic governor, in which a propeller-wheel works in a liquid whose resistance causes the propeller-shaft to rise in a degree proportioned to the rate of speed. The sectoral frame with its draw-pawls has a constant, reciprocating, rotary motion, and when either of the pawls comes in contact with the ratchet, it causes the ratchet-shaft to rotate to actuate the steam-valve. The rocker-frame is actu-

STEAM-ENGINE GOVERNORS.

PLATE XXI.

See page 998.

Digitized by Google

Digitized by Google

ated by the governor, and its cams bring one or other of the pawls in contact with the ratchet, according to the variation of the speed above or below the desired point.

r is a somewhat similar contrivance, in which the longitudinal position of the propeller in the water-cylinder, due to its rate of speed, determines by the connecting rack and segment the position of the valve in the steam-pipe.

Silver's momentum-wheel governor has a heavy revolving wheel, whose momentum acts upon the throttle-valve when any change occurs in the rate of motion of the engine. See also MARINE-GOVERNOR.

The *hydraulic governor* or *cataract* is the invention of Smeaton. A quantity of water is pumped at each stroke, and forced by counter weights through an orifice of a certain size. See CATARACT.

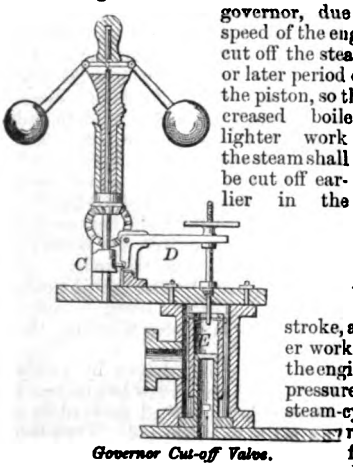
Davis's governor (English) consists of a single hollow ball with a zone round it, having an opening through the bottom to admit of an upright spindle, attached to the ball by a joint in its center. One side of the ball and zone is made much heavier than the other, and consequently, when at rest or moving slowly, it hangs down; but when driven fast, the centrifugal force of the heavy side overcomes its gravity, and the zone assumes a nearly horizontal position. When this is the case, a small link inside the ball, jointed on one side of the axis, lowers the usual brass collar on the spindle, and shuts off part of the steam, till the diminishing speed allows the gravity of the zone to overcome the centrifugal force, and, the link being raised, the throttle-valve is opened under to admit more steam.

In Mosman's chronometric governor, one of two shafts has rotation directly from the engine, its speed being relative to that of the engine. The other shaft has motion from the engine, but its speed is regulated by a pendulum or balance-wheel. A variation in speed causes a longitudinal movement in the shaft which is connected to the governor valve.

2. (*Gas.*) A device which regulates the passage of gas from the holder to the mains, admitting it thereto in quantities determined by the rate at which it is used. The pressure in the mains determines the area of the opening through which the gas enters. See GAS-GOVERNOR.

Gov'ern-or Cut-off. An automatic arrangement in which the acceleration or retardation of the motion of the governor, due to changes of speed of the engine, is made to cut off the steam at an earlier or later period of the stroke of the piston, so that with the increased boiler-pressure or lighter work the steam shall be cut off earlier in the stroke, and when greater work is imposed on the engine or the steam-pressure flags, the steam-cylinder shall receive steam from the boiler during a larger proportion of the stroke of the piston.

Fig. 2270.



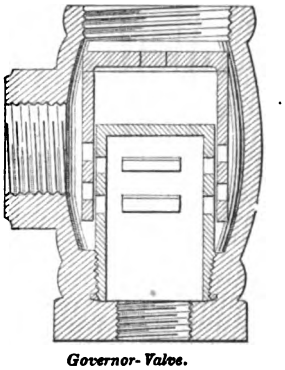
Governor Cut-off Valve.

The combination of the governor with a cut-off valve-gear was first published in the "Repertory of Patent Inventions" for 1826, as the invention of James Whitelaw.

There are many forms of this device, and the applications are made to slide and to puppet valves. In the illustration it is shown as applied to a cylindrical valve. The variable cam *C* on the stem which is raised or depressed by the vertical motions of the governor-balls makes two revolutions to each stroke of the engine. The two distinct fields of the cam have different radii, and act upon the short arm of a bell-crank lever *D* connected at its other end to the stem of a balanced cylinder-valve *E*, which governs the admission of steam to the cylinder.

Gov'ern-or-valve. 1. A valve in a steam-pipe operated by the governor to vary the area of steam, opening according to the rate of moving, and consequently the requirement of the engine; the object being to maintain a uniform rate.

Fig. 2271.

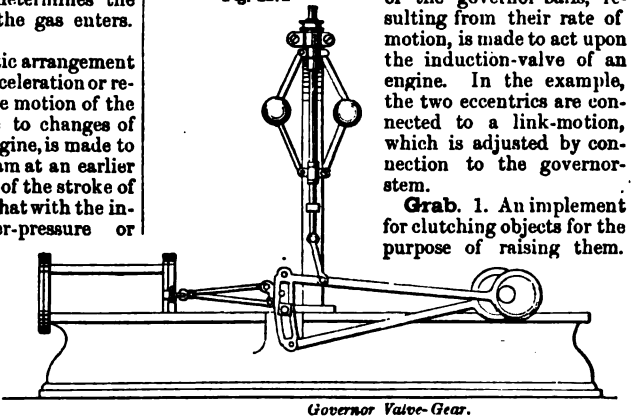


Governor-Valve.

2. A governor cut-off is an induction-valve in a steam-chest, so connected to the governor as to be influenced in its throw by the speed of the latter. When the governor runs at accelerated speed, the period of induction of steam is at the shortest, and the steam is used expansively. When the rate is depressed, the steam induction-port is kept open for a longer time. This variation in the action of the valve is automatic, and derived from the governor. See GOVERNOR.

Gov'ern-or-valve Gear. An arrangement of parts whereby the position of the governor-balls, resulting from their rate of motion, is made to act upon the induction-valve of an engine. In the example, the two eccentrics are connected to a link-motion, which is adjusted by connection to the governor-stem.

Fig. 2272



Governor Valve-Gear.

Grab. 1. An implement for clutching objects for the purpose of raising them. The term is specially applied to devices for withdrawing pipes, drills, reamers, etc., from artesian, oil, and other wells which are drilled, bored, or driven.

Two forms are shown: one has a pair of serrated jaws, which embrace the pipe or rod and bite upon it when the grab is lifted.

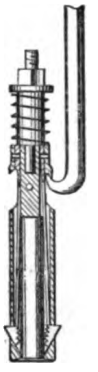
In the other form, the serrated jaws of the hollow cylinder are driven down upon the tool to be extracted, and by their inclined rear faces and locking

Digitized by Google

collar grasp the same when the grab is lifted. To detach the grab, the collar is lifted by the hook.

Fig. 2273.

Fig. 2274.



Grabs.

2. A large East Indian coaster, two masted, with a prow stern, and of from 150 to 300 tons' burden.

Grade. The inclination from the horizontal of a portion of a road or railroad. It is expressed in degrees, in feet per mile, or as a foot in such a distance; as, —

A grade of 3°.

A grade of 35 feet per mile.

A grade of 1 foot in 240. See INCLINED PLANE.

Gra'di-ent. (*Civil Engineering.*) The inclination of a slope.

Gra'di-ent-post. 1. (*Railroad Engineering.*) One placed by the side of the track, at a change of grade, carrying a board slanted to the slope and indicating in figures the grade in feet per 100, or otherwise.

2. A stake set in the ground and marked to indicate the proper hight of an embankment or of road metal at that point.

Gra-dine'. A toothed chisel used by sculptors. See MARTELINE.

Grad'ing-in'stru-ment. A level with an alidade, a transit or other sighting instrument, by which the angle of inclination of a slope may be measured, or a row of stakes driven to mark a given gradient.

Grad'ing-plow. One used for breaking up soil or plowing down banks, in order to fit the earth for being scooped up by the earth-scraper, and thereby deported.

Grad'ing-scrap'er. A large two-handled shovel drawn by a pair of horses and used as an earth-scoop for raising and removing loosened earth. It is used in road-making, scooping out beds of canals in certain situations, and otherwhere when the soil is suitable and the distance where it is to be deposited is not too great. See EARTH-SCRAPER.

Grad'u-at-ing-in'stru-ment. The work of graduating or dividing instruments of precision, though now very generally performed automatically, was formerly effected entirely by hand, by stepping off the successive divisions of the scale or circle, or by successive bisections of a line or chord. This latter naturally suggests itself with regard to a line, but with a circular arc the case is different; there, if it is desired, as is universally the case, to preserve the division into degrees, after the radius has been applied six times to the circumference, giving arcs of 60°, the farther subdivision requires trisections and even divisions into fifths, operations which are very difficult to perform in practice without the aid of very accurately constructed mechanism.

Roemer, in constructing a circle, decided rather to rely on stepping-off arcs of about 10, and applying a subsequent correction for any discrepancy which should exist between the number actually laid down and that which should be contained in a quadrant of the circle. Dr. Hooke proposed the employment of an endless screw for dividing the edge of his quadrant, and this was actually used by Tompion in graduating Flamsteed's sector, probably under the supervision of Hooke.

Graham, who attained great reputation as an instrument-maker as well as clock-maker, adopted the principle of continuous bisections by means of a beam-compass. In the instruments constructed by him for Halley and Bradley, the arc of 60° was divided into 64 parts, making 96° instead of 90° to the quadrant. It was deemed preferable to make the proportionate correction on each angle, rather than to trust to the uncertainty of a division to thirds or fifths.

Bird, 1750, subsequently improved the system by constructing scales of equal parts, enabling him to preserve the division of 90° by successive bisections. His manual skill and care procured him merited reputation as a maker of accurate instruments.

Ramsden followed with his dividing-engine, 1766, the general principles of which, variously modified and improved by Troughton and others, are still employed in the construction of like instruments.

In this, a horizontal wheel, turning on a vertical axis, has a toothed edge, which is advanced a certain amount, say 10′ of arc by each revolution of an endless screw with which it gears. The screw is turned by a treadle, the connecting mechanism being such that it may be adjusted to turn a whole revolution or any desired part of a revolution by a movement of the treadle.

For this invention he received a reward of £600 from the British government, on condition of executing the divisions on the instruments of other makers at a fixed price for each instrument. An instrument of this kind, by Troughton & Sims, is in the Coast Survey Building, Capitol Hill, Washington.

Hindley, 1740, had invented a dividing-engine, upon which this of Troughton is said to have been based. It also served for cutting the teeth for clock-wheels. See also DIVIDING-ENGINE.

In addition to original graduation by the beam compass and engine, the dividing of a scale or a circle is performed (and this is the most common practice with regard to ordinary instruments) by means of a *dividing-plate*, which is itself originally graduated with great care. This consists of a circle carrying a pivoted straight-edge, and is fixed to and concentric with the circle to be divided. The straight-edge is moved, step by step, a distance, 10′ or 15′, indicated on the dividing-plate, and at each move a clean straight cut is made in the limb of the instrument being graduated. The knife has one flat side and somewhat resembles a graver, but is drawn toward instead of being pushed from the artist. At each degree the marks made are longer, their length, and that of the smaller divisions, being bounded by concentric circles previously described on the limb.

Froment invented a machine, driven by rotary electro-magnets, in which the object to be graduated was slowly and intermittingly pushed forward by a screw, while a fine steel or diamond point was automatically caused to make a cut at each cessation of the feeding motion. He thus succeeded in crowding 25,000 lines, with distinct and equal intervals between them, within the space of an inch. Nobert

Digitized by Google

succeeded in ruling more than eight times as fine. See NOBERT'S TEST-PLATES.

Whitworth has graduated micrometers by which the almost inappreciable quantity of one millionth of an inch can be measured. See DIVIDING-ENGINE; MEASURING-MACHINE.

Grad'u-a'ted-bot'tle. One having horizontal marks blown, pressed, or cut on its side to indicate quantity of contents at given levels. Sometimes the stopper is hollow, forms a cup, and has graduations for doses of certain amounts.

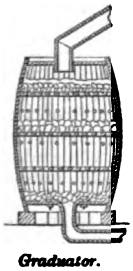
Grad'u-a'ted-cup. A medicine-cup, on whose sides are marks to indicate quantities at given levels. If of glass, they are usually impressed in the mold; if of porcelain, they are painted on the ware before burning.

Grad'u-a'ted-glass. A tube with a foot, and with horizontal marks at varying hights to indicate quantity of contents. A *measuring-glass.*

Grad'u-a'tor. An apparatus in which a solution is allowed to trickle over a large extent of surface, during which it is exposed to a current of air.

This is adopted in the salt-works of Montiers, in the Tarantaise, Switzerland, where brine having 1.83 per cent of saline matter is condensed to such a degree of saturation as to be profitably evaporated by boiling. It is trickled over fagots of thorns placed in frames, and acquires a density of 22 per cent.

Fig. 2275.



Graduator.

Another plan is to let it trickle over suspended ropes upon which it crystallizes and is broken off. The ropes last twenty-five years; the fagots, seven years.

Vinegar is manufactured by exposing a large surface to oxidation in a similar manner, the cider or alcoholic solution being suffered to trickle through a vat filled with beech shavings, through which a current of air is simultaneously passed.

Wort is cooled by trickling it over pipes through which a stream of cold water is continuously passed. (See BEER-COOLER.) In De Grand's condenser the saccharine juice is passed over a succession of steam-heated pipes, in order to condense it before reaching the vacuum-pan. See CONDENSER.

Graft'ing. 1. (*Carpentry.*) A scarfing or endwise attachment of one timber to another, as in attaching an extra length or false pile to one already driven.

2. (*Nautical.*) The tapering of the end of a rope; usually covered by weaving yarns around it.

3. (*Husbandry.*) The placing of a scion of a particular variety of tree or shrub in a stock of its own or a closely allied species.

4. (*Surgical.*) The transplanting of a portion of skin to a denuded surface.

Graft'ing-chis'el. (*Husbandry.*) One for splitting a stock for the insertion of a scion.

Graft'ing-knife. A knife having a blade for splitting a limb and a wedge for opening the cleft for the insertion of the scion.

Fig. 2276.

Grafting-Knife.

It is used in connection with a mallet.

Graft'ing-saw. A tenon-saw for cutting off stocks for grafting. A *pruning-saw.*

Graft'ing-tool. A very strong spade; much curved, used in digging canals.

Graft'ing-wax. Rosin, 6; beeswax, 1; tallow, 1; melted together, to be used warm when grafting indoors. Rosin, 4 or 5; beeswax, 1½ to 2; linseed-oil, 1 to 1½, for outdoor work the proportions varying with the season and temperature. French recipe: Black pitch, 28; Burgundy pitch, 28; beeswax, 16; grease, 14; yellow ocher, 14.

Melt 4 parts beeswax; 1 part Canada balsam (balsam of fir); pour while hot on thin paper, so as to cut in strips for convenient use; a little vermilion added keeps insects from the scion.

Another grafting composition used by nurserymen is clay tempered with water, to which a little linseed-oil is sometimes added.

Graille. A *single-cut* file, or *float*, having one curved face and a straight one, used by comb-makers. See COMB.

Grain. 1. (*Weight.*) The unit of weight in the English system. 7,000 grains make one pound avoirdupois, and 5,760 grains one pound troy, or apothecary's weight. See POUND; UNIT.

2. (*Painting.*) A style of painting in imitation of the natural *grain* of wood.

3. The *hair* side of skin; in contradistinction to the *flesh* side.

4. (*Dyeing.*) Formerly, a red dye prepared from the *coccus* insect, or *kermes.* Now applied to a firm dye as one applied thoroughly; in the *wool*, not in the *web.*

5. The direction of the fibers in wood, etc., and of the strata or cleavage in stone, slate, etc.

Grain-bin. A box or a compartment in a granary or elevator in which grain is stored. In the large buildings for trans-shipping and storing grain, and known as *elevators*, the apartment at the top of the building into which the grain-cups discharge has distributing-pipes to the various bins, and these have funnel-shaped bottoms and valves for discharging their contents. See ELEVATOR.

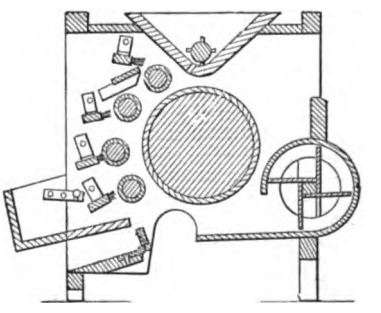
Grain-bind'er. An attachment to a harvester for binding a gavel into a sheaf. See REAPER.

Grain-bruis'er. The grain-bruiser is for mashing grain for feed, to render it more digestible. It does not amount to grinding, but crushes the kernel, corn, or oats, and puts it in a better condition for feed, for obvious reasons which need not be explained here. It is a very common practice in England, and will be here when economy is much studied. A *bruising-mill.* See GRINDING-MILL.

The machine has two iron rollers of differing diameters, which are turned by connecting cog-wheels of the same size, so that a rubbing is added to the crushing action. A fluted roller below the hopper receives the grain from the hopper and feeds it to the rolls. See OIL-CAKE BREAKER.

Grain-clean'er. 1. A machine in which wheat, oats, rye, and barley are separated from their chaff,

Fig. 2277.



Grain-Cleaner

Digitized by Google

dust, and pieces of straw, — the result of the thrashing operation. A FANNING-MILL; a WINNOWING-MACHINE (which see).

2. The shoe or cleaning portion of a thrashing-machine which acts after the thrasher and the straw-carrier. See THRASHING-MACHINE; SEPARATOR.

3. A machine in which grain is rid of cockle, garlic, etc., which are so nearly the size and weight of the grain that the size of mesh and strength of blast of the fanning-mill are ineffective. Fig. 2277 shows one form, in which the cylinder has a hard periphery which is held in contact with the smaller rollers by springs; the latter have soft surfaces, which catch the cockle, garlic, etc., and carry it away to be removed by brushes and separately discharged, while the dust is blown away by a fan.

4. A machine in which grain is rubbed, brushed, and blown to remove smut and dust. See SMUT-MACHINE.

Grain-con-vey'or. A series of cups on an endless band, an archimedean screw, or a blast of air to carry grain in a conductor from one place to another, in a *thrasher*, *grain-cleaner*, *smut-mill*, *mill*, *warehouse*, or *elevator*.

Grain-cra'dle. A light, four-fingered frame attached to the snath of a grain-scythe so as to catch the cut grain and allow it to be laid evenly in a swath.

Our four-fingered grain-cradle, whose post is braced by rods, and whose swath has a single nib for the right hand, seems to have originated in France; Loudon (1844) speaks of it as an ordinary tool in Normandy.

Grain-damp'er. A device for applying steam to grain to scald the bran and facilitate the process of decortication. A jet of steam entering a tube where the grain descends a series of inclines is a usual method.

Grain-drill. A *grain-drill* may sow one or more rows of seed, but a *drilling-machine*, by common consent apparently, is adapted for "sowing seed in equidistant rows, on a flat surface; on the top of a narrow ridge; in the interval between two ridges; or in the bottom of a common furrow. Small grain, when drilled, is usually sown in the first of these ways, turnips in the second, and peas and beans in the third and fourth." — LOUDON.

The first notice we find of a grain-drill is in that repository of the wonderful, — China. The Chinese machine is a wheelbarrow with a hopper for the seed, and three spouts, twenty-eight inches long, by which the grain reaches the ground; it thus drills three rows at once.

It appears from a communication to the British Board of Agriculture, that a rude sort of grain-drill has been in use in India from time immemorial. It is a drilling hopper attached to a plow so as to deposit the seed in the furrow.

The first notice of a European grain-drill is one invented by a German, and presented to the court of Spain in 1647. The same drill attracted the attention of the Earl of Sandwich, who sent one to England. Evelyn, who died in 1706, speaks of it as a machine of great merit, and the invention of a Spaniard, Don Joseph de Lescatello. Worlidge, in his "Husbandry," published 1669, also recommends it. It was fastened to the tail of a plow, and dropped the seed in the furrow.

It was regarded as a curiosity merely, until a man appeared who was able to appreciate it.

The system of drill husbandry of Britain is the invention of Jethro Tull, a farmer of Berkshire, England, who was an original thinker and innovator. He introduced his system in 1701, and published his "Horse-hoeing Husbandry" in 1731. His special object in drilling was to put the plants in rows, which would allow them to be hoed by machinery. He brought brains and money to the scheme, and impoverished himself, being rather too far ahead of his time. As Loudon observes, he "had very few followers in England for more than thirty years." He died soon after the publication of his book, and his son died in a debtors' prison, when such things were. Not so very long ago.

Jethro Tull's first invention was a kind of plow, with drill attached, for sowing wheat and turnips in three rows at a time; it consisted of two seed-boxes with a colter attached to each, and following each other; behind them followed a harrow to cover in the seed. His object in having two separate deposits of seed, and at different depths, was that they might not sprout at the same time, and so perhaps escape the ravages of the fly; he also invented a turnip-drill.

About 1790, Baldwin and Wells of Norfolk, England, contrived several ingenious improvements to the machine, the first of which was in making a sliding axletree, by which the carriage-wheel could be extended when necessary to the width of the stitches (lands), and so enable another box with cups and more colters to be used. A drill containing fourteen colters could be thus enlarged to contain eighteen, or even twenty.

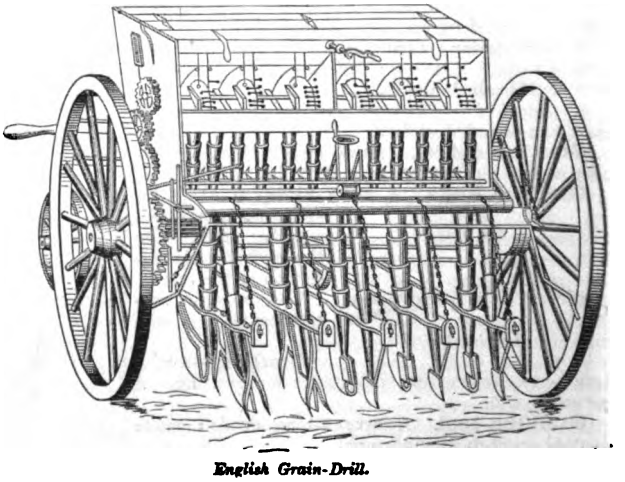
They also constructed self-regulating levers, to which the colters were attached; by hanging each colter on a separate lever, each lever swinging by an ordinary hinge-joint, and having a movable weight at the outer end to press the colter into the soil to the required depth.

After Tull, the machine was much improved by James Cooke, a clergyman, of Lancashire, England; his improvements have been adopted in almost all of the subsequent machines used in English husbandry.

Mr. Ransome states: —

"The seed-box is of a peculiar shape, the hinder part extending lower than the forepart. It is di-

Fig. 2278.

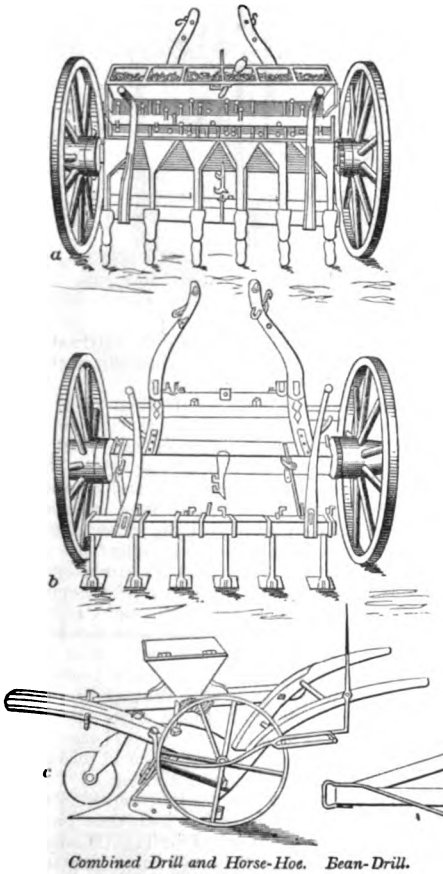


English Grain-Drill.

Digitized by Google

vided by partitions, and supported by adjustable bearings so as to preserve a regular delivery of the seed, while the machine is passing over uneven ground. The feeding cylinder is made to revolve by a toothed wheel, which is fixed on each end of the main axle, and gears with other toothed wheels on each end of the cylinder; the surface of the cylinder is furnished with a series of cups, which revolve with it, and are of various sizes, according to the different seeds intended to be sown. These deposit the seed regularly in funnels, the lower ends of which lead immediately behind the colters,

Fig. 2279.



Combined Drill and Horse-Hoe. Bean-Drill.

which are connected by a beam so as to be kept in an even line, and are capable of being held out of working, when desired, by a hook and link in the center. The seed, as it is deposited, is covered in by a harrow fixed on behind. The carriage wheels are larger than usual, by which means the machine is more easily drawn over uneven ground, and the labor of working is reduced."

Garrett's grain-drill (English) is adapted for performing all the various operations of seeding and manuring the land. All kinds of grain and seeds may be deposited at any required distances apart, and at any depth, either with or without compost or artificial manures.

They are constructed of various widths, and made to deposit the seed in rows from six to fifteen in number, and to suit all descriptions of land, whether ploughed flat or in ridges. The corn and manure are sometimes sown through the same delivery-tubes, but it is better when double tubes and colters are adopted, as the seed is then buried two or three inches deeper than the manure (as before described), and a portion of mold placed between the two. The boxes are suspended on a center in the middle of the machine, and may be elevated or depressed, at either end, by means of a lever, so as to keep them at all times in a horizontal position, and to insure a regular delivery of both on hilly as well as on flat lands. This arrangement admits of the barrels, which deliver the manure and seeds, being driven by gear at the ends of the boxes in the usual way, thus avoiding all unnecessary complication.

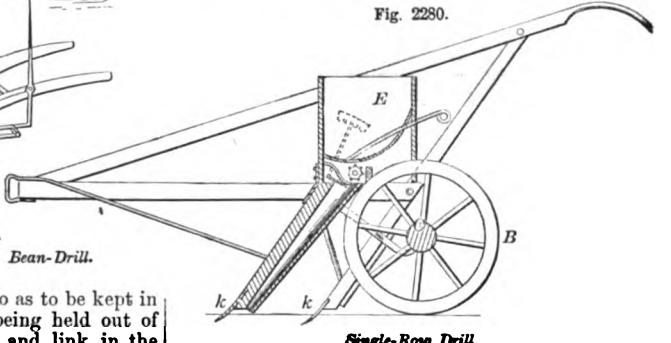
Hornsby, of England, was the first to apply india-rubber tubes as grain-spouts in place of the cumbersome tin cups.

Cooke's drill and horse-hoe *a b* (English) is a convertible machine, the seed-hoppers, shares, and grain-conductors being attached when required. When the crop is to be tended, any kind of share or colter is substituted for the seeding apparatus, as, for instance, the hoes of the illustration. These are attached to the beam previously occupied by the furrow-openers, and may be made to follow with exactness the intervals between the rows of growing plants. The beam is attached by a parallel arrangement to the carriage, and has a pair of handles by which it is swerved laterally to maintain the straight line if the horse deviate. The beam may be raised, and hooked up so as to keep the shares out of the ground during transportation or in turning.

The English bean-drill *c* draws a furrow in the prepared soil and sows a row at the same time. The wheel regulates the depth of the furrow, and a lever throws the drill out of gear when turning at the end of the land.

Fig. 2280 is a form of hand-drill, mounted upon a stock resembling a single-shovel plow, and resting upon a wheel; forward is the hollow tube shod with a share *k*, and leading the grain from the box *E*. A

Fig. 2280.



Single-Row Drill.

share *k*, following, turns a furrow upon the sown grain, and the wheel *B*, following, compacts the soil upon the seed.

Fig. 2281 is a vertical transverse section of the usual American grain-drill, which is drawn by a pair of horses, and has a gang of shares in one or two banks; some varieties of this drill have a capacity for changing to a single or double bank drill.

In the example, the feed-wheel at the bottom of the grain-box *E* is driven by gearing from the ground-wheel *C*, and discharges into india-rubber spouts which lead the seed into and through the hollow share *H*.

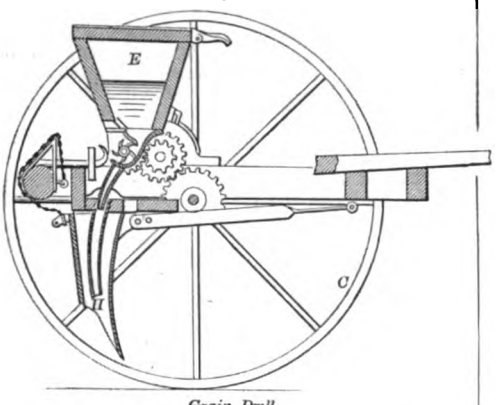
Fig. 2281.



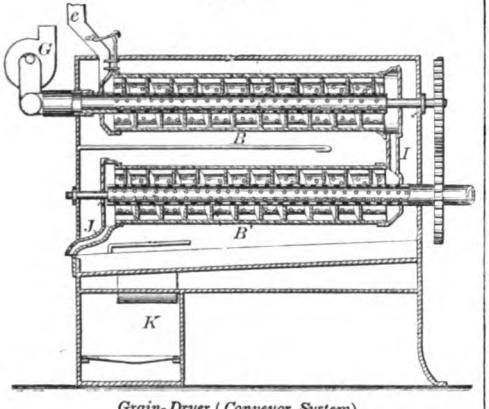
Grain-Drill.

Grain-dry'er. An apparatus or machine in which damp grain is dried, or grain in ordinary condition is kiln-dried to fit it for ocean shipment.

There are many forms of the device, which generally agree in that they afford means for exposing a shower of grain to a current of highly dried and heated air. The following kinds may be cited, and it must be understood that there are many varieties and modifications of each.

1. The *conveyor* system, in which the grain from spout *e* passes consecutively through the cylinders *B B'*, in each of which is a rotating screw conveyor driven by cog-wheels and having for axes hollow

Fig. 2282.



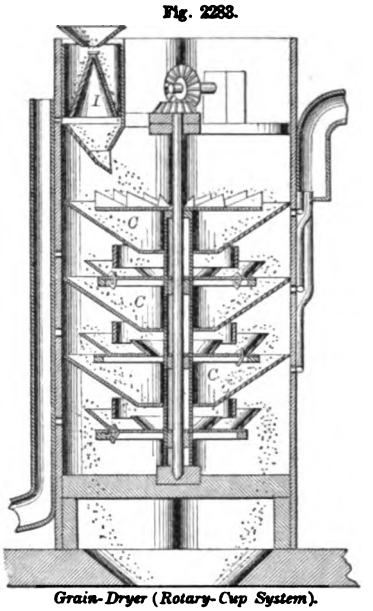
Grain-Dryer (Conveyor System).

perforated tubes, through which the damp air passes from the grain, being drawn by the exhaust fan *G*. The cylinders connect by the spout *I*, and the lower one discharges by the spout *J*. The heated air from furnace *K* rises into the chamber above and surrounds the cylinders.

2. The *revolving-cup* system. In the example the grain enters upon a heated cone *I*, and thence passes to a revolving flanged disk which distributes it to be again collected by the hopper *C*, fed to another disk, and so on down through, in descending series, to the discharge-spout. A current of heated air ascends through the chamber and envelops the grain at all times.

3. The *zigzag-incline* system, shown at *A* (Fig. 2284). The grain descends from a hopper and is

Fig. 2283.



Grain-Dryer (Rotary-Cup System).

shifted over from side to side by the alternate inclines, which are perforated plates in a flue occupied by an upward current of heated air.

4. The *annular drum system B* (Fig. 2284) consists of a vertical double cylindrical chamber with conical ends. The space between the inner and outer casing is the one traversed by the grain, which enters at the apex of the upper cone and departs at the apex of the lower one. The inner and outer casings are all perforated with holes, about 2,300 to the square foot, and the punching being from without, inward, the slight roughness has a tendency to turn the grain which rubs against the protuberances, giving a sort of stirring action to the grain, and aiding the exposure of its whole surface to the stream of heated air. The heat is generated by a stove in the interior of the chamber, and the heated air passes through both casings and through the body of grain contained between them. The apparatus stands upon legs so as to elevate the discharge opening that the falling grain may be received into sacks or grain-barrows for shipping or binning.

A damper or valve at the discharge opening regulates the area of the exit orifice, and thus governs the speed of the passage, determining thereby the time which the grain shall occupy in its transit, according to its condition and the necessities of the case.

5. The *spiral-flue* system *C*, which consists of a long spiral tube traversed by a flue from a stove. The sides of the tube are full of fine perforations, and the draft is upward between the two surfaces and outward through the perforations, carrying the moisture from the grain, which descends in a shower between the flue-pipe and the perforated casing.

6. The *traveling-belt* system *D* consists of a furnace air-box and traveling-belt which receives its grain from a hopper. Grain from hopper *a* falls on to belt *b*, which travels over the grated top of the box *c*, which is heated by air from fan *d* and tubes *e* which form the box and basket grate of the furnace. After passing the length of the box the grain is caught between the belts *b* and *f* and returned to the hopper for a repetition of the operation, or as it descends is intercepted by a spout.

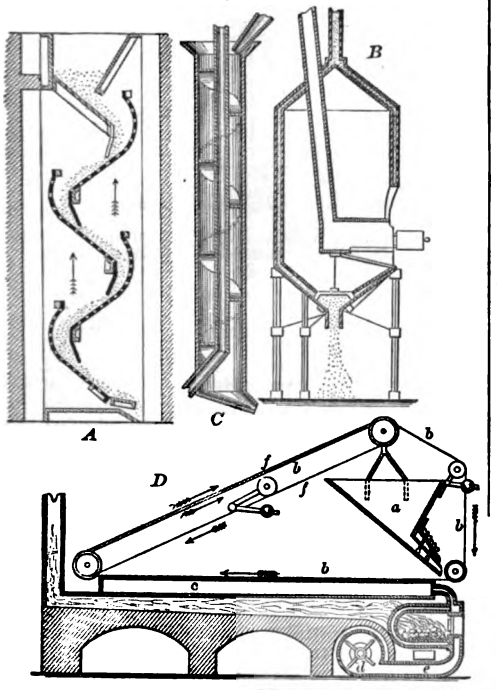
Digitized by Google

7. The *rotary-drum* system, in which an inclined cylinder of wire contains the grain which tumbles over and over, and eventually is discharged at the lower end of the cylinder, which rotates in a chamber heated by a furnace.

8. The *floor-and-scraper* system, in which grain passes from floor to floor, scrapers distributing and discharging it on and from the respective floors in the series.

E F (Fig. 2284) show two forms of this. In *E* the upright cylindrical chamber has a series of cir-

Fig. 2284.



Grain-Dryers.

cular perforated floors, with alternate central and marginal discharge apertures. Rotary conveyors, alternately centrifugal and centripetal, convey to the apertures the grain which falls from floor to floor.

In the other example *F* the grain is moved alternately to the right and left, over finely perforated plates, by the slats or endless chains which pass over the plates. Hot air from a blast or other means passes upward through the plates and grain. The grain drops from the end of each plate to the one immediately beneath.

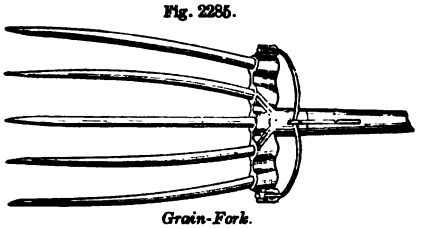
Grain'er. 1. The brush used in *graining* or imitating woods.

2. An infusion of pigeon's dung for giving flexibility to skins in the process of tanning. Also called *bate.*

3. A knife used by tanners.

Grain-fork. A light fork with long and curved tines, used for pitching gavels of cut grain on to a

Fig. 2285.



Grain-Fork.

wagon when the straw is too short for convenient binding. A *barley*-fork.

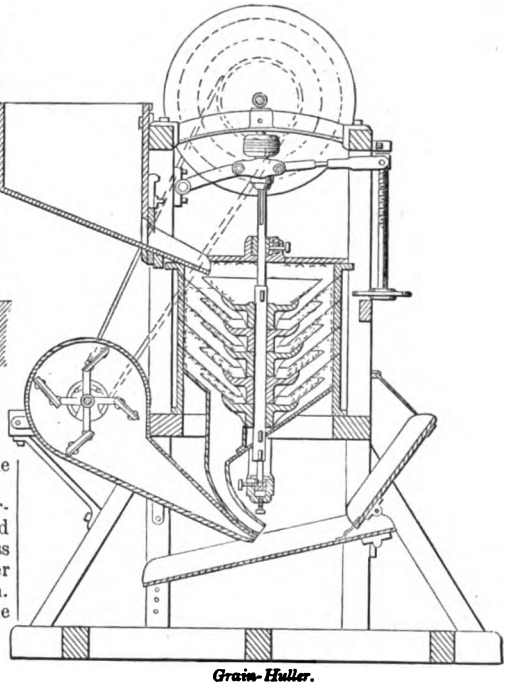
Grain-gage. A device for weighing grain. It has a measure of given capacity, and a scale beam which is graduated to give the weight in pounds and fractions of a measured bushel.

Grain-har'vest-er. A machine for cutting standing grain. There are many varieties, and the idea is as old as the time of Pliny, A. D. 79. In his time the plains of Gaul were reaped by a machine driven by one ox harnessed between shafts. The head of the grain was cut from the straw and fell into a large box which formed a part of the machine. See REAPER; CLOVER-SEED HARVESTER.

Grain-hull'er. A machine for taking the cortex or skin from grain, making hulled wheat, pearl barley, hominy, as the case may be. Known also as a *decorticator, debranning-machine, hominy-machine,* etc.

Wheat is slightly scalded with steam and then fed

Fig. 2286.



Grain-Huller.

Digitized by Google

between roughened surfaces in motion, or it is rubbed between stones or disks which are set at such a distance apart as not to grind it. In the example, inclined serrated plates are attached to the case of the machine and intervene between similar plates attached to the vertical revolving shaft. The grain is alternately ejected from the latter and returned by the former, and is thus subjected to the succession of rasping devices, and is eventually discharged at the bottom of the case and cleaned by a blast of air. See COTTON-SEED HULLER; HOMINY-MILL, etc.

Grain'ing. 1. (*Leather Manufacture.*) *a.* The process of rubbing leather with a board to *raise* the *grain.* The leather having been shaved to a thickness at the beam, and daubed, is hung up to dry, and is then folded, grain side in, and rubbed on the flesh side with a *pommel* or *crippler* to give the leather a granular appearance and render it supple. See CRIPPLER.

The hide is then extended and rubbed on the grain side. This is termed *bruising.*

b. A process for giving markings to a surface of leather to imitate the wrinkled appearance of morocco, hog-skin, and some other leathers.

2. (*Painting.*) The imitation of the natural grain of wood by means of tools. Combs, brushes, and the corner of a folded rag, are used in making the various patterns.

3. (*Lithography.*) A mode of giving a certain texture to the face of a stone. One stone is laid upon another with a quantity of sifted sand of a given fineness, and, by a peculiar oscillation and gradual progression, the surface is cut into a set of fine prominences more or less deep and distant, according to the character of the work to be placed upon the stone.

Grain'ing-board. (*Leather Manufacture.*) *a.* A board on which leather is spread while being grained by the *crippler.*

b. A board with a surface impressed or engraved with a pattern, in imitation of the natural grain of some kind of leather, and used to confer the same appearance upon other leather by pressure.

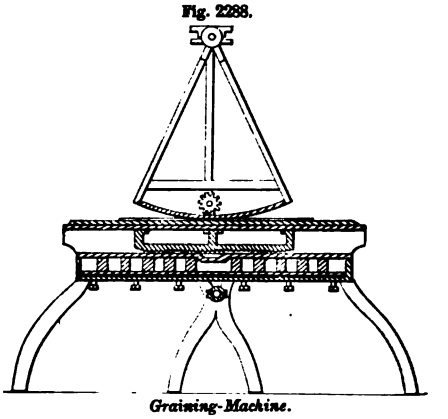
Grain'ing-ma-chine. 1. A roller with a pattern surface representing the grain of wood, and used to transfer the pattern in paint to wood. In the example (Fig. 2287), the roller is an elastic air-bag, which receives its paint from an endless graining-belt.

In the graining-machine for buckets the pail is placed on a block rotated by a winch, and the pattern roller is brought alternately in contact with the pail and inking-roller by the action of a treadle and weighted cord. The surface of the pattern roller is made in removable segments, so that the pattern may be varied in imitation of staves of different woods.

2. (*Leather Manufacture.*) A machine having rollers with raised, parallel, straight, or diagonal threads, which indent the goat or sheep skins and confer the wrinkled appearance to morocco leather.

In the example, the horizontal table vibrates beneath the swinging sector, whose surface has the grained pattern which is to be impressed upon the leather which is between the sector and the table. The graining is sometimes given by hand, by boards or rollers pressed upon the grain side of the leather.

Fig. 2288.



Graining-Machine.

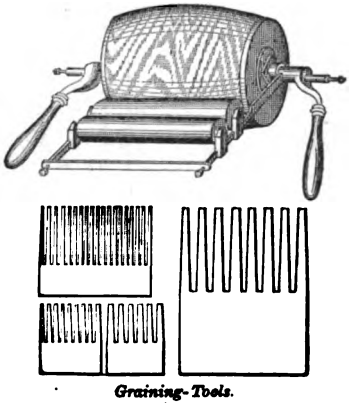
Grain'ing-tool. Hand-tools resembling combs (Fig. 2287), for imitating in painting the lines which represent the growths of timber. A light-colored coat of paint is allowed to dry and a darker coat laid over it. While this is yet damp, it is marked by the graining-tool, which removes some of the darker paint and leaves white stripes behind it. The graining-tools are of steel, horn, wood, or leather, are of different grades of fineness, and have varying numbers of teeth.

Grain-leath'er. 1. Dressed horse-hides.

2. Goat, seal, and other skins blacked on the *grain* side for women's shoes, etc.

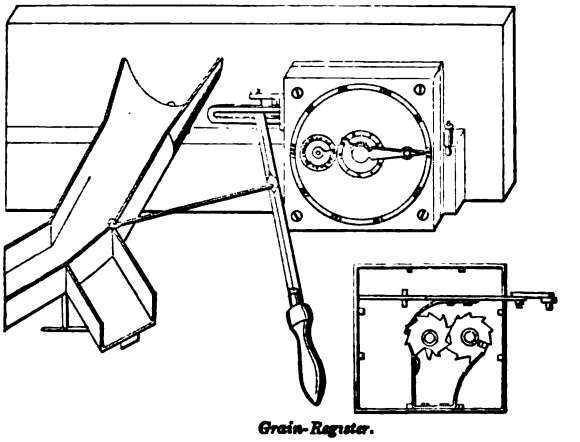
Grain-me'ter. A means for measuring grain,

Fig. 2287.



Graining-Tools.

Fig. 2289.

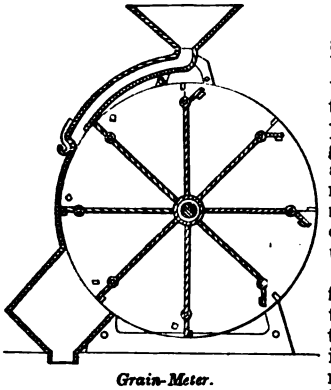


Grain-Register.

Digitized by Google

sometimes by bulk, but more usually in the great grain markets of the United States by weight, as the bushel of grain of a given grade of quality has a legal weight. In the example, a measure is placed under each branch of the chute, and as the gate is moved to direct the grain into either branch the act is denoted by the register, which simply keeps count of the number of motions of the handle. This may be used on thrashing-machines and in filling measures from granaries, but is not so well adapted for the larger needs of the warehouse and elevator. (See ELEVATOR.) In these, a hopper is poised at the end of a graduated beam, weighted for a given number of bushels, say fifty. As the beam rises, the valve at the bottom of the hopper is pulled, the grain discharged, and the process repeated. Automatic registering devices may be used.

Fig. 2290.

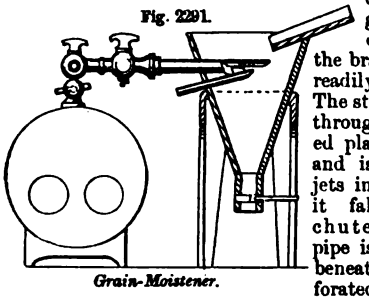


Grain-Meter.

In another form (Fig. 2290) the space between the disks is partitioned by radial divisions into receptacles for grain as it falls from the hopper; the spaces are successively presented for filling and discharging by the revolution of the shaft. The rotations of the wheel are registered by a system of wheels, like the gas-meter.

Grain-moist'en-er. A device for damping the cuticle of grain, in order to enable the bran to be more readily removed. The steam is forced through a perforated plate or shield, and is thrown in jets into wheat as it falls from a chute. A drip-pipe is placed just beneath the perforated shield and carries off the condensed steam.

Fig. 2291.



Grain-Moistener.

Grain-rake. 1. A rake used in raking grain in the swath into gavels for binding.

2. A rake used by one who rides on the reaper in raking gavels from the platform of the machine.

Grains. 1. A residuum of fiber and insoluble matters after infusion or decoction; as the *grains* of malt after the wort is decanted.

2. A harpoon with several barbs. A five-pronged fish-spear.

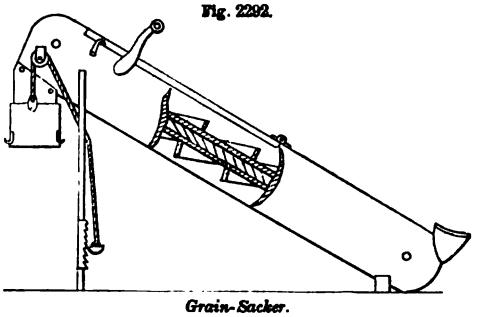
3. Prongs, as of a fish-spear or fork.

4. A *baling* solution of birds' dung, used in destroying the effect of lime, and in improving the flexibility of leather.

5. Pieces of sheet-metal, cast-iron, or tinned iron inserted into a mold for the purpose of supporting an accessory portion, such as a *core*, in position.

Grain-sack'er. A device for sacking grain. In the example, the grain is raised by an endless apron and buckets, and is discharged through an adjustable tube, to which bag hooks are attached. See BAG-HOLDER.

Fig. 2292.

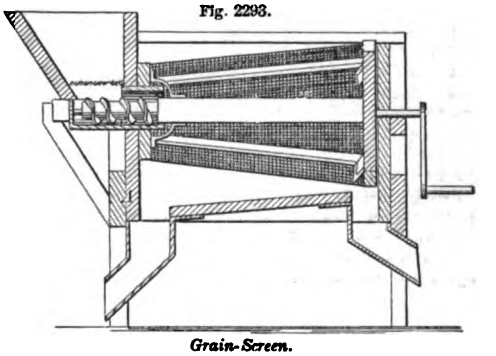


Grain-Sacker.

Grain-scour'er. A machine for cleaning grain. A *smut*-mill. A machine in which grain is rubbed and chafed, and eventually sorted into qualities by gravity and blast.

Grain-screen. A shaking sieve, or a rotating cylindrical reel of wire-cloth in which grain is sorted by quality, according to its ability to pass through the meshes of the sieve. The grain-screen is a part of every fanning-mill: it is also used in the *separator*, which is a thrasher and cleaner. It is also used as a means of cleaning grain from cockle, cheat, grass-seeds, and dust; especially wheat for seed.

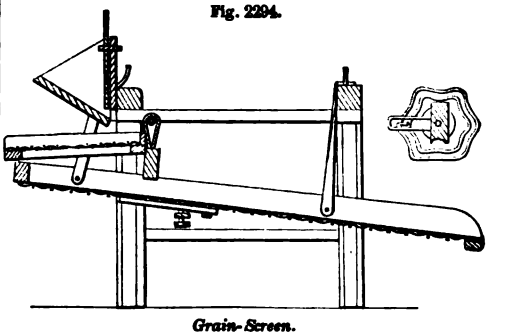
Fig. 2293.



Grain-Screen.

Fig. 2294 shows a reciprocating form of the device; the riddle and screen are suspended upon adjustable straps and have a very rapid motion communicated by means of a cam-wheel and lever. The riddle is agitated in the opposite direction to the screen.

Fig. 2294.



Grain-Screen.

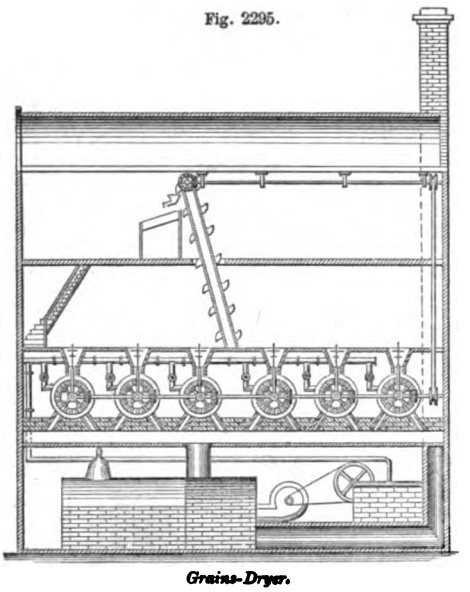
Grains-dry'er. An apparatus for drying the spent malt, known as brewer's *grains*, or other similarly sodden material. The illustration shows a regular plant for this purpose, consisting of a series of six cylindrical casings, with rotating paddle-shafts driven by bevel-gearing from a single shaft rotated

Fig. 2295.



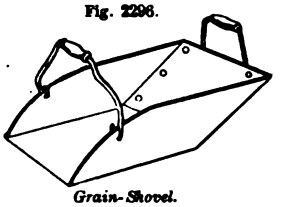
Grains-Dryer.

by power from the engine. The casings are heated by steam-pipes, and the grains pass into one end of the cylinder and out at the other, being then elevated to the upper floor, where they are sacked. Grains are dried for feed, spent hops for manure, sprouted grains for malt. A fan drives furnace-heated air through the grains, the hot vapor passing out at the upper part of the cylinder.

Grain-sep'a-ra'tor. A thrashing-machine. See SEPARATOR; THRASHING-MACHINE; GRAIN-SCREEN; FANNING-MILL.

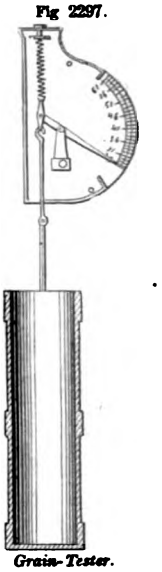
Grain-shov'el. One for handling grain in bag-

Fig. 2296.



Grain-Shovel.

Fig. 2297.



Grain-Tester.

ging, on the floor of a kiln, granary, or warehouse, or in the hold of a vessel where it is in bulk. In the example, the swinging handles are attached in positions to bring the weight of grain evenly on both hands to facilitate the shoveling of the same.

In the more usual form it is a scoop-shaped shovel.

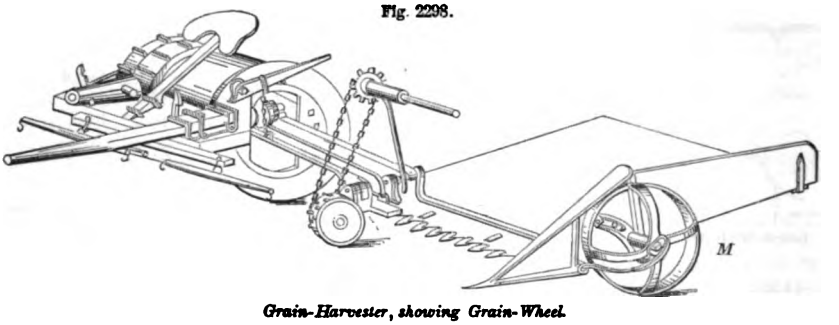
Grain-test'er. A means for weighing small quantities, as samples of grain. The cup has a known capacity, as a certain aliquot part of a bushel, and the divisions on the scale indicate the pounds which a bushel of the grain tested would weigh.

Grain-thrash'er. A machine for operating on grain in the sheaf to remove it from the straw. See THRASHING-MACHINE.

Grain-tin. Crystalline tin ore. Metallic tin smelted with charcoal. Tin reduced from the loose grains of tin stone.

Grain-wheel. (*Husbandry.*) The wheel *M* of

Fig. 2298.



Grain-Harvester, showing Grain-Wheel.

a harvesting-machine which supports the outer end of the finger-bar.

Graip. A manure or potato fork.

Gran'a-ry. A bin or house for storing thrashed grain.

In the cradle of civilization, Egypt, the granaries were on a costly and unsurpassed scale. They consisted of buildings in which the bins were arranged in a double row of brick structures, like ovens.

These were probably of adobe, and had two doors; an upper one through which they were filled, and a lower one through which the grain was removed. They were ascended by steps, as shown in the illustration, which is from a painting in the tomb of Rotei at Beni Hassan. The grain is measured and noted by attendant clerks, as shown in another painting.

Demosthenes tells us that, of the whole foreign importation of grain into Attica, one half came from the Scythians of the Euxine, and estimates its amount in ordinary years at 400,000 medimni = 600,000 bushels. The fertility of the soil and the habits of the people remain nearly the same, and the trade of England with Odessa, at the present time, is a counterpart of that which twenty-three centuries ago was carried on between Athens and the Scyths of the Pontus.

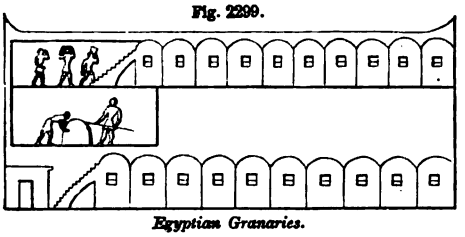
"The Greeks in former times [STRABO, A. D. 16] imported from the Chersonesus corn and the cured

Digitized by Google

fish of Palus Mæotus. Leucon is said to have sent to the Athenians 2,100,000 medimni of grain from Theodosia (a town)." A medimnus was about 1½ bushels, English.

A Sicilian bushel of wheat in the time of Polybius (150 B. C.) was worth, in Cisalpine Gaul,

Fig. 2299.



Egyptian Granaries.

Lombardy, and Piedmont, 4 oboli per bushel, barley 2 oboli. The obolus was about 3 cents.

The tavern price there for a good meal was ½ obolus.

The granaries of the Romans were of several kinds, and were enumerated at 327. One kind was a building with heavy brick walls, and a hole in the roof through which it was filled. Another was a structure raised on wooden columns.

In Thrace, Cappadocia, Spain, and Africa, grain was laid up in pits lined with chaff. Caverns and cisterns were used in Palestine. A similar practice yet prevails in Tuscany.

Grand-ac'tion. A piano-forte action, in which three features are combined: 1, a *hammer* to strike the string; 2, a *hopper* to elevate the hammer, and then escaping therefrom leave the latter instantly to fall away from the string, independently of the position of the key; and 3, a *check* to catch the hammer and prevent rebounding.

Grande. (*Sugar Manufacture.*) The largest evaporating-pan of a battery.

Grand-pi-a'no. A harp-shaped piano, whose form is suggested by the varying lengths of the strings, the mechanism being introduced in the most effective manner regardless of the dimensions of the instrument, as in the square or cottage, where the motions are incommoded to bring the instrument within certain limits or proportions. See PIANO-FORTE.

Certain piano-forte movements are invented for and known as grand-actions.

The grand-piano has three strings to each note.

The *bi-chord* or *semi-grand* has but two strings to a note, but has the *grand* movement. The *cottage* or *boudoir* grand has shorter strings, and is less bulky.

The *grand square* has the movement of the grand in a square case.

The *upright* grand was set on end, and, being unwieldy, was superseded by the *cabinet*, in which the frame came down to the floor, long vertical rods transmitting the movement of the keys to the upper ends of the wires.

Gran'ite. A hard and durable silicious stone composed of quartz, feldspar, and mica conglomerated.

Gneiss has similar components, but is stratified.

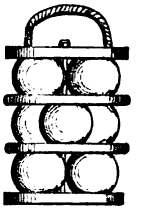
Gran'ite-axe. (*Quarrying.*) A stone axe for spalling granite.

Gran'ny's Knot. (*Nautical.*) A knot in which the second tie is across, differing from a reef-knot, in which the end and outer part are in line. See KNOT.

Gran'u-la'ted-steel. (*Metallurgy.*) Melted pig-iron is scattered by a wheel into a cistern of water, and thus reduced to fragments. These are imbedded in powdered hematite or sparry iron ore, and subjected to furnace heat. The exterior of the fragments become decarbonized, and thus reduced to the condition of malleable iron. The metal is made homogeneous by melting, and steel is produced.

Grape-shot. Spherical iron shot rather less than half the diameter of the bore of the piece for which they are intended, and put up in *stands* consisting of three tiers of three shot each; the stand has a circular cast-iron plate at top and bottom connected by a bolt and nut; two rings bind the tires together and keep them in place. Grape-shot are now little used, except with guns of the larger calibers, from 24-pounders upwards.

Fig. 2300.



Grape-Shot.

Quilted grape are formed by sewing the shot up in a sort of canvas bag, which is afterwards wrapped around with twine or cord, so as to form meshes; musket bullets put up in this way were formerly employed for blunderbusses, wall-pieces, and small artillery.

Grape-trel'lis. A structure on which grape-vines are trained. See TRELLIS.

Previous to 1547 (time of Edward VI.) grapes were brought from Flanders to England. The vine was introduced into England in 1552. The statements of the growth of the vine in Britain (time of Julius Cæsar) seem to lack confirmation. One of the largest vines in Europe is that of Hampton Court Palace, near London, the famous palace built by Cardinal Wolsey and given to Henry VIII. It is stated to have been planted in 1769, and to have produced 2,272 bunches of grapes in a season, weighing over 2,000 pounds; its stem being thirteen inches in girth.

Graph'ic-mi'cro-scope. A microscope provided with a reflector, which casts down the image upon a sheet of paper. The instrument has two reflectors, the second one of which is a prism, across the edge of which the eye observes the image, which may be traced by a pencil.

Graph'ite. A form of carbon occurring in nodules or foliated six-sided prisms, and used for pencils, for blacking stoves, for crucibles, and for lubricating. Graphite was supposed by the early chemists to be a carburet of iron, but it is now universally acknowledged that iron is only mechanically mixed with it, there being no chemical combination between them. It may have a trace of iron, but this is not essential. Its name, *graphite*, is derived from its use in writing and drawing. It is well known in the mechanic arts as *plumbago* and as *black-lead*, but the names have no relevance, as *plumbum*, lead, is not found in it.

It is a unique mineral, useful for many and widely different purposes in the mechanic arts. It was utilized as a lubricator in the immediate neighborhood of its natural deposits two hundred years ago, but was not widely used till within the past few years. It can hardly be exceeded as a lubricator, when finely pulverized, perfectly pure, and free from grit, — conditions which are absolutely necessary for this use. It has been mixed with clay for crucibles since the tenth century, but was not generally adopted till the foliated variety was utilized, in 1827, by an American, — the late Mr. Joseph Dixon of Jersey City. It was early adopted for crayons, and was found in use by the Aztecs when Cortez landed in Mexico. It is indispensable in the graphic arts, in the form of what are commonly called *lead-pencils*, the finest of which were formerly made in England from the granulated, pure graphite, taken from the celebrated Borrowdale Mine in Cumberland; but after that mine became exhausted the world was supplied with pencils made from the impure graphite found in Bavaria and Bohemia, purified for the purpose. Bavaria is well represented by the Messrs. Faber, whose pencils of all qualities are so well known. But recently the fine graphite found at Ticonderoga, in the State of New York, has been utilized for this purpose by the Dixon Crucible Company of Jersey City, and a fine quality of pencils produced, — the company having been awarded the Medal of Progress for them by the Vienna Universal Exposition, 1873.

Graphite is polymorphous, has a bright metallic luster, of a steel-gray color, something like that of molybdena, but darker, and the two are sometimes confounded by inexpert persons, both being sometimes formed in flexible laminæ; but the molybdena has none of the physical characteristics even of foliated graphite, except the similarity of color and form.

Molybdena has a sp. gr. of about 4, which is about double that of graphite. Nitric acid attacks molybdena, reducing it to a yellow powder, but does not affect graphite. Molybdena gives a yellowish green flame with the blow-pipe; graphite does not. Graphite in the blow-pipe flame burns away to carbonic acid, leaving but little ash, and, if pure, develops no odor. Molybdena deflagrates with niter much more violently than graphite. The formation of graphite most common in the pure state is that of laminated crystals, elongated at right angles with the sides of the vein, if not more than from four to six inches wide; but when the vein widens, the crystallization often radiates from numerous centers, and the whole formation is very beautiful; the foliated variety is equally valuable and more brilliant, but rare in any quantity; the acicular form of crystal is not apt to be as pure in the lump, but is useful for most purposes; the granulated variety, the purest of all, is of little use for crucibles, but, with suitable manipulation, produces the finest grades for electrotyping and fine lead-pencils, and is unequaled for lubricating. Pure graphite is absolutely free from grit, when pulverized and rubbed between the fingers, and the polish produced in the same way is instantaneous and very bright, being like a darker shade of polished silver. It is also found mixed with iron, rhombspar, and other forms of lime, the rock and earth in which the vein is carried, and many other foreign substances injurious for all the purposes for which pure graphite is needed. Lime, for instance, is fatal to graphite for crucible making.

It is very refractory in closed vessels, but combustible in air or oxygen at a high heat. It is infusible. The laminated and foliated varieties are difficult to pulverize, reducing to scales instead of grains, and if it is wanted very finely divided must be ground in water.

It is found in these varieties mainly in Ceylon, where it occurs in veins, carried in rock and kaolin; the lumps are removed and sent to market as they are, not being entirely pure, but sufficiently so for most purposes. It is found in many of our own States and in Canada, in veins and disseminated in quartz and other rock, from which it is separated by stamping in water and floating off the scales; but while this process, with care in the manipulation, produces the purest graphite for use in the arts, it has not so far been successful except at Ticonderoga, by the American Graphite Company. A large deposit of the granulated graphite was supposed to have been found in California, and a favorable report was made upon it by one of the European savants, but there is no real graphite in the mixture; it is a sort of carboniferous clay, deceptive in its physical characteristics. A good, compact, granulated graphite is found in Sonora, Mexico, and a specimen brought to us from Japan is of the same character; but the granulated graphite best and longest known to commerce is found in vast quantities in Bohemia and Bavaria. It is divided in water and floated, to separate it into grades, not being pure enough as it comes from the mines. It is cheap in price, but poor in quality for use in the arts, except for pencils after extensive purification. It is not very refractory, and is of but little use for crucibles, although long employed for want of better. It is useless for polishing, or for preservative paint, or for lubricating, and, having a very low conducting power, cannot be used to advantage for galvanoplastics. It resembles a weak, black clay in appearance, and has but two of the physical characteristics of true, natural graphite, these being the marking and the greasy feel when highly purified. There are large deposits of compact granulated graphite in Siberia, but they are so far from any means of transportation that only the deposit discovered by Mr. Alberti has as yet been made use of, and that is under contract to the Messrs. Faber of Stein, Bavaria, for pencils.

Natural graphite has a sp. gr. of 2.089 – 2.245. Artificial graphite forms on the inside of furnaces

Digitized by Google

and retorts where coal is used for making gas; but it is so hard and harsh that it is not adapted to many uses, and has been utilized only for carbons for galvanic batteries by sawing it into the required shape. Graphite occurs in the primitive and frequently in the transition rocks, in granite, gneiss, quartz, feldspar, kaolin, mica-slate, schist, crystalline limestone, and occasionally in the coal formations. It is generally in veins, but in the quartz it is often in disseminated scales. In Ceylon it is in well-defined veins. In the United States and Canada it occurs in irregular veins and in nests, patches, and pockets, the only reliable veins known being those of the American Graphite Company at Ticonderoga, New York.

Graphite is the purest carbon next to the diamond, but requiring a higher heat to burn it, and leaving a reddish ash if the specimen contains a trace of iron, as most of it does. It is not affected by acids or alkalies. If the well-known process of washing is not sufficient to purify the graphite to the required degree, then either of the following methods may be adopted.

Method of Professor Kerl of the Royal School of Mines, Berlin. Heating to a red heat in a retort will change the iron oxide into metallic iron, and sulphate salts into sulphides of metals, for the extraction of which employ hydrochloric acid.

Professor Loewe heats the graphite to a red heat, with double the quantity of carbonate of potash, soda, or hydrate of potash; he extracts the formed potash salts, especially the silicate of potash, with boiling water, heats the residue gently with dilute nitric or strong hydrochloric acid, filters, and washes out with water and dries. Repeating this process three times yielded an entirely pure graphite.

Professor Brodie obtains a graphite almost pure, 99.96 carbon, by boiling graphite with acid, and heating with hydrate of potash. If the graphite is pulverized, mix it with ¼ of its weight of chlorate of potash, and double the weight of the graphite of concentrated sulphuric acid; heat the mixture in a water-bath; a little fluoride of sodium is added to remove silica, and the whole carefully washed, dried, and heated to a red heat.

Graphite may also be purified sufficiently for most uses by treating it with 4 parts sulphuric and 1 part nitric acid, washing and drying. See CRUCIBLE; PENCIL.

These points are taken from the manuscript of a work on graphite, now in course of preparation, by Orestes Cleveland, President of the Dixon Crucible Company, of Jersey City.

Graph-om'e-ter. A surveying instrument for taking angles. A *demicircle*.

Graph'o-type. A process invented by Hitchcock, in which a zinc plate is covered with a thick coating of oxide of zinc, placed under an hydraulic press to made a perfectly plain and hard surface, the design drawn upon the oxide with an ink consisting of a chloride of zinc and a menstruum. This produces as to the parts where the ink touches a very hard material, the oxychloride of zinc. The remaining surface is rubbed away by brushes, velvet, and the fingers, leaving the lines in relief to be printed from.

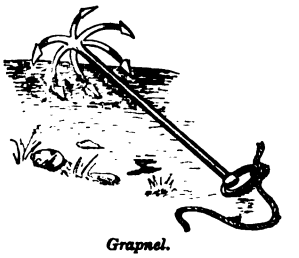
The process is more used in England than in this country, though it is an American invention. The English illustrated paper, the "Graphic," is understood to be largely illustrated by this means.

In one form of the process the adhering material is solidified by immersing it in a solution of silicate of soda.

Grap'nalls. A heavy tongs used for dragging logs, chunks, stones, etc. See GRAPPLE.

Grap'nel. 1. A small anchor having five or six hooks arranged in a circular manner on the end of the shank, which terminates in a ring to which the cable is attached. It is used by small vessels and boats, and sometimes as a kedge in warping or hauling.

Fig. 2301.



Grapnel.

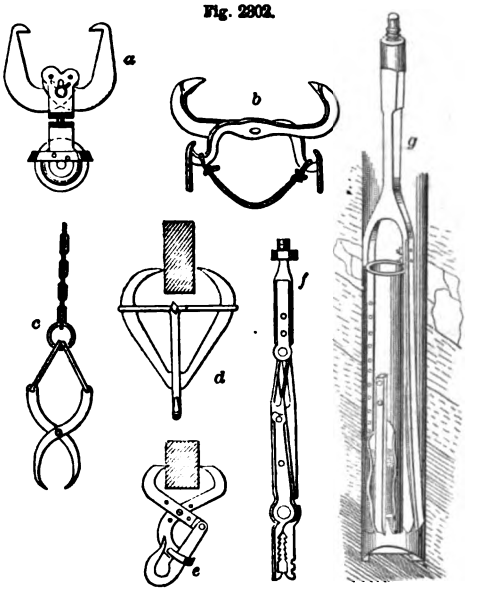
2. An implement for recovering tools, etc., dropped into a bored shaft; or for breaking and raising the axial stem left by the annular borer. See GRAB; GRAPPLE.

Grap'ple. 1. A hook for securing one vessel to another or one object to another. Used in holding vessels in engagement while boarding, or in a more peaceable way to hold them associated while loading, unloading, or transferring cargo. A *grappling-iron*.

2. A grasping tongs, used in various shapes and for many purposes.

a is a form used to grasp on each side of a rafter or beam to form a means of suspending hay-hoisting

Fig. 2302.



Grapples.

tackle. The claws form a toggle which is clasped against the wood by the weight suspended from the sheave.

b is somewhat similar, the claws being moved in by the weight suspended from the bight of the cord.

c is for ice-tongs or clutching other objects to be lifted.

d has a pair of toggle-bars jointed to the claws.

e is a toggle-clutch.

f has claw-ended levers for reaching tools dropped into or broken in bored wells.

g is a *grab* for recovering well-tubes from bored wells or shafts.

Digitized by Google

Grass-cloth. A light fabric resembling linen, exported from the Malay Islands. It is made from the fiber of the "poa," a species of nettle.

A similar cloth is made from the Chinese *ma*, a species of *cannabis* (hemp). It is perennial, and sends up numerous stems of from 7 to 10 feet in hight.

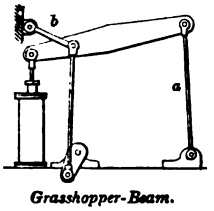
The plant yields three crops every year. The first cutting takes place in June. On being cut, the leaves are carefully taken off with a bamboo knife by women and children, generally on the spot. It is then taken to the house and soaked in water for an hour. In cold weather the water should be tepid. After this the plant is broken in the middle, by which the fibrous portion is loosened and raised from the stalk; into the interstice thus made, the operator, generally a woman or child, thrusts the finger-nails and separates the fibers from the center to one extremity and then to the other. A partial bleaching is effected on the fibers before they undergo farther division, sometimes by boiling and at other times by pounding on a plank with a mallet. After being dried in the sun, a tedious process of splitting the fibers by the finger-nail ensues, then hatcheling, followed by rolling in balls, soaking, washing, and steeping in lye. The fibers are then spliced for the weaver.

Grass-edg'ing Shears. A form of large scissors with a bent shank, and used for cutting the straggling leaves of grass at the edges of grass-plots and of grass-bordered beds.

Grass-har'vest-er. See MOWER.

Grass'hop-per-beam. One form of working-beam used in steam-engines. Instead of oscillating in fixed bearings, one end is attached to a rocking pillar *a*, and the point of attachment of the pitman to the beam bears such relation to that of the piston-rod as will correspond to the relation between the stroke of the piston and the throw of the crank. *b* is the radius-bar of the parallel motion which secures verticality to the piston-rod.

Fig. 2303.



Grasshopper-Beam.

Grass'ing. The exposure of *steeped* flax-straw on the grass, where it is spread evenly and frequently turned to wash out the mucilage and loosen the *shives* and *boon*. Then follows *breaking*.

Grass-seed Sep'a-ra'tor. A form of sifter by which grass-seed is rid of larger and smaller matters, either grains or weed seeds, as the case may be. It may have several sieves, with wire-cloth of varying fineness, the more open to allow the grass-seed to pass and remove larger matters, and sieves with closer meshes to hold the grass-seed and allow certain small weed-seeds and dust to pass.

Grate. 1. A grated box or basket, or a box with a series of bars for a floor, in which fuel is burned.

The oldest form of grate may have been a row of bars laid upon bearers or stones so as to admit air beneath the fuel in the intervals of the bars. A *cresset* or *fire-cage* is also an old form of grate. See CRESSET.

In an inventory, dated 1606, of the goods of Sir Thomas Kytson, at Hengrave Hall, Suffolk, England, mention is made of "a cradell of iron for the chimnye to burn sea-coal with," and also "j fier sholve made like a grate to seft the sea-coal with." The "cradell" was probably a standing basket-grate. This is an early mention of the use of sea-coal, but the basket form was common in cressets.

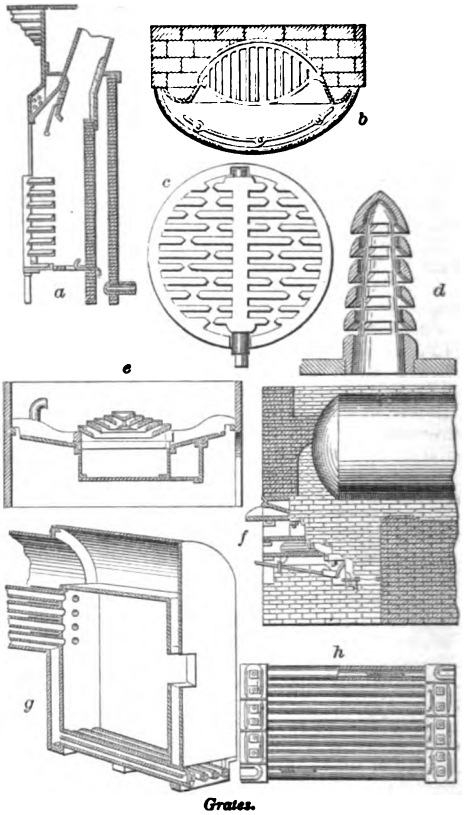
James Watt, in 1785, patented an arrangement for consuming the smoke in furnaces, by supplying the fire from above downward by means of a reservoir of fuel in contact with the ignited mass, the fuel descending by its own weight to supply the consumption.

Combustion was supported by a strong lateral current of air passing through the fire to a flue on the other side, near the entrance of which was a supplementary fire which consumed the smoke of the first.

Cutler patented a smoke-consuming contrivance for open fires in 1816, and in 1817 Deakin attached a metallic box, holding fuel for one day's consumption, to the back of the fireplace; the fuel was drawn forward horizontally by a screw, as required, and in this way the smoke was nearly all consumed.

In the same year Hawkins patented a shovel for supplying coal to the fire at bottom. The shovel had a cover, and the contained coal was pushed forward into the fire by a piston.

Fig. 2304.



Grates.

The revolving grate was introduced by Steel and Brunton, English patents, about 1819.

Grate-bars of hollow tubes, connecting water-boxes at front and rear, were introduced by Chapman in 1824. See SMOKE-CONSUMING FURNACE.

In 1825, Atkins attached a fuel-chamber to the back grates, the bottom of the chamber being made to slope at a considerable angle.

Jeakes, in 1854, formed a movable grate, which was lowered into the fuel-box, gradually consuming

Digitized by Google

the fuel and admitting a supply of air from above to support the combustion.

Rowe, in 1854, introduced coal into the bottom of the grate by a pipe leading from a side reservoir of fuel.

In 1854, Bachhoffner consumed the smoke of one fire by passing it through an upper fire.

Leighton, in 1856, surrounded the sides and back of a fire-grate with a fuel-chamber, the fuel being brought forward by a poker, as required. The outer coal is thus coked. See also FIREPLACE.

Grates are known by many names indicative of position, as *low-down;* purpose, as *steam-furnace* grate; construction, as *revolving, shaking,* etc. Fig. 2304 shows some forms, in which —

a is the ordinary basket-grate of the parlor fireplace.

b is the low-down grate as viewed from above, the wall in section.

c is a stove-grate, in which the central oscillating portion has alternately long and short bars, which act in conjunction with others projecting inward from the ring, the ends of each being deeper as more exposed to wear.

d is a cone-shaped or pyramidal grate opened at its bottom, intended to be placed in the center of a fire-pot in a stove. The bars of these grates are inclined downwards from the center to the outside, so as to prevent the fire-coal, sawdust, tan, etc., which it is intended to burn, from choking up the apertures in the grate.

e is Eaton's locomotive furnace-grate. The congeries of grate-bars are in steps, and afford more uniform access of air to the fuel. The ash-pan has back and front dampers, and a perforated guard-plate in front to govern the draft.

f is composed of three or more tiers, in combination with a fire-box and trap-grate. When in use, a continuous inclined plane of incandescent coals is formed from the upper tier to the lowest grate.

g is a steam-boiler furnace. The grates are tubular, and have longitudinal horizontal diaphragms extending nearly throughout their length, forming an extension of the boiler-surface in which the water circulates.

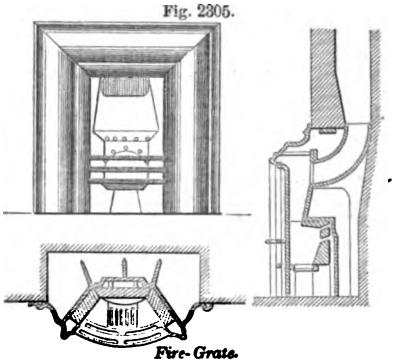
In *h* the tubes are combined into a continuous passage for the water, the alternate ends being connected by caps which admit of expansion.

The commission appointed by the House of Commons in 1856 to examine into the best mode of heating buildings reported a fire-grate for heating barracks, hospitals, etc., which embodies many of the best features of previously existing inventions.

Fig. 2305 illustrates a grate of this kind set in an ordinary fireplace. The grate is placed as much forward in the room as possible; the part in which the fire is contained is of fire-brick; the bottom, being partly solid, checks the consumption of fuel. A supply of air is admitted from behind the grate, and is thrown on the top of the fire to assist in consuming the smoke; the sides are splayed so as to throw the heat by radiation as much as possible into the room; the opening into the chimney has no register; there is a chamber behind the grate into which air is brought from the outside and warmed by the large heating surface of the back of the grate, increased by flanges, and after being heated to from 56° to 70° F., the air passes into the room by a shaft cut out of the wall which terminates in a louvered opening placed out of reach, or a shaft of sheet-iron may be fixed to the wall to serve the same purpose. In the accompanying plan and section, the fire-brick lining of the grate is shown by the shaded portion; the back lining has grooves in it terminating in holes just at the bottom of the splay, which form air-channels for admitting air at the back over the fire. The hearth is made of a plate of cast-iron.

The contrivance for admitting air into the air-chamber depends on circumstances. If the fireplace be built in an external wall, the openings for fresh air may be made in the back; but if in an internal wall, the channel from the outside may be either between the flooring of the room and the ceiling joists of the room below, or in the spaces between the joists, or by a tube or hollow beam carried below the ceiling of the room below.

Fig. 2305.



Fire-Grate.

The subject may be pursued under a variety of heads, where allusion may be found to heating and ventilating devices. See FURNACE; VENTILATOR, etc. Also specific indexes under AIR-APPLIANCES; STOVES AND HEATING-APPLIANCES, etc.

2. (*Mining.*) A metallic perforated plate on which ores are stamped.

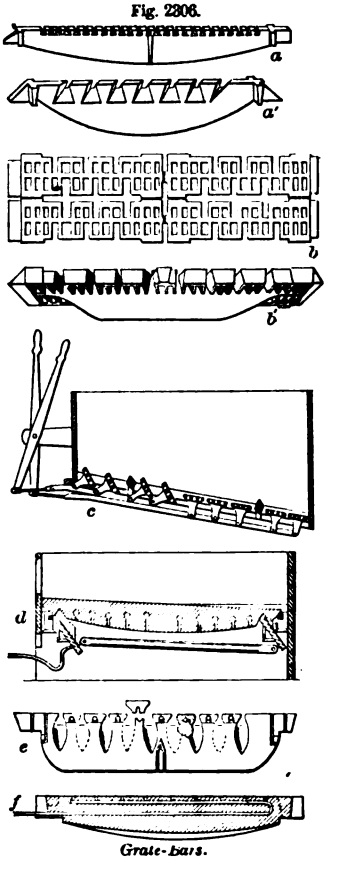
Grate-bar. The iron bar in a furnace which supports the fuel. A part of a grid in a furnace.

Among the numerous forms may be cited: —

a a', the *paragon*-bar, which has passages for air formed by notches in the upper surface expanded downwardly, so as not to fill with ashes.

b b' are two views of a grate-bar. The upper view is a top view of two bars; the lower one

Fig. 2306.



Grate-bars.

Digitized by Google

shows a side and bottom view, with a strengthening belly flange.

c is an inclined shaking grate composed of a number of bars, with lozenge-shaped openings, cast in one piece, and so arranged as to be operated in pairs or all at once, by levers. The bars are placed at right angles with the length of the grate; the air supplied to them from beneath flows through their perforated tops, which rise above the surface of the grate, and among the burning coals.

In *d* each alternate bar is supported by the imposition of its inclined edge upon the oblique surface of the cross-bars at either end. When the rock bars are moved, they strike against the notches and cause one end of the grate-bar to climb upon the supporting bar, while the other end slides down the incline of the supporting bar at that end.

e has spaces between the fuel points which admit air to the incandescent fuel, and afford an escape for dust and ashes from the fire-bed. Provision is made for economically renewing the fuel points, and the construction is such as to afford a proper grate surface, with a copious supply of air.

f has a steam-pipe passing longitudinally through the grate-bar and throwing jets of steam from its upper surface.

These are but a few of the numerous kinds.

The grate surface should be equal to one square foot for each horse-power.

Grat'er. 1. A plate roughened by punching holes which raise protuberances forming a rasping surface. Used for grating ginger, nutmeg, horseradish, lemons, crackers, etc.

2. (*Bookbinding.*) An iron instrument used by the forwarder in rubbing the backs of sewed books after pasting.

Grate-sur'face. (*Steam-engine.*) The area of surface of grate by which air has access to the fuel.

In an average boiler this is 1 square foot per horse-power, and is expected to evaporate 1 cubic foot of water per hour.

With the Cornish boiler double this amount of grate-surface is allowed. With the locomotive, 1 square foot evaporates 8 cubic feet of water.

Grat'ing. (*Nautical.*) An open wood-work of cross slats to cover hatchways and yet admit light and air.

Grav'el-car. A railway ballast-wagon.

Grav'er. Gravers are used for engraving or chasing metals or other materials, such as fine hard woods, in certain descriptions of ornamental work. They are made of fine steel, which, for cutting steel, is tempered to a "pale straw" color, the first color that appears in "drawing the temper."

Gravers are made of different shapes. Those for "line" engraving are square or rhomboidal in their cross section, and the end is sharpened by grinding it off obliquely, as seen in the figures *a b c*. The lower edge of the graver is termed the *belly*, and is angular for line-engraving. For engraving lettering it is frequently rounded or flat, and for heavy work is destitute of a handle, and is driven by a hammer.

d shows the shape of the graver used in *stipple* or *chalk* engraving, so called from its consisting of dots which resemble the appearance of chalk-drawing upon rough paper. See STIPPLE-ENGRAVING.

e is a section of a square graver.

f is a lozenge graver.

g h i are tint tools, used principally by wood engravers.

j shows the work of a tint tool.

k shows a set of tint tools.

l is an adjustable double graver.

Grave'stone. A monumental stone for erection or erected at a grave. The advertisement by the Quartermaster-General, U. S. A., for bids for furnishing 300,000 gravestones for soldiers' graves at different national cemeteries throughout the country, brought forward specimens of all materials, — white and black marble, polished and plain, sandstone of various colors, white and red clay, vitrified and unvitrified, porcelain, cryolite porcelain, béton-coignet, and all sorts of composite stone; painted iron, malleable iron, compositions of tin and spelter, copper and spelter, brass, bronze, and wood.

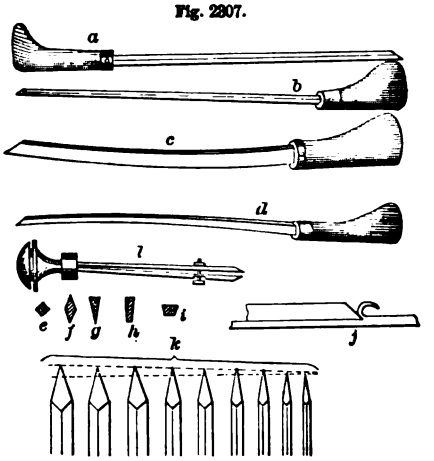
One stone from Philadelphia has letters cut by a *sand-blast* system in seven minutes.

Grav-im'e-ter. An instrument for determining the specific gravities of bodies. Nicholson's instrument consists of a hollow ball of brass or copper, having a stem rising from its top which supports a cup or dish. Another dish is suspended from the lower part of the ball by means of a stirrup; this dish is made heavy enough to keep the instrument vertical when placed in a liquid; and the weight of the instrument is such that 1,000 grains placed in the upper dish sinks it in distilled water, so that a mark about the middle of the stem is on a level with the surface of the liquid. See AREOMETER.

Grav'ing. (*Nautical.*) Cleaning a ship's bottom by burning off the sea-weed and then paying the planks with pitch. Ships were formerly beached for this purpose, and the work was done during the recess of the tide. It is also called *beaming*. See GRAVING-DOCK.

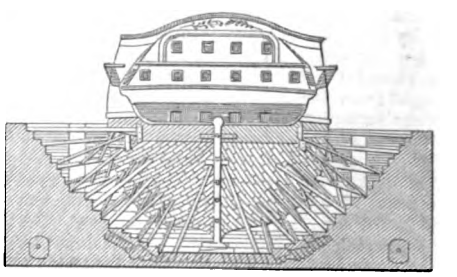
Grav'ing-dock. A dock into which vessels are floated to have their bottoms examined and cleaned. A *dry-dock*.

Fig. 2307.



Gravers.

Fig. 2308.



Graving-Dock.

Digitized by Google

The vessel is floated in and the gates at the entrance closed when the tide is at ebb. The remaining water is then pumped out.

The graving-dock of the Navy Yard at Brooklyn measures 350 feet in length within the caisson-groove, and the main chamber is 98 feet in breadth at the top. The width of entrance is 68 feet, and the depth of water 26 feet. It was commenced in 1841, and completed in 1851. Great difficulty was experienced in its execution, occasioned mainly by the softness of the foundations; upwards of 8,000 piles, varying from 25 to 40 feet in length, having been employed in the work, which is stated to have cost $2,000,000. It is built of granite, and is furnished with iron gates and an iron caisson or floating gate.

Other larger ones are now constructed at South Brooklyn.

Many of the Liverpool docks have graving-docks, and some of the dock-entrances are arranged to be used as graving-docks. Two of the latter have the following dimensions: —

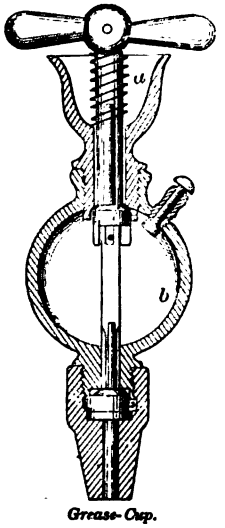
	Length.	Width.	Depth of Water at Sill. Feet.
Canada dock-lock .	500	100	26
Huskisson dock-lock	396	80	24.75
Birkenhead dock-lock	500	85	30.25
16 graving-docks of Liverpool . .	300–700	40–70	18–21
3 Birkenhead graving-docks . .	750	50–70	25.75
10 private graving-docks, Birkenhead	380–440	80–87	19.25–24

Grav'i-ty-bat'ter-y. Invented by Callaud or by C. F. Varley, London; English patent, December 5, 1854, no. 2555. A form of double-fluid battery, in which the fluids range themselves at different hights in a single jar by virtue of their different specific gravities. The copper or − element is in the bottom, and the zinc or + in the upper part of the cell. See CALLAUD BATTERY.

In the ordinary forms of "gravity" or "Callaud" battery, if the sulphate of copper dissolves faster than its solution is used up, the copper solution rises, finally touching the zinc, rendering the battery useless.

R. M. Lockwood, patent April 8, 1873, shows an arrangement for avoiding this. The copper element or a portion thereof is placed at the point where it is desired to maintain the separation of the liquids; so long as the circuit is closed the copper solution will not rise above such element.

Fig. 2309



Grease-Cup.

Grease-box. (*Railroad Engine.*) The receptacle over an axle arm, which contains the lubricating material.

Grease-cock. (*Machinery.*) A faucet by which oil is admitted to a journal-box, or other part requiring lubrication. It is used on the cylinder cover for lubricating the piston without permitting the escape of steam or the entrance of air.

Grease-cup. (*Machinery.*) A cup attached to a part requiring lubrication, and from which it is supplied with oil. In the example, the two valves are on the same stem a little more distant apart than are their seats; the revolution of the stem by bringing one or the other of the valves to its seat establishes communication between the supply cup *a* and the globe *b*, or between the latter and the valve-chest. See OIL-CUP.

Grease-pot. An iron pot, the third in the series in which iron plates are tinned. It contains clear melted tallow or lard, and is situated between the *wash-pot* and the *pan*. The series is: *tin-pot, wash-pot, grease-pot, pan*, and *list-pot*. See TIN-PLATE.

Great-or'gan. (*Music.*) One (and the most important) of the three organs which are associated in large combined organs. They are the *great*-organ, the *choir*-organ, and the *swell*; to which may be added the *pedal*-organ or *foot-keys* for acting on the larger pipes. The key-board of the *great*-organ contains the principal keys, and has the middle position, the *swell* having the highest bank and the *choir* the lowest. See ORGAN.

Great Prim'er. (*Printing.*) A type four sizes larger than *Long Primer*.

Long Primer, 89 ems to a foot.
Small Pica, 83 ems to a foot.
Pica, 71 ems to a foot.
English, 64 ems to a foot.
Great Primer, 51 ems to a foot.

Greek-fire. An incendiary composition used in early times by the Tartars, and afterwards by the Greeks.

The invention is ascribed to Collinicus, an architect of Heliopolis, the "city of the sun," afterwards called Baalbec. He is reported to have deserted the service of the Caliph and entered that of the Emperor Constantine Pogonatus, A. D. 673. The Emperor Leo described its use, 911; the Princess Anna Comnena described its properties, 1106; so did Joinville, 1249.

In two sieges, writes Gibbon, the deliverance of Constantinople may be chiefly ascribed to the novelty, the terrors, and the real efficacy of the Greek-fire. It was poured from large boilers on the ramparts, or launched in hollow balls of metal, or darted with arrows and javelins, twisted round with flax and tow which had imbibed the inflammable oil. In naval battles, fire-ships filled with these combustibles were carried by the wind, that fanned their flames against the sides of the enemy's vessels. It was usually blown through long copper tubes, planted in the prow of a galley, and fancifully shaped into the mouths of savage monsters that seemed to vomit a stream of liquid fire. The art of compounding it was preserved at Constantinople as the palladium of the state. Its galleys and artillery might occasionally be lent to the allies of Rome, but the secret of the Greek-fire was concealed with the most jealous scruple for above four hundred years. The Princess Anna Comnena, in mentioning resin, sulphur, and oil as its components, only intended, it is probable, to baffle curiosity by telling just so much as everybody knew already.

In 1098, the fleet of Alexis Comnenus used Greek-fire against the Pisans. His ships had "siphos" fore and aft, in form of syringes, which squirted the inflamed matters.

It is believed that the ancient Byzantium was marked by the present walls of the Seraglio. Con-

Digitized by Google

stantine enlarged it A. D. 328, gave it its name, and made it the rival of Rome. It was taken from the Greeks, in 1204, by the Venetians under Dandolo; retaken by the Greeks, in 1261, under the Emperor Michael Palæologus; captured by the Turks in 1453.

An old recipe for Greek-fire is thus given: —

"Asphaltum, nepta, dragantum, pix quoque Græca,
Sulphur, vernicis, de perollo quoque vitro,
Mercurii, sal gemmæ Græci dicitur ignis."

Another reads as follows: "Take of pulverized resin, sulphur, and pitch equal parts; one fourth of oppopanax and of pigeons' dung well dried, dissolved in turpentine water or oil of sulphur; these put into a strong, close, glass vessel and heat for 15 days in an oven; after which distill the whole in the manner of spirits of wine and keep for use."

The contact of water would increase the violence of this villainous compound.

The savans of the Middle Ages were well acquainted with a number of explosive mixtures, some of which were especially effective by the liberation of poisonous gases which asphyxiated the enemy. In effect like our modern stink-balls, but not thrown, like the latter, from a gun or mortar, but projected by squirts or in bottles, after the manner of a hand-grenade. Prester John, who seems to have combined regal and sacerdotal powers somewhere in Tartary about the eleventh century (some say the thirteenth), is cited as particularly skilful in blowing up his enemies. He stuffed — so says the legend — copper figures with explosive and combustible materials which were emitted at the mouths and nostrils of the effigies, making great havoc.

The Danish historian, Saxo Grammaticus, A. D. 1200, gives an account of a similar contrivance, used by a Gothic king. The devices of Archimedes, who defended Syracuse from the Romans, 212 B. C., were mechanical or optical, and do not seem to have involved chemical compounds.

Green-house. 1. (*Pottery.*) A house moderately warmed, where some kinds of *green-ware* are placed to become partially dried before taking to the *hot-house*, where the drying is completed by strong heat.

The ware is then arranged in seggars and *fired* in the kiln.

2. (*Horticulture.*) A plant-house, with glass roof and sides, with facilities for maintaining an artificial temperature and the necessary ventilation.

Gre'go-ri-an Tel'e-scope. The first and most ordinary form of reflecting telescope, invented by Professor James Gregory of Scotland, and described by him 1663.

Its object mirror or speculum is perforated in its axis, and reflects the image to a smaller concave speculum placed in the axis of the tube at a distance from the larger speculum. The image is viewed through an eye-piece in the aperture of the object-speculum. See TELESCOPE.

Gre-nade'. (Italian *grenado.*) A small shell weighing about two pounds, and thrown by hand. It is said to have been first used at the siege of Wacklindonck, near Gueldres. The right company of each battalion was formerly composed of the taller men armed with hand-grenades. Hence the term *grenadiers.* Various forms of grenades have been invented, some containing combustibles, missiles of various sorts, Greek-fire, or other incendiary compounds. 6-pounders, and even larger shells, have been used as rampart grenades, being rolled over parapets against assailants.

The Orsini grenades, with which an attempt was made to assassinate Louis Napoleon, were spherical shells containing powder and missiles, and having a large number of cones or nipples, each capped with a gun-cap. They were made in London.

Gren'a-dine. (*Fabric.*) A gauzy dress goods, silk or wool, plain, colored, or embroidered.

Grid. 1. A gridiron.

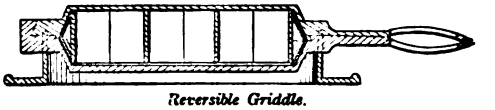
2. A grating of parallel bars, for a furnace, stove, window, vault-cover, or sewer opening.

3. A grating. Used as a concave, partially enclosing the toothed cylinder of a thrashing-machine, or the scutching beater of a cotton-batting machine. *Grids* have other uses; their essential feature of construction consists in having alternating bars and spaces, the latter afford space for the escape of matter or the passage of air.

Grid'dle. 1. A miner's sieve for separating the ore from the *halvans.*

2. A flat plate of iron long known as the *gurdel*, and used from remote antiquity for cooking flat cakes of dough upon a fire on the hearth. We find mention of the use of this implement in all histories, in the Bible, and among the classic writers, and in the Egyptian paintings. A bag of oatmeal and a *gurdel* was the ordinary furnishing of a Scottish soldier in the time of Edward III. The equipment of the Goths was substantially the same.

Fig. 2310.

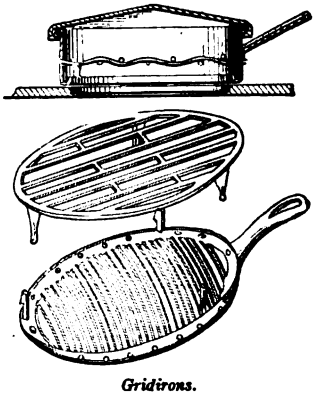


Reversible Griddle.

In the example, two dish-shaped cast-iron plates have projecting ears, and when placed together form a hollow dish to contain nests for cakes, etc. The griddle is supported by its projecting ears, which form journals whereby it is turned over upon a rim placed upon the pot-hole of a stove or range.

Grid'i-ron. 1. (*Hydraulic Engineering.*) A grated frame on which ships are hauled out of the water for examination, cleaning, and repairs. Or a framing of cross-timbers which receives a ship with the falling tide.

Fig. 2311.



Gridirons.

2. (*Domestic.*) A grated iron utensil on which fish, flesh, and fowl are exposed for broiling. The illustrations show a gridiron with a wire grating and a sheet-metal rim and cover; one with legs, and another griddle-shaped. See also BROILER.

Grid'i-ron-pend'u-lum. A compensation pendulum invented by Harrison. The bob is supported by parallel bars of two metals which are unequally expanded by heat. These are so disposed that, while one tends to lengthen it, the other tends to shorten it. The ratio of lengths is determined by the relative expansibility. See PENDULUM.

Grid'i-ron-valve. (*Steam-engine.*) A valve whose opening is divided into a number of narrow parts by which the travel may be abridged.

Digitized by Google

Griff. (*Weaving.*) A series of horizontal parallel-edged bars, also known as *knives* or *blades*, arranged in a reciprocating frame to raise and lower the vertical hooked rods connected to the *shedding* mechanism, when the hooked ends of said rods are brought by a pattern device within the path of said knives.

Gril'lage. (*Hydraulic Engineering.*) A structure of sleepers and cross-beams forming a foundation in marshy soil for a pier or wharf.

Grind'ing and Pol'ish-ing Ma-te'ri-als. Abrasive substances used in the solid form: —

Grindstone.
Hone.
Oil-stone.
Charcoal.
Emery-cake.
Fish-skin.

Abrasive substances used in powder; materials stated in about the order of their hardness: —

Diamond.
Sapphire.
Ruby.
Corundum.
Emery.
Sand.
Flint.
Glass.
Tripoli.
Turkey-stone dust.
Rottenstone.
Slate.
Pumice.
Chalk.
Oxide of iron, colcothar.
Crocus or rouge.
Oxide of tin or putty-powder.

The abrasive powders are applied by thin circular disks, which cause them to act as *saws*.

On the periphery of wheels which act as *grindstones*, *glazers*, or *buffs*, according to the quality of the material and the terms of the trades.

On plane surface of disks which form *laps*.

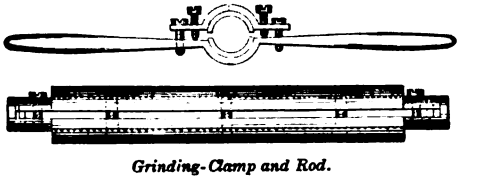
On the ends of rods which act as *drills*.

On slips of wood which act as *files*.

Spread upon cloth, paper, or leather, forming a grinding or polishing paper or pad, as the case may be. See EMERY-PAPER; SAND-PAPER; etc.

Grind'ing-clamp. A grinding-clamp for cylindrical work has two semi-cylindrical leaden blocks enclosed between the two halves of the clamp, which

Fig. 2312.



Grinding-Clamp and Rod.

are adjusted by binding-screws. The halves of the clamp are adjusted to the desired distance, slips of wood being placed in the jaws while the melted lead is run in to form the cheeks.

For internal work the grinder consists of two semi-cylindrical rods of iron, fitted to each other by dowel-pins and set screws, so as to be expanded to the required distance. The leaden cheeks are cast upon the rods, which are placed in a mold for that purpose.

Grind'ing-frame. An English term for a cotton-spinning machine.

Grind'ing-ma-chine'. Fig. 2314 shows a machine in which the article to be ground is moved past the face of the grindstone, which is stocked in a swinging frame for the purpose of giving to the bezel of the tool or implement a concave form, having a greater radius than that of the stone.

Fig. 2314 shows Whitelaw's machine for grinding pulleys. *a* is the grindstone, which is caused to revolve at about 180 turns a minute in one direction, while the pulley *b* rotates at about 130 revolutions per minute in the other.

The pulley is caused to traverse back and forth across the face of the stone by bevel-gearing connected with the crank-shaft *c*, and is kept up to the stone by similar gearing from the shaft *e*, operating the screws *d d d*, through the hand-wheel *f*.

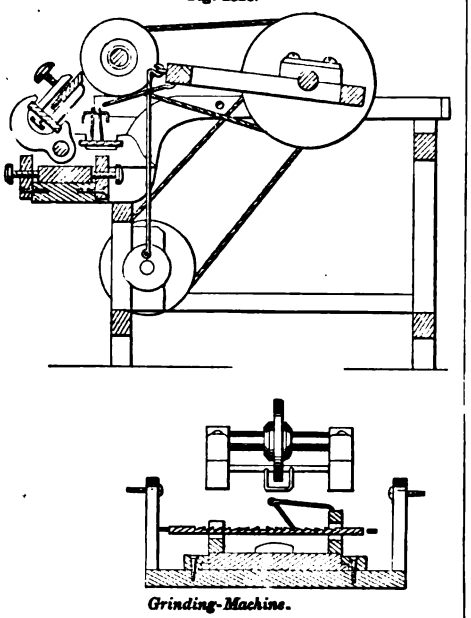
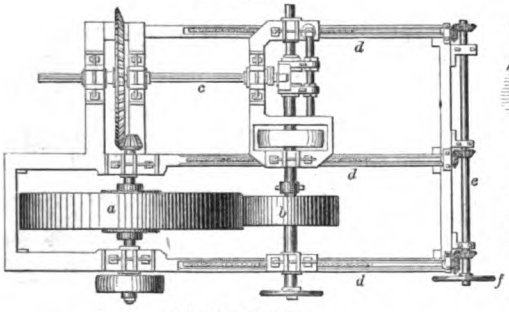
Fig. 2313.



Grinding-Machine.

Grind'ing-mill. 1. The original grinding-mill was a mortar; a hollowed stone in whose depression the parched grain was pounded by a bowlder. Such

Fig. 2314.



Grinding-Machine.

stones are found amongst most nations possessing food requiring such treatment. The North American Indians, who had maize, pounded it in this manner to make a coarse meal or hominy; large stones in their villages formed permanent mortars. Their pestles were sometimes fortuitous bowlders of convenient shape, sometimes they were fashioned into a shape like a painter's muller, or even approximating the form of dumb-bells. Collections of curiosities abound with specimens of this rudimentary grinding-mill. The Smithsonian Institution has many such from North America and the South Seas.

The *mortarium*, or *mola trusatilis*, was a modification of this form, and Pliny states the bread made of the broken grain to be superior, in the estimation of some, to that more closely ground in the mills of more perfect construction, and leaves us to infer that throughout the greater part of Italy the grain for bread is pounded in a mortar by an iron-shod pestle. The Romans had great variety of bread, the best and most fashionable the *alica;* also *ostrearius* (oyster-bread), *artolagonus* (cake-bread), and many others. (See BREAD.) A passage in Pliny suggests that in course of time the mortar was ridged and the pestle notched, forming a machine which had a grating action upon the grain. See MORTAR.

When the upper stone or *runner* was enlarged and furnished with a handle, by which it was rotated upon the nether or bed-stone, the device may be said to have crossed the line between the *mortar* and the *mill*. The grain was fed in at an eye in the axis of the runner, and the meal escaped at the space between the stones at the outer margin of their effective faces, as shown at Fig. 2315. Such a mill was the *quern*, common in Italy and Britain in Roman times and since.

The ancient Egyptian mills, says Wilkinson, were of simple and rude construction. They consisted of two circular, horizontal stones, nearly flat; the lower one fixed, while the upper one, called the *rekkab*, or rider, in Arabic and Hebrew, turned on a pivot or shaft rising from the center of the lower one. It was turned by two women, seated, each holding the perpendicular handle, and operating by a concerted push and pull motion. The modern Egyptian hand-mill is substantially similar. Their larger mills were turned by oxen or asses, like those of the Romans. The millstones were of hard grit or granite, and are occasionally met with in the ruins.

The grinding of grain for a family was performed by women or slaves, and, the grist being usually sufficient for a single meal only, the work was a daily

Fig. 2315.

Oriental Mill.

occurring one. Samson ground in the prison-house. Job spoke of his wife grinding for a stranger. The Master spoke of the days of tribulation surprising two women grinding at the mill. Moses forbade the taking of the millstone to pledge, as it was a man's life, — a daily necessity, a grist for a meal being ground at a time. The last of the Egyptian plagues was the death of the first-born, from that "of Pharoah that sitteth upon his throne, even unto the first-born of the maid-servant that is behind the mill." The citation seems to include the extremes of the social scale.

When the labor of cattle was substituted for that of mankind, the upper millstone was called *meta* and the lower *catillus*, such mills being known as

Digitized by Google

molæ jumentariæ. The sweep to which the cattle were yoked was fastened to the runner which rotated upon the bed-stone. Since a time that the memory of man runneth not to the contrary, the Phœnicians have had mills for bruising olives, constructed on the plan of the Chilian mill, one stone rolling on its edge in a circular track around a post planted vertically in the center of the track. (See OIL-MILL.) Such was probably a common form of the Syrian cattle-driven grain-mill.

The cattle-driven grain-mills in Rome, about the time of Constantine, numbered three hundred.

Strabo informs us that mills were driven by water in the period of Mithridates of Pontus, the contemporary of Cæsar and Cicero. Such mills were driven by the current of the Tiber a little before the time of Augustus. It is not certain that these were grain-mills.

Windmills were introduced from Greece by one Paulo, and were used for grinding grain, if we may credit Pomponius Sabinus.

Antipater, time of Cicero, refers distinctly to the use of water-mills in an epigram: —

"Cease now your work, ye maids, ye who labored in the mill; sleep now, and let the birds sing to the ruddy morning, for Ceres has commanded the water-nymphs to perform your task; these, obedient to her call, throw themselves on the wheel, force round the axle-tree, and by these means the heavy mill."

Palladius advises the erection of water-mills on estates where streams afford the opportunity of saving manual labor in grinding grain.

Public mills were established in Rome A. D. 398, and were driven by the surplus of water brought to Rome by her splendid aqueducts. They were principally at the foot of Mount Janiculum.

In the sixth century (A. D. 536), when Vitiges, king of the Goths, harassed Rome, and stopped the water of the fourteen aqueducts which entered the city, the mills were stopped thereby, and great distress was the consequence. The grand old soldier Belisarius moored boats in the current, and provided them with paddle-wheels, by which the mills were driven and the people supplied with meal. The Goths tried to destroy them by throwing logs into the stream, but the Romans intercepted these by booms.

Water-mills soon became common in Gaul and Germany, and we read of some on a tributary of the Moselle A. D. 379, and a mention of them by Fortunatus in the next century.

It is needless to particularize farther, as the notices of water-mills in France, Bulgaria, Italy, and elsewhere, are numerous in the writers from the fifth century down.

The moving stone, known as the *runner*, is usually the upper stone, as shown at Fig. *G* in the plate on the page opposite. Variations from this practice are shown at *K*, where the *runners* are beneath, and at *F*, where both stones are driven, but in contrary directions.

The following terms apply to grinding-mills and to parts many of which are represented in figures *G H* of the plate. *L* is an enlarged view of the parts around the spindle and eye.

Bed-stone (*a*); a stationary millstone, usually the lower one.

Runner (*b*); a revolving millstone, usually the upper one.

Run of stones; a pair of millstones in working order.

Spindle (*d*); a shaft which supports and drives the runner.

Step or *ink* (*e*); the socket which holds the *toe* of a vertical shaft or spindle.

Bridge-tree (*f*); the beam which supports the *ink*.

Bush (*g*); wooden chocks called *followers* surrounding the spindle within the eye of the bed-stone. The upper bearing of a millstone-spindle.

Keys (*h*); wedges by means of which the bush is fastened in the bed-stone.

Driver (*i*): a cross-bar by which the motion of the spindle is conveyed to the runner.

Coffins; sockets in the eye of the runner for the ends of the driver.

Balance-rynd (*j*); an iron bar stretching across the eye of the runner, and by which it is poised on the spindle.

Cock-eye (*k*); a cavity on the under side of the balance-rynd to receive the point of the spindle.

Cock-head; the upper point of a millstone-spindle.

Horns; the points of the driver.

Eye (*n*); the central aperture of a millstone.

Hoop (*o*); the enclosing case of a run of stones.

Hopper (*p*); a conveying trough or funnel for feeding a mill.

Shoe (*q*); a conducting spout or trough from the hopper to the eye of the stone.

Spout (*r*); the issuing nozzle for the ground meal. A projecting ventage.

Damsel (*s*); a projection on a millstone-spindle for shaking the shoe.

Dress; a system of land and furrows. A mode of preparing the grinding-surface.

Face; the grinding-surface of a millstone.

Rynd; the bar by which the runner is poised on the cock-head.

Skirt; the outer margin or edge of a millstone.

Furrows; grooves in the face of a millstone to expedite the grinding action.

Land (*x*); level surface between millstone furrows.

Leader (*t*); a furrow extending from the eye to the skirt of a millstone.

Second furrow (*u*); the branch-furrow nearest the eye of a millstone.

Skirt-furrow (*v*); the branch-furrow nearest the skirt of a millstone.

Gouge-furrow; one concave at bottom.

Track-edge; the abrupt edge of a millstone furrow.

Feather-edge (*w*); the shallow edge of a millstone furrow.

Quarter (*y*); a section of millstone dress consisting of a leader and its branches.

Bosom (*z*); a sunk area in the face of a millstone around the eye.

Tram-staff; an instrument to test the squareness of the spindle with the face of the bed-stone.

Red-staff; a straight-edge employed to detect irregularities in the face of a millstone.

Proof-staff; a metallic straight-edge by which the red-staff is corrected.

Wing (1); a strip (commonly of leather) attached to the skirt of the runner to sweep the ground meal into the spout.

Lighter-screw (2); a screw for adjusting the relative distance of the grinding-surfaces.

Husk (3); the supporting frame of a run of millstones.

Grit; a kind of sandstone.

Grits; hulled and coarsely ground grain.

Food; the substance being ground.

Cutlins; half-ground fragments of grain.

Dressing; preparing the face of a millstone for grinding.

Face-cracking; roughening the land-face of a stone by means of numerous blows with a pick-hammer.

Digitized by Google

Tramming; adjusting the spindle so as to be exactly at right angles with the bed-stone face.

Raking; an action in which, the runner being out of balance, one edge rakes or presses unduly.

Chuckle; the runner is said to chuckle when it rocks upon its center while rotating.

Facing; preparing the working-surface or *face* of a millstone.

Wreathe; the food is said to wreathe when its particles hug the eye so closely as to retard or prevent their descent.

Sling; to swing from side to side (applied to a millstone).

In tram; the spindle being perpendicular with the face of the bed-stone.

Out of tram; the spindle being oblique with the face of the bed-stone.

Gummed; having an indurated coating of vegetable matter.

Killed; meal over-heated in the act of grinding.

Round; not unduly pulverized; meal rather granulated than powdered.

Bush loose; loose in its upper bearings (applied to the spindle).

Draft; the degree of deflection of millstone furrows from a radial direction; thus, in a *seven-inch draft*, the track-edges are tangential to a seven-inch circle.

Fourteen quarter dress; a system of fourteen sets of furrows.

Grit; degree of hardness or texture, — as hard grit, soft grit, coarse grit.

The term *hopper*, although now usually applied to a stationary conductor or funnel, was formerly applied to a shaking one, and hence the name.

The *killing* of the meal usually takes place between grinding surfaces, which, having been worn smooth and somewhat glazed, are set too closely together, and the flour, sliding between instead of rolling over the surfaces, becomes parched, so as to impair its vitality and capacity for panary fermentation. A perfect dress will *slide* the bran and *roll* the flour.

A of the plate is a form of portable mill, adapted to be worked by manual labor, or, by substitution of a band wheel for the crank, by horse-power. The shaft has a bevel-wheel gearing into a pinion on the spindle of the runner.

B is an English form of hand-mill made for the colonies and foreign market. It has a fly-wheel, bevel-wheel, and pinion, which drive the upper stone. Both stones are of buhr. The grain is fed from the hopper in the usual manner, and conducted by the shoe to the eye of the runner, a damsel on the millstone-spindle shaking the shoe.

In some mills and in many forms of corn-crackers metallic plates have been substituted for stones. Among the first of these was the French military mill, the invention of Francis Devreux, to whom a patent was granted for it in 1824. The principle is that of metallic groove plates turning in a vertical plane; the grooves cut radiating from the center of the plate. One of the plates is fixed to the end of the frame of the mill; the other revolves upon an axis fixed in the center of the fixed plate at one end, and in the side of the frame in the other. The grain is fed through an aperture in the fixed plate. See millstone-plate.

E is an emigrant mill, attached to the tongue of a wagon, and designed to be worked by two cranks.

The Shakers of New York reduce their roots to powder by means of a crushing-mill *C*, succeeded by a powdering-mill *D*. The first is on the principle of the Chilian mill, and reduces the dried roots to the size of samp or fine hominy. The stones are of Esopus granite, 4 feet diameter, 1 foot thick, and weight 2,000 pounds each. They turn on their axle, which is at right angles to the vertical axis by whose rotation they are caused to revolve around a common center, and also rotate on their own axes. The principle of the Chilian mill is well understood, and its effect is very powerful. As the outer periphery or face of the stone describes a larger circle than the inner, the face of the stone has a constant rubbing action on the bed-plate, and the material subjected to the action of the stones is much more forcibly grated than it would be by the mere crushing weight of a traversing stone.

The roots, cracked and reduced to a certain fineness in the crushing-mill, are next placed in the powdering-mill *D*, which has a rounded bed-stone of granite and two runners in the shape of truncated cones, which have a rotation on their own axes, and also a revolution around the vertical axle by which the power is transmitted. This mill is very effective. In this form of grinding-mill is illustrated the crushing action just referred to. The outer portion of the face of the upper stones — or that portion of each which for the time being is nearest to the rim of the bed-stone — is subjected to the greatest amount of attrition, being farthest from the common, vertical axis of revolution; it thus causes the other portion of the face, or that nearest the center of the bed-stone, to advance in the general direction of motion, the outer portion being detained by the greater friction, and the result being a rotation resulting from the revolution. Rotary harrows are constructed on the same principle, a rotation being imparted to the individual harrows by power exerted in the direct line of draft.

In one form of the English farm-mill *F* the upper and lower plates rotate in the same direction and at nearly equal velocities, but not on the same center. Their eccentric setting gives their grooved surfaces a shearing cut upon each other.

Carr's disintegrating flour-mill (English) is shown by a general view at *I* and by a partial sectional view at *J*.

a and *b* are circular metallic disks, which rotate in contrary directions upon the shafts *c* and *d*, which are situated in the same line. On the inner surfaces of these disks are concentric rings of projections, called *beaters*, the rings on one disk intervening alternately with those on the opposite disk, and moving in a contrary direction. Several concentric rings of beaters may be thus made to operate conjointly.

The revolving beaters are inclosed in a casing *e*. The grain is delivered down the fixed shoot *f* through the orifice in the outer casing, into the innermost cage, from which it is instantly projected by centrifugal action through the machine and delivered, in a shower radiating from every portion of the circumference, into the outer casing, in the form of a meal similar to that thrown out by the ordinary millstones; to this state the grain is reduced by being dashed to the right and left alternately by the bars of each of the successive cages revolving in opposite directions at a very high rate of speed. As it falls to the bottom of the casing, the meal is continually removed by the screw *g*; it is then passed through the usual bolting-machines to separate the bran, and subsequently through silk dressing-machines to separate the fine flour.

The machine is driven at a speed of about 400 revolutions per minute; and the outermost ring being 6 feet 10 inches diameter, the last beaters have a velocity of 140 feet per second, or about 100 miles per hour.

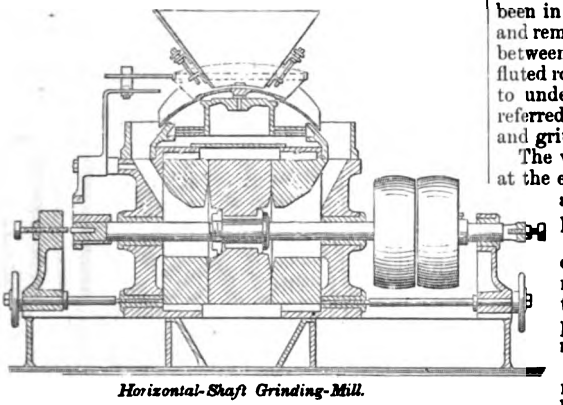
K represents Westrup's conical buhr-stone flour-mill. In, this the upper stone is fixed while the lower revolves, and weighs but about 1½ cwt. instead of 14 cwt., as the ordinary stones do. *a* is the upper, *b* the lower fixed stone; *c* the upper and *d* the lower runner, both fixed on the same spindle.

Fig. 2316.

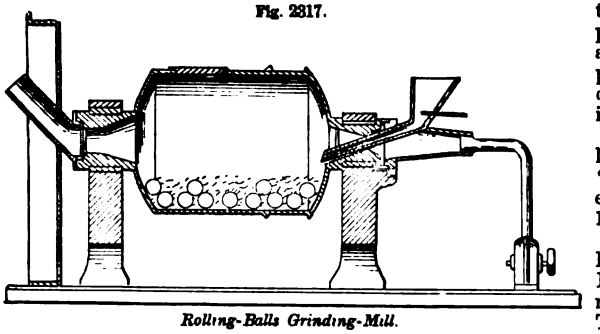


Horizontal-Shaft Grinding-Mill.

This arrangement diminishes the power required, and is said to deliver a much larger quantity of flour in the same time.

Fig. 2316 is a form of mill in which the runner rotates with a horizontal shaft passing through boxes in the adjustable standards, by whose movement the other stones are adjusted. The grain

Fig. 2317.

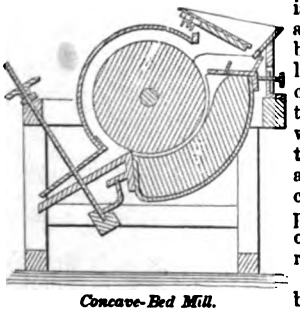


Rolling-Balls Grinding-Mill.

passes from the hopper through two spouts, and passes through ways in the standards and the side stones.

In Fig. 2317 the material is fed into the cylinder through one of the tubular journals, and is subjected to the action of metallic balls running loosely in the rotating cylinder. A blast enters through the inwardly flaring aperture of the journal at the feed end and carries the powdered particles through the other journal to the receiving chamber.

Fig. 2318.



Concave-Bed Mill.

In Fig. 2318 the bed-stone is a concave, which may yield to any hard substance and preserve it from injury.

Many of the new processes for putting wheat into a convenient shape for cooking are but revivals of old modes. We have spoken in this article, and under BREAD, of the Roman preference for decorticated grain, rasped in a mortar and then simply broken. The Hungarian plan, which may have been in use for centuries, is to decorticate the grain and remove the bran, and then rasp the hulled kernels between a complicated series of differently speeded fluted rolls. Other devices for this purpose are referred to under DECORTICATOR; and allied machines are referred to under HULLER. Pearl barley, hominy, and grits are hulled grains.

The ventilating of millstones, by a blast of air in at the eye and out at the skirt, is old as Gendebein and Houyet's patent, January 5, 1847. They proposed to use plenum or vacuum.

Oliver Evans's *hopper-boy* patent, a means of feeding grain to the millstone, was pronounced by Thomas Jefferson so important that the inventor ought not to be allowed a patent on it, it being an absolute necessity to a miller when once discovered.

The regrinding of roughly ground or coarse meal was practiced by the Romans, and has been revived in latter times by the Germans and French; by the latter under the name *mouture économique*. The grain is coarsely ground, bolted; the coarse portions and bran reground again and again. The various grades and kinds of flour or meal thus obtained were called by Pliny *similago, simila, flos, pollen, cibarium*.

Two other plans may be noticed; one which produces what is called *entire wheat flour*, the bran being ground to an impalpable powder and mixed with the flour. Also a French plan, in which grinding is dispensed with; the wheat being decorticated, macerated, and crushed by rollers into a dough fit for baking.

The first steam flouring-mill in England, perhaps in the world, was the "Albion," erected at the Southwark end of Blackfriars' Bridge, London, in 1783.

The best-appointed *grinding-mill* in England is said to be the City Flour-Mill of London. Its capacity and arrangement are thus described by Mr. Tomlinson: —

"The mill, which is fire-proof, is 260 feet in length and 60 in width. There are thirty-two pairs of stones all furnished with the blowing-apparatus, the runner of each pair being worked by a strap. A long horizontal trunk placed above the millstones is supplied with condensed air by means of a powerful fan. From this trunk proceeds a smaller trunk obliquely into the casing of each pair of millstones, and when the blast has served its purpose it escapes up another oblique trunk, into a second long horizontal shaft, in which the air is rarefied by means of a fan. This fan conveys the air into a chamber lined with woolen cloth which arrests the flour carried off by the blast.

"The wheat is hoisted to the top floor, where, after undergoing certain cleansing operations, it is let down to the stones. The meal is conveyed along horizontal trunks, by means of archimedean screws working in them, to a series of bucket-elevators attached to an endless band working in a vertical plane over and under rollers at the top and bottom. These elevators distribute the meal among sixteen

Digitized by Google

silk dressing-machines, each of which is 36 feet long, 3½ feet in diameter, and inclosed within a wooden casing. The silk-machine consists of an octagonal wooden framework attached by radial bars to a central axis. The frame is covered with a fine silk cloth, hard in texture and tightly stretched. The axis is inclined ⅜ inch to each foot of its length; the two ends are open, and the meal, being poured in at the upper end, is sifted through the bolting-cloth which covers the eight sides, as the frame revolves.

"As a means of jarring the frame to prevent the clogging of the meshes of the bolting-cloth, the radial rods of the frame have wooden balls threaded loosely upon them, so that as the frame revolves they fall from the axis upon the circumferential bars, and then back again upon the axis as the position of the radial bars changes. The fine flour which passes through the cloth is conducted to a bin; the pollard and bran are conducted to a dressing-machine.

"The average quantity of wheat ground per week is 20,000 bushels. Wheat can be ground and dressed in fifteen minutes, during which time it passes three times from the top to the bottom of the mill by means of screws and elevators. But few hands are employed, the work of the mill being mostly performed by steam-driven machinery. The steam-engine in this establishment is on the marine principle, and was formerly one of the stationary engines of the Blackwall Railway, when the carriages on that line were moved by means of a rope.

"The nominal power of the engine is 220-horse-power. There are seven boilers for generating steam, and they are made to consume the smoke by causing one fire as soon as it is supplied with coals to discharge its smoke into the adjoining furnace."

2. A lapidary's wheel of lead, the disk surface of which is touched with emery and water. It follows the *slitting* or *roughing* mill, and like them is mounted to rotate on a vertical axis. See LAPIDARY'S MILL.

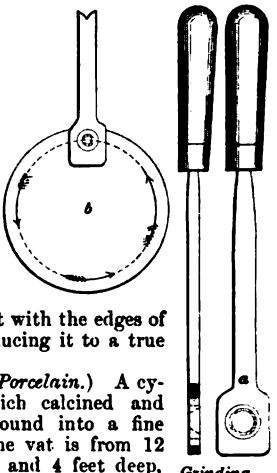
Grind'ing-slip. A thin slab of oil-stone or hone to reach edges of tools which cannot be conveniently applied to the usual stone.

Grind'ing-spheres. Fig. 2319 illustrates Guy's device for grinding balls to a true surface. The ball, previously turned as nearly spherical as may be, is placed in the conical aperture of the holder *a*, and two rings *b* set from each other a distance equal to the diameter of the ball and pressing tightly against it, are made to rotate at right angles to each other, carrying the ball with them and bringing its protuberant portions in contact with the edges of the aperture, thus reducing it to a true spherical surface.

Fig. 2319.



Grinding-Spheres.

Grind'ing-vat. (*Porcelain.*) A cylindrical tank in which calcined and stamped flints are ground into a fine paste with water. The vat is from 12 to 14 feet in diameter, and 4 feet deep, paved with chert-stone. It acts on the principle of the ARRASTRA (which see), large blocks of chert being attached by chains to revolving arms and dragged upon the pavement of the vat. Chert-stone is used because of its chemical affinity to the liquid, in order that no deleterious ingredients may be introduced by the mutual attrition of the *muller* and pavement in this operation, which is equivalent to porphyrization.

Grind'ing-wheel. Fig. 2320 is a small grinding and polishing machine, adapted for receiving various interchangeable spindles carrying grindstones, emery-wheels, or a circular brush. It is operated by a treadle, has a stand for a water-can, and slots at the sides in which the spare wheels with their spindles may be placed.

The lower machine in the same figure is adapted for grinding large flat surfaces. It consists of an inner and an outer circle *a b*, between the radial divisions of which segmental pieces of grindstone are inserted and fixed by set screws *c c*. The work is placed on the carrier *d*, which traverses on the table *e*.

a b c (Fig. 2321) represent guides for giving a uniform bevel to the cutting-edges of tools. In *a* this is effected by blocks of wood having the proper slope, to which the tool is fastened and the block clamped to the table. *b* is provided with a quadrant which allows of a vertical adjustment. The grinding-wheels *d e* are horizontal. *c* is adapted for affixing to a block, which is applied alongside of a vertical wheel. The tool is clamped to a holder, which has horizontal and vertical graduated arcs, admitting of adjustment to any required angle, so as to form a double bevel.

Grind'stone. Grindstones are made from the more compact sandstones, varying in texture and compactness according to the work required. Those

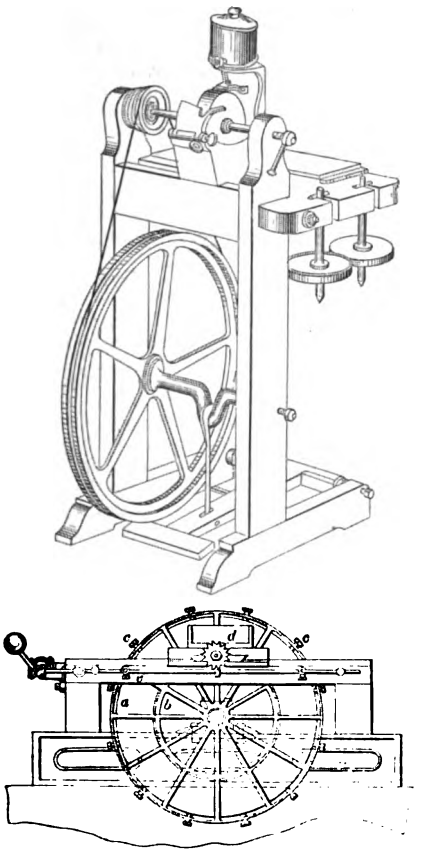
Fig. 2220.



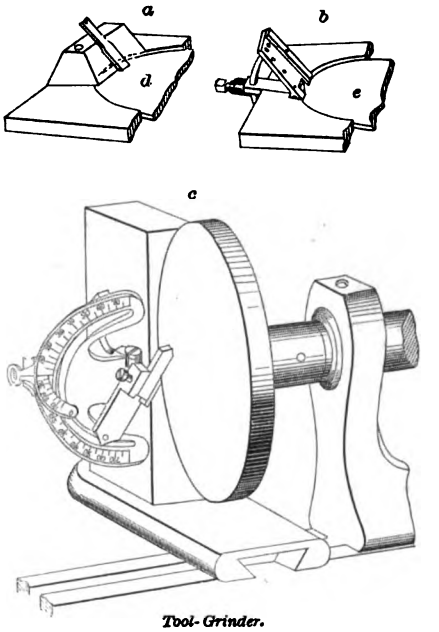
Grinding-Wheels.

of England are highly esteemed. Different localities of that country afford such as are required for almost every purpose. Among these the "Newcastle" stones, from the coal measures of Northumberland and the adjacent counties, have a pre-eminence in England for general purposes; others are used for grinding, while many varieties are employed as plane surfaces for whetstones. Other qualities are used for hones. A German variety is famous for this purpose. The very finest qualities, composed of an almost impalpable agglutinated powder, are used as oil-stones. Such are the "Water of Ayr," and "Blue" stones, and the "Turkey" oil-stone. The old "Royal Exchange" of London was paved with this stone, and when it was burned, about 1834, the pavement yielded a handsome amount towards the re-erection.

The Nova Scotia and Berea, Ohio, grindstones are largely employed in this country; these may be obtained of very large size and uniform quality. The Washita, Arkansas, stone is of the very finest quality, being sharp and clean, and is made into a great variety of forms; grindstones, whetstones, hones, and slips of various sizes and forms.

In dressing rough grindstones, the process of hacking is employed. *Hacking* consists in notching the projecting parts with a short-handled hammer resembling an adze. *Laps* used in polishing stones, etc., are *jarred* by holding an old knife against their edges, so as to vibrate or *chatter*, making a slight in-

Fig. 2221



Tool-Grinder.

dentation at each jump; these serve to retain the finely powdered emery or rottenstone mixed with adhesive material with which the lap is covered.

For clearing the surfaces of stones, in which particles of iron or steel have become imbedded, a square bar of ½ to ¾ inch iron is held and wabbled against the edge while in motion. This is called *straggling* or *raging*.

Turning or *roving* is effected by reversing the motion of the stone and holding a hooked flat tool against its edge, which is afterwards farther smoothed by the roving plate.

The series of operations in making grindstones is about as follows.

The layer or ledge of rock being uncovered, channels are cut at each end of the slab to be removed, and then a row of holes is drilled on the line where the fracture is to be made. Steel wedges are driven into these holes, driving them consecutively a little at a time, keeping all on a strain, until the mass cleaves from the ledge forming a large parallelopiped. This block is similarly divided into squares, and these, if too thick, are split or cleft in the plane of the stratum to thickness required.

The square stone is now chipped into an octagonal shape, when it is ready to have the eye made. This is done by a pick-hammer.

It is then mounted on a mandrel driven at the rate of 125 rotations a minute. The turning-tools are five feet long, one and a half inches wide, and five eighths of an inch thick, tapered to a point by the blacksmith and afterward hammered to a hooked point by the workmen, who turn from 100 to 200 per day, according to size. An exhaust-fan withdraws the stone-dust, and a conductor leads it to the outside of the building.

The stones are placed in a row, an iron rod and wooden axis through them, a wooden head at each end being jammed against the stones by nuts. Slats nailed to the wooden heads and hoops over the slats complete the package. The works at Berea, Ohio, are the largest in the United States.

Digitized by Google

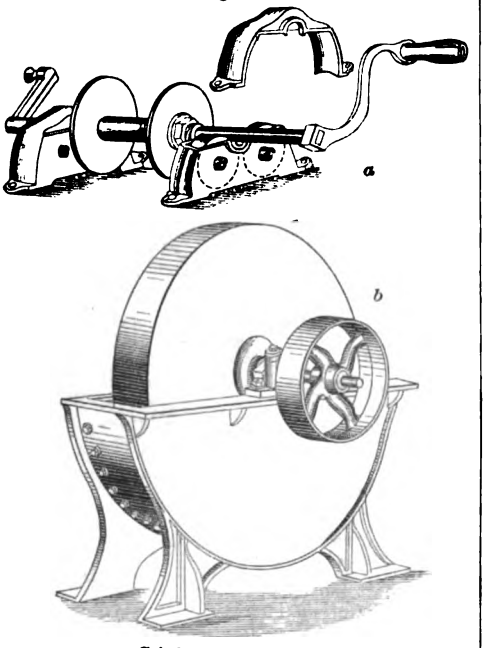
The large grindstones employed in grinding gun-barrels are 8 feet in diameter, and are used until they are reduced to a diameter of about 2 feet, when they are rejected. They are placed in a case with holes for the introduction of the barrel, which is temporarily slipped upon a rod, a crank at one end of the latter enabling the barrel to be turned while the stone is rapidly revolved. The case keeps the water from splashing upon the workman, and may afford some protection against pieces when the stone bursts, as it sometimes will, owing to the rapid rate at which it is driven. The danger of fracture cannot be entirely obviated, but may be much lessened by clamping the stone on its axis by disks instead of wedges inserted between the sides of the eye and the square arbor on which it it suspended. It would seem possible to avoid the eye altogether, and depend upon check-pieces with studs or projections which penetrate into depressions in the sides of the stone. The stones are so very heavy that their fracture when in rapid motion is apt to do great damage to life, limb, and property.

Artificial stones are largely employed, especially in dry-grinding and polishing.

The *corundum stone* used by the Hindoos and Chinese is composed of corundum powdered, 2 parts; lac-resin, 1 part. The two are intimately mixed in an earthen vessel, kneaded, flattened, shaped, and polished. A hole for the axis is made by a heated copper rod.

The grain is more or less fine, according to the grade of the powdered corundum. The wheel is

Fig. 2322.



Grindstone and Hangings.

mounted horizontally, and revolved by a bow in the right hand of the workman, while the left applies the work to the stone.

The following recipe may also be employed:—

Sand of the required fineness, 3 or 4 parts; shellac, 1 part; melted, incorporated, and molded under pressure.

Ransome's artificial stone, sand agglomerated by silicate of lime, has been used for grindstones with excellent effect.

In a test trial between Ransome's (English) artificial grindstones and some Newcastle grit to ascertain which had the greatest abrasive effect, it was found that the Ransome stone ground away ¼ ounce from a steel bar ¾ inch diameter in sixteen minutes, while a Newcastle stone (natural grit) driven at twenty per cent greater speed required eleven hours to effect the same work. (London "Engineer.")

a, Fig. 2322, illustrates an arrangement for hanging grindstones in which the stone is held between adjustable disks and journaled between anti-friction rollers.

b, Fig. 2322, is an improved form of grindstone stand, having a pulley for turning, a lubricating oil-cup, and side-disks for holding the stone.

Stones for grinding cutlery vary in diameter from 4 inches to 2 feet. The faces of some, as of those for grinding razors, are convex. Those for dry grinding, an operation very injurious to health, have a flue above through which the small particles of stone and metal are driven by an air-blast.

Magnets have also been placed near that portion of the periphery of the wheel where the work is applied, in order to attract the filings, which would otherwise be inhaled by the workmen.

The angles formed by the faces of cutting-tools increase in proportion to the hardness of the material to be operated upon. Thus, the razor has an angle of from 17° to 20°, wood-cutting tools 25° to 45°, and tools for iron and steel 60° to 70°. For reaming-tools the angles are greater; for the hexagonal broach, 120°; octagonal, 135°.

Great care should be taken, where tools requiring an accurate edge are to be ground, to keep the face of the stone true. This may be effected by hanging a pair of grindstones so that their faces shall touch. Their rotation thus causes each to wear away the inequalities of the other.

The teeth of circular saws may be sharpened by a small grindstone having on the edge a ridge suited to the form of the teeth, and a slide fitted with an adjustable stop to regulate the abrasion.

Gripe. 1. (*Nautical.*) *a.* The *fore-foot* of a ship, on to which the *stem* is planted. The forward end of the *keel*. It is scarfed to the stem-piece and false-keel, and is secured by a horseshoe or ring to the stem. See STEM.

b. A broad plait of rope or bars of iron with lanyard rings and claws, passing over a large boat and by which it is secured to the ring-bolts of the deck.

c. One of a pair of bands passing round a boat near the stem and stern when suspended from the davits to prevent the boat from swinging about.

2. A brake applied to the wheel of a crane or derrick. It generally consists of an iron hoop under the control of a lever, and is drawn closely around the wheel to check its motion.

3. (*Weapons.*) Of a sword-hilt. The part which is grasped by the hand.

Grip'pers. (*Printing.*) The fingers on an impression cylinder which seize the paper by one edge and carry it to, and sometimes through, the press. In some cases tapes conduct it after it has been fed in by the grippers.

Grist. 1. (*Rope-making.*) A given size of rope *Common* grist is a rope 3 inches in circumference, with twenty yarns in each of the three strands.

2. (*Milling.*) A batch of grain to be ground in a custom mill, or the result of the grinding less the toll.

Grist-mill. A grain-grinding mill. See GRINDING-MILL.

Digitized by Google

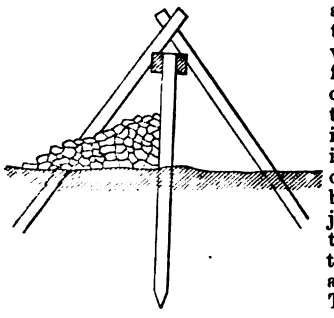
Grit. A sandstone used for grinding. The term *millstone-grit* shows that it was the material used in grinding-mills, but its use now is principally for *grindstones* and *whetstones*, *buhr* being used for *millstones*. *Buhr* is a foraminous quartz.

Gro'gram. (*Fabric.*) A coarse stuff of silk, or silk and mohair. The name is French (*gros-grain*, coarse texture).

Admiral Vernon, 1750, introduced rum and water as a ration on board ship, and wore a *grogram* coat. The soubriquet *Old Grog* referred to the coat, but was afterwards applied to the beverage.

Groin; Groyne. 1. A timber structure on a beach to accumulate shingle and sand, so as to form an advance protection from the energy of the waves to the land situate in its rear. It is formed of piles driven into the beach and projecting above it, to which are fastened land ties and planking. The illustration shows an open framing of timber placed parallel to the shore on the line of low water, and common in Holland. To avoid the washing out of the sand by the reflux of the wave, an apron of stone is placed at the foot.

Fig. 2323.



Groin.

On the Sussex coast, south of England, the groins are from 150 to 250 feet long. The piles 4 feet apart, 12 to 25 feet in length. Planking 2½ inches thick; land ties 25 feet in length. Every 16 feet in length contains 4 piles, 1 land tie, tail piles and keys, tie bar, blocks, and bolts, 180 superficial feet of planking, 140 6-inch spikes, and costs $150. See SEA-WALL; BREAKWATER.

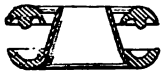
2. (*Architecture.*) The line of junction of two intersecting arches. A *Welsh* groin is one crossing transversely, but having a lesser pitch or hight.

Groined Arch. (*Architecture.*) An arch intersected by another cutting across it transversely. The line of junction is the *groin*.

Groin-rib. (*Architecture.*) A rib or projecting member following the line of junction of the two arches forming a groin.

Grom'met. 1. (*Nautical.*) A ring formed of a strand of rope laid round and spliced. Used as a *hank*, a *thimble*, or with large oars, in connection with a pin, as a substitute for a row-lock. Metallic grommets, forming eyelets, are sometimes substituted. In the example, an iron flange is cast to the wrought-metal thimble; after insertion the edge is spun over upon the other cast-metal ring.

Fig. 2324.



Grommet.

2. (*Ordnance.*) A wad made of rope, rammed down between the ball and the charge. Made of oakum and bound with spun-yarn, it is called a *junk-wad*.

Groove. 1. (*Joinery.*) A channel in the edge of a board. In *matched* boards it receives the *tongue*.

2. (*Guns.*) A spiral channel between the lands in rifling.

Grooved Bit. A wood-boring tool adapted to be used in a brace, and having a cylindrical stem with a spiral groove. See BIT.

Grooved Wheel. 1. One having circumferential indentations, as a mode of increasing the traction or effective frictional surface contact. The edges of corresponding wheels have counterpart channels and ridges, so as to increase the area of the contacting surface and allow them when driven against each other to attain a mutual *bind* or *grip*. A *friction-wheel*. The two constitute a *friction-gearing*.

Fig. 2325.

Grooved Wheels.

2. A band-wheel or pulley having peripheral depressions for a round band, as in some lathes.

Groove-ram. (*Needle-making.*) A stamp for making the groove in which the eyes of needles are formed.

Groov'ing-planes. Carpenters' and joiners' planes which are adapted for cutting grooves, such as the *plow*, *fillister*, *router-plane*, *banding-plane*, etc. (which see). Planes are made in sizes to suit, in pairs known as *hollows* and *rounds*.

Gros. (*Fabric.*) A heavy silk with a dull finish.

Gros-de-Na'ples. (*Fabric.*) A plain, heavy, woven fabric, made of organzine silk.

Ground. 1. (*Navigation.*) To touch bottom.

2. (*Fabric.*) The prevailing color.

3. Sediment.

4. (*Plastering.*) Flush strips in plastering for the attachment of moldings and other finishing.

5. The surface of the ground, level or otherwise, or a representation thereof; as, —

Ground plan. Ground plane.

6. The parts of a foundation or of a structure near the base; as, —

Ground-joist. Ground-sill.
Ground-plate. Ground-work.
Ground-plot.

7. (*Painting.*) The color first laid on.

8. (*Japanning.*) The pigment mixed with hard varnish which forms the basis for the japan or polished varnish surface.

9. (*Engraving.*) An acid-resisting composition of, asphaltum, 4; Burgundy pitch, 2; white wax, 1. This is melted and mixed, and then tied up in a silk rag.

In using, the plate is heated over an alcohol lamp or brazier, and the composition smeared on. It is then spread by a silk dabber, and blacked by the smoke of a candle or an oil-lamp. When cool it is ready for the *etching-point*. See ETCHING.

Where the point removes the ground, the plate is exposed to the subsequent action of the acid, and a line or a dot, as the case may be, is made in the plate.

Soft-ground is made by adding 1 part of lard to 3 parts of common etching ground. It is used for a certain kind of etching called *etching on soft ground*. See ETCHING.

In mezzotint engraving, the *ground* is said to be *laid* when the whole face of the plate to be occupied by engraving is raised by the *cradle* so as to have a *burr* which would print a uniform black. This is scraped away for the lights. See MEZZOTINT ENGRAVING.

10. (*Telegraphy.*) *a*. Accidental connection between the line wire and the earth.

b. The earth in its capacity as the return-circuit carrying body. The wire is carried to earth and connected to a *ground-plate*, or in cities to a water or gas main, which forms an admirable and extensive conductor.

Digitized by Google

Ground-au'ger. An earth-boring auger. See AUGER. Figs. 441–443.

Ground-glass. Glass whose surface is *ground*, so as to break up the pencils of light passing through it, preventing the passage of a distinct image. Lamp globes are ground in order to mellow and disperse the light passing through them. The process is done mechanically or chemically; the wheel, sand-blast, by rotating with pebbles inside, or by fluoric acid.

Ground'ing-in. The application of the secondary and subsequent colors to a cotton cloth, after it has received the color of the first block. It is a term used in the hand-block printing, and the *grounding-in* or *re-entering* may be of a *mordant*, a *topical-color*, or a *resist*. The correspondence of position of the color in the pattern is secured by points on the block; equivalent to the *register-point* of the chromatic process of type-printing or lithography.

Ground'ing-tool. (*Engraving.*) The rocker by which the mezzotint steel plate is roughened.

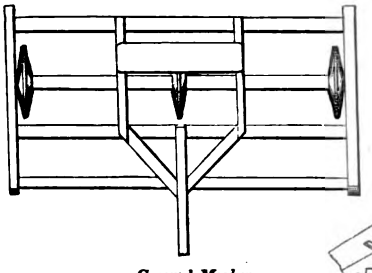
Ground-joint. A joint made by grinding together two pieces of metal with emery and oil; or pieces of glass with fine sand and water: the glass stopper is a specimen of the latter.

Ground-joist. (*Carpentry.*) A joist of the basement or ground floor. Often termed a *sleeper*.

Ground-lay'ing. (*Porcelain.*) A coating of boiled oil to the surface of porcelain, in course of manufacture, to receive the color. *Bossing.*

Ground-mark'er. An implement for laying off corn-rows. It is frequently attached to a corn-planter to make a mark for planting on the next bout. In the example, it is a frame with three sharp-rimmed wheels set at the desired distance apart, say 3 feet 8 inches to 4 feet, according to the size of corn and the practice of the country. The "King Philip" corn of New England may do with

Fig 2326



Ground-Marker.

36 inches, but the larger Southern varieties need 48 inches apart in the rows and between the rows.

Ground-mold. (*Civil Engineering.*) A templet or frame by which the surface of the ground is brought to the required form, as in terracing or embanking.

Ground-plan. A representation on a horizontal plane of the foundation, or of the arrangement of the lower tier of rooms of a building.

Ground-plate. 1. (*Building.*) The lower horizontal timber of a building on which the frame is erected. A *sill*.

2. (*Railway Engineering.*) A bed-plate for sleepers or ties in some kinds of ground.

3. (*Telegraphy.*) A metallic plate buried in the earth to conduct the electric current thereto. It should bear a certain proportion to the size of the conductor which is attached to it; it should have a surface as many times larger than the surface of the conductor as the difference in the conductivity of the conductor and the earth. Connection to the pipes of a gas or water main is usual in cities.

Ground-plot. A representation on a horizontal plane of the ground to be occupied by a structure or other engineering works.

Grounds. (*Carpentry.*) *a.* Pieces of wood nailed on as guides for the plastering which comes flush with the face of the *grounds*. To them the molding and other finishings are nailed.

b. Framing or pieces forming a basis for other structure, as *ground-sills*.

c. Sheathing upon *quarters* or *studding* to form a basis for cornice work or moldings.

Ground-seat. (*Saddlery.*) A ply of canvas or linsey drawn over the *straining* which supports the padding and seat of a saddle.

Ground-sill. (*Carpentry.*) A *sleeper*; or a lower timber, which supports the remainder of the frame.

Ground-table. (*Building.*) The foundation course of stones.

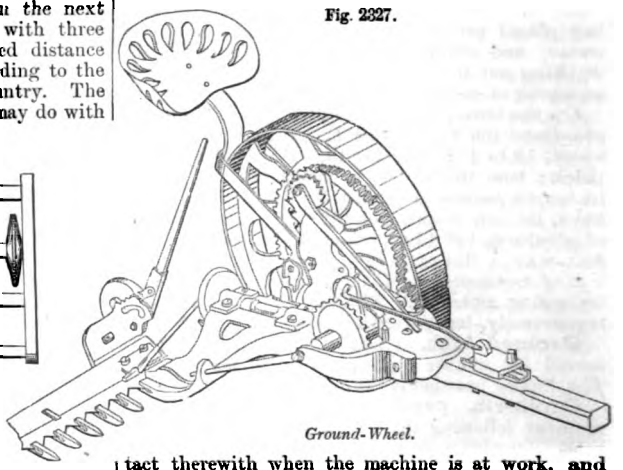
Ground-tack'le. (*Nautical.*) The ropes and tackle connected with the anchors and mooring apparatus.

Ground-tim'bers. (*Shipbuilding.*) Those which lie on the keel and are bolted to the keelson. *Floor-timbers.*

Ground-ways. (*Shipbuilding.*) The large blocks and planks which support the cradle on which a ship is launched.

Ground-wheel. That wheel of a harvester which, resting on the ground, is revolved by contact therewith when the machine is at work, and which drives the cutter.

Fig. 2327.



Ground-Wheel.

Similar wheels in other agricultural wheeled implements actuate subsidiary parts, such as the feed-wheels of drills, the thrashing cylinders and shoes of traveling harvesters, the rakes of hay-loaders, the reels of tedders and reapers, etc.

Ground-work. 1. (*Civil Engineering.*) *a.* The preparation of ground for the foundation of a structure, or giving it the required contour for any other purpose.

b. The basis or structural foundation of an erection.

2. (*Painting.*) The base color on which the painting is performed.

Grout. *a.* A thin coarse mortar used to run into crevices between the stones or bricks of a structure. "The Norman walls were of great thickness, and were filled up with small stones, amongst which mortar was poured in hot. This was called *grouting*; and in time the whole mass so hardened to-

Digitized by Google

gether as to acquire the consistence and strength of a solid rock." — WEALE.

b. A finishing or setting coat of fine stuff for ceilings.

Grove Bat'ter-y. A form of double-fluid galvanic battery, invented in 1839 by William Robert Grove, F. R. S. It has a glass jar or cell in which is placed a plate of zinc bent into cylindrical form, and thoroughly amalgamated. Within the zinc is a porous cup, in which is placed a strip of platinum.

In the outer cup is dilute sulphuric acid (1 of acid to 20 of water by measure), and in the inner or porous cup is strong nitric acid. See GALVANIC BATTERY.

Grow'ing-slide. A cell formed between two glasses, adapted as a *slide* for a microscope, and supplied with water by the capillary action of a few filaments of cotton extending thence to a little reservoir of water. It is designed for preserving algæ or infusoria in a growing condition.

Groyne. (*Hydraulic Engineering.*) A projecting defence extending out from the sea-shore or bank of a river, to prevent the land from being washed away. A shingle-trap. See GROIN.

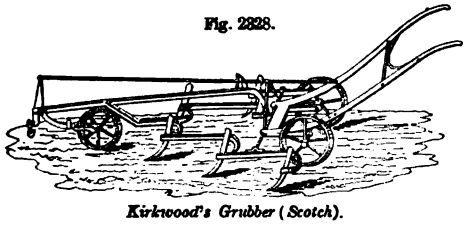
Groz'ing-i-ron. 1. An instrument with an angular steel projection, used for cutting glass before the general application of the diamond to that object.

2. (*Plumbing.*) A tool used in smoothing the solder joints of lead pipe.

Grub'ber. (*Agriculture.*) *a.* An agricultural implement used in Scotland for stirring and loosening the soil to plow depth. It is a heavy cultivator drawn by four horses, and supported on wheels. One form has an inner frame attached to the wheel-frame, and has two ranks of teeth, 5 in the front and 6 in the rear, cutting the balks between the preceding and outside of them. The teeth consist of colters armed with shares.

The form represented in Fig. 2328 is a heavy implement, not designed for tending crops, but to bring

Fig. 2328.



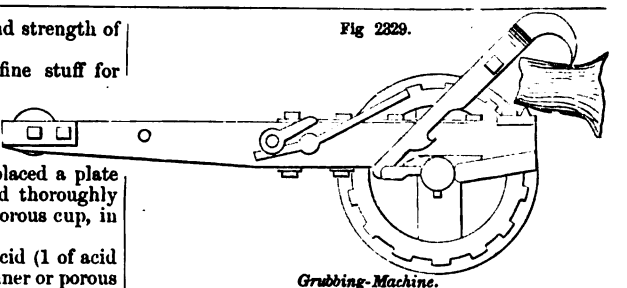
Kirkwood's Grubber (Scotch).

the land to a state of fine tilth, acting as substitute for the plow in some cases. It is more the practice in Britain than in the United States to give several successive plowings to ground in the course of one season, before sowing the seed. The grubber and some others of the heavier forms of cultivators are thus used. We apply the tool to the crop principally; they to that purpose, and also to the land, stirring it to bring it into good order and tilth before sowing.

The grubber represented has a frame of a general triangular shape, having teeth set in divergent rows. It has a caster-wheel in front and two wheels behind. The machine is adjusted vertically, by means of depressing the handles, which oscillate upon the hind axle and raise the share frame, being attached to a transverse bar across the frame near the rear and to the lever in front, which forms the carriage of the caster-wheel. This is a highly respectable implement.

The term "grubber" is somewhat local, and other implements of similar construction and purposes are described under CULTIVATOR (which see).

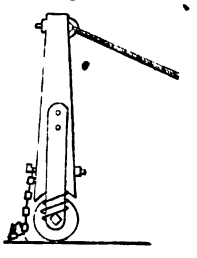
Fig. 2329.



Grubbing-Machine.

b. A machine or tool to pull *grubs;* that is, stumps and roots of bushes, saplings, and small trees. Some heavy plows are made to tear through ground occupied by the stubs and roots of bushes and brush. The English *turnwrest plow* is adapted for tearing through and routing up the roots of bushes. The grubber shown at Fig. 2329 has a lever supported upon an axle and wheels. When in vertical position it is attached by a grab hook and biting tooth to the stump, the lever is then pulled over by a rope or tackle, as seen in the smaller figure (Fig. 2230), where a post, roller, and chain constitute the apparatus. The pole is attached by the hounds to the axis of the rollers when being transported, but presses directly on the periphery of the roller when in action.

Fig. 2330.



Grubber.

Grub'bing-axe. An implement having a curved bit presented at right angles to the helve, like an adze; and another bit presented in the line of the helve, like an axe. A *mattock.*

Grub'bing-hoe. A heavy hoe for digging around stumps or stones. A mattock.

Grub-saw. A hand-saw used for sawing up marble slabs into strips, such as shelves, mantelpieces, etc. The kerf is started by a narrow chisel

Fig. 2331

Grub-Saw.

while lying upon the rubbing-bed. It has an iron blade notched at the edge, and stiffened by a backing of wood like the metallic back of a tenon-saw.

Grunt'er. (*Brass-founding.*) An iron rod, with a hook at the end, by which an assistant aids in supporting the crucible, by catching hold of the shoulder of the crucible-tongs.

Gua'no-sow'er. Guano is the excrement of sea-birds collected in thick beds on some islands on the coast of Peru, and in some other places. Its use is no new thing. The Peruvians before the conquest used guano in the cultivation of the potato, tobacco, corn, and other plants for which Europe is indebted to this side of the Atlantic. An English cruiser in 1720 mentions having captured a small vessel laden with it.

The guano-sower is sometimes an attachment to a wheat-drill, and does not differ very materially from a seed-sower, except in devices to keep the stuff stirred up and prevent its becoming aggregated in lumps.

Digitized by Google

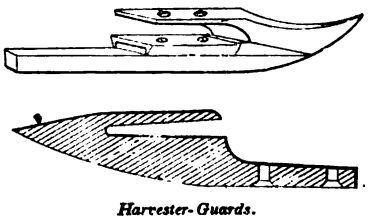
Guard. 1. An upright piece of wood in a narrow passage to prevent the lock of a canal or the corner of a street from being injured by passing boats or vehicles. A *fender*, *guard-pile*, or post, as the case may be.

2. (*Navigation.*) An extension laterally of the deck of a river steamboat, beyond the lines of the hull, making it overhang the water. It frequently comes flush with the outside of the paddle-box.

3. (*Machinery.*) A light frame in which the nuts of bolts fit to prevent their unscrewing by the vibration of the engine.

4. (*Husbandry.*) One of the teeth projecting forward from the cutter-bar of a harvester. The knife plays through the guards, and the knife sections

Fig. 2332.



Harvester-Guards.

make a shear cut against the soles *B* of the guard-slots. In the upper figure the sole-piece is removable to enable its edge to be sharpened.

5. The bow or basket of a sword-hilt to protect the hand.

6. (*Fire-arms.*) *a.* A bow beneath a gun-stock protecting the trigger.

b. A safety-lock of a fowling-piece to prevent the accidental dropping of the hammer.

c. A nipple-shield to protect the little tube which receives the percussion-cap.

7. A bow or wire around a lantern to protect the glass.

8. (*Bookbinding.*) One of the slips of paper bound in with a blank-book to thicken it at the back, when the leaves are intended to contain mounted slips, or drawings.

Guard-fin'ger. One of the teeth projecting forward from the cutter-bar of a harvester, and through which the knife plays. See GUARD.

Guard-lock. (*Hydraulic Engineering.*) A *tide-lock*, forming a communication between a basin and tide-water.

Guard-pile. (*Maritime Construction.*) A pile of the nature of a *fender*, driven in front of a quay or wharf to protect the structure from the blows of, or abrasion by, a vessel alongside.

Guard-plate. The plate which closes the opening in front of a cupola-furnace, to whose iron casing it is attached by staples. In the center of the plate is the *tapping-hole*, through which the melted metal flows when the *stopping* is withdrawn.

Guard-rail. (*Railroading.*) 1. A short rail placed on the inside of a main rail, so as to keep a wheel on the track by pressing against the inside of the flange of the wheel. It is used when there is a short break in the continuity of the other rail, as in switches and crossings. A *safety*, *side*, or *wing* rail.

2. (*Nautical.*) *a.* A hand-rail on the paddle-box bridge of a steam-vessel.

b. A breast-rail on the break of the poop.

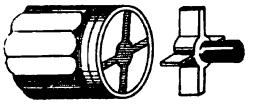
3. A safety-rail around a hatchway.

Gud'geon. *a.* The metallic journal piece let into the end of a wooden shaft.

b. The bearing portion of a shaft.

c. The metallic eye bolted to the stern-post to hang the rudder upon.

Fig. 2333.



Gudgeon.

The rule for finding the size of the gudgeon of a timber water-wheel is as follows: —

Multiply the diameter of the wheel in feet by the width of the wheel in feet, add to this the square of half the diameter of the wheel in feet. The cube root of the sum thus obtained will give the required diameter in inches.

Guest-rope. The rope by which a boat is kept steady while in tow.

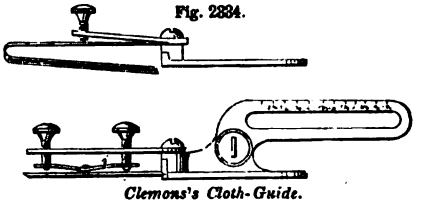
Guide. 1. A tool or instrument director, as the staff or director of a surgeon's probe or bistoury.

2. A pile driven to mark a site.

3. A pulley to direct a band in a new direction.

4. (*Sewing-machines.*) A means of directing cloth to the edge or face-plate of a gage, in making a hem or tuck.

Fig. 2334.



Clemons's Cloth-Guide.

In the example, the elastic plate is attached to the gage-plate and rests upon the goods, an adjustable pressure being brought upon the elastic plate by a screw or screws in a rigid plate above, and in such a manner that it presses more upon the cloth outside of the seam than inside, and so directs the cloth against the face of the gage-plate.

5. (*Railway Engineering.*) An additional rail to keep a locomotive or car on the track in curves, crossings, or steep grades. See GUIDE-RAIL; GUARD-RAIL.

6. (*Steam-engine.*) One of the bars which keep in line the blocks on the cross-head of the piston-rod. See GUIDE-BLOCK.

7. (*Printing.*) A printer's copy-holder, which marks the line.

8. (*Water-wheels.*) A plate in the curb of a water-wheel to direct the water upon the buckets of the wheel.

Guide-blocks. (*Steam-engine.*) Metallic pieces with parallel sides fitted on the ends of the cross-head and sliding as guides on the side frames to keep the motion of the piston-rod direct.

Guide-pile. (*Hydraulic Engineering.*) A pile driven to mark out or limit the field of operation or a site.

Guide-pul'ley. (*Machinery.*) A pulley for directing or changing the line of motion of a belt, but not otherwise concerned in the transmission of motion.

Guide-rail. An additional rail, usually placed midway between the two ordinary rails of a railway track, and employed in connection with devices on the engine, carriages, or both, in preventing the rolling-stock from running off the track.

The *center-rail* gripped by horizontally rotating wheels acts as a guide-rail.

Blenkinsop's rack-rail (English patent, 1811) was used as a means of progression in connection with a spur-wheel on the engine, and not as a guide.

Following him was Snowden's middle-rack and mechanical horse. See CENTER-RAIL.

Digitized by Google

Easton's center-rail (English patent, 1825) fulfilled two purposes; its upper edge formed a rack and served, in connection with a spur-wheel on the locomotive, as a means of progression; its sides formed a guide-rail in connection with pairs of horizontally rotating rollers underneath the carriages of the train.

Kollman's English patent of 1836 has a similar guide-rail.

Prosser's guide-wheels (English patent, 1844) are set an angle of 45° beneath the truck, and have sunken rectangular faces which bear upon the inner angles of the square rails. The guide-wheel enables the flanges of the bearing-wheels to be dispensed with.

No extra rail is introduced.

The *guide-rail* gripped by horizontally rotating wheels, driven by the engine, the combination of wheels and center-rail forming the means of ascending gradients, is first found in the English patent of Vignolles and Ericsson, 1830.

Sellers's United States patent, 1835, has a similar device, and it is also used by Fell on the White Mountain Railroad in New Hampshire and the Mt. Cenis Railway, which climbs the Alpine pass, connecting St. Michel on the French side with Susa on the Italian.

A correspondent of the Hartford "Courant" thus describes it:—

"The carriages are about half the length of ours at home, with seats on each side, so that the passengers face each other as in an omnibus, and with windows at the sides, from which it is difficult to see out when one is squeezed in tight on the seat, with his back to them. The cars are also very narrow, the track being only three feet six or seven inches gage, so that they are not much more comfortable than an omnibus. The fare, first class, was twenty-five, second class, twenty-two francs, from Susa to St. Michel, the time occupied in the passage being from four to five hours.

"The locomotives of these trains are small, compact, and powerful; their trucks, as well as those of the carriages, set well in the middle, so that they can turn very short curves. The track has three rails, one elevated in the center. Besides its ordinary driving-wheels, the locomotive has two horizontal wheels which press this third rail on either side, and it is by this strong traction that the train is pulled up. The carriages have corresponding wheels for the center rail, but their only use is to keep the train on the track. Both cars and locomotive have double sets of brakes, one for the ordinary and one for the central rail, so that they can screw the cars to the track with the grip of a vise, and render it almost impossible for the carriages to run away. There is every precaution against accident; and I should only fear the snow-storms of winter, and perhaps an avalanche in some places high up, which are not roofed in.

"Our train seemed to be a huge live reptile with legs and claws, that crawled up by its own power; it literally dug right up hill, and we felt ourselves mounting, and, looking back, could see the deep incline. On the curves, where the wheels got a good grip of the rail, we moved with ease and more rapidly than on a straight pull, where the locomotive evidently labored more, and we rose more slowly. The steepest grade on the road is one foot in nine feet, but this is only for short distances. The rise of one in twelve is more common; and the least (of which any note is taken) is one in twenty-five. The curves are so short as to be startling. We seemed to turn in a space as small as an ordinary wagon could. The shortest curves are on a radius of only one hundred and twenty feet; that is, our train would run round a circle only two hundred and forty feet in diameter. Our track was all the time in sight, behind and before, running along the steep hillsides, and constantly doubling, like a compressed letter S."

Gui'don. A swallow-tailed company flag in a cavalry regiment, half red and half white, dividing at the fork. The red above has "U. S." in white. The white is below, and has the letter of the company in red. The *fly* is 3 feet 5 inches to the end of the tail; the *head* is 27 inches. The lance is 9 feet long, including spear and ferrule.

The regimental cavalry flag in the United States service has 29 inches *fly* and 27 inches *head*. The edge has a yellow silk fringe. The field is of silk, and has the arms of the United States embroidered in silk on a blue ground, with the number and name of the regiment in a scroll under the eagle.

Guil-loche'. (*Architecture.*) An ornament of intertwisted bands or interlaced cords, which is made continuous as a fascia.

Guil'lo-tine. A machine for beheading persons, named after Joseph Ignace Guillotin, a French physician (1738–1814), its supposed inventor. He did not invent it, but seeing that his Revolutionary friends had a large job of killing on hand, he suggested its use as a certain and complete mode of decapitation.

Dr. Antoine Louis, of Paris, had the credit of its invention for a while, and it appears under the hands of the facile French to have attained a completeness in construction and execution which left nothing to be desired — except, perhaps, mercy.

A beheading machine, called the *maiden*, and sometimes the *widow*, by the *lively* Scotch, was imported from Halifax, England, into Scotland, about 1550, by the Regent Morton, who seems to have been enamored of the maiden's business capacity. He was beheaded thereby in 1581, — though he was not the first victim, as has been sometimes stated. The murderers of Rizzio were beheaded by it in 1566; and among its last victims was the Earl of Argyle, 1681.

It is laid up as a memorial in the Museum of the Scotch Society of Antiquaries, Edinburgh.

Of the Halifax machine we know but little except that Morton imported the maiden thence.

Pursuing the back track, we find that the Duc de Montmorenci (blue blood) was executed by a falling axe at Toulouse, 1632; that the Dutch used it in executing slaves in their colonies, and that its use was comparatively common in Germany during the Middle Ages.

The *Mannaia* of Italy, by which Conradin of Swabia was executed, 1268, at Naples, and Beatrice Cenci at Rome, in 1605, was of the same construction substantially.

The guillotine is mentioned in German books of 1534, 1551, and 1570. It is called the Roman falling-axe, and the decollation of St. Matthew thereby was a favorite subject with illuminators of manuscripts 250 years before the French Revolution.

In the London "Monthly Magazine," April 1, 1800, p. 247, is an enumeration of ten cuts and engravings of the sixteenth century in which a guillotine is employed. The representations are principally martyrdoms of saints.

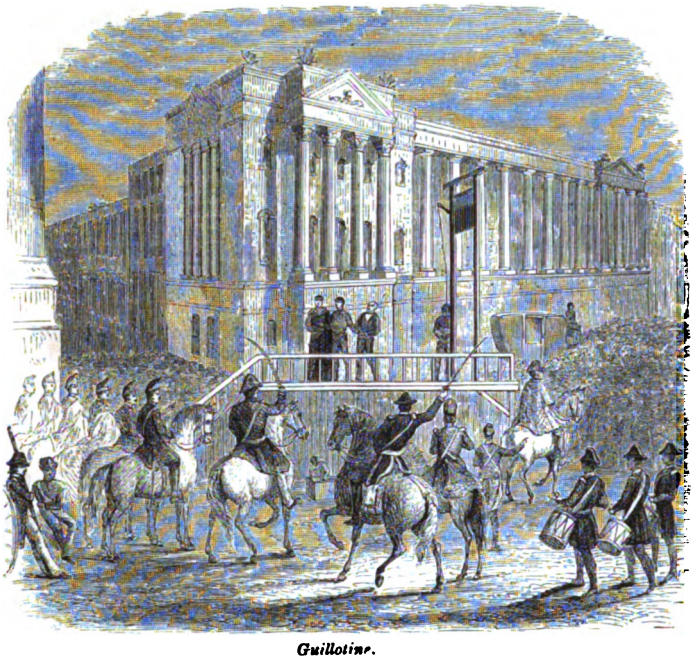
During the war of the Spanish Succession, 1702–13, Count Bozelli was decapitated by the guillotine, which is thus described by a traveler who witnessed the act:—

"In the great square was erected a scaffold, covered with black. In the middle of it was placed a

Digitized by Google

great block of wood, exactly of such hight that the criminal, on his knees, could lay his head upon it, between the pillars of a sort of gallows, which supported an axe of a foot in hight and a foot and a half in breadth, sliding in a groove. The axe had a mass of above a hundred weight of lead attached to its upper side, and was suspended by a cord fastened to the gallows. The executioner cut the cord that supported the axe. The deadly instrument in its fall severed the head from the body, and penetrated about two inches into the block."

Fig. 2335.



Guillotine.

The original instrument was probably Persian.

The French *guillotine* has a heavy knife, sliding in vertical grooves in a frame.

It is a grim subject, but, involving mechanical construction, is within our scope.

An observer in Paris thus records the appearance of the machine and the mode of using it: —

"On a platform about 12 feet square, and 7 feet above the ground, are erected the two upright posts between which is suspended the axe. They somewhat resemble a narrow gallows with not more than a foot between the posts. The axe, which is not unlike a hay-knife, though much heavier and broader, is drawn up to the top of the posts, between which it runs in grooves, and is held suspended by a loop in the halyards, passed over a button at the bottom. The edge of the axe is diagonal, so as to make a *draw* cut, giving it a fearful power and certainty in severing a human neck.

"On the center of the platform stands a frame or large inverted box, much resembling a soldier's arms-chest, about 6 feet long and 2½ feet wide and high. One end of this abuts upon the upright posts; at the other end is a small truck having a strap and buckle by which the culprit is secured to it.

"The victim was advanced with his breast against the truck, to which his body was rapidly strapped. He was then tilted down, truck and all, upon his face; the truck, moving upon small wheels in grooves on the top of the chest, was run rapidly forward until the neck came under the knife. The rope was unhooked from the button, the axe fell with a *thud*, the head fell into a basket, and the body was unstrapped and rolled into a large basket alongside."

There is an air of ferocity about the punishment by beheading, and of absolute brutality in the mode of execution by hanging. The Japanese are skillful decapitators. The Spanish garotte is a horror. Poisoning is ancient but disreputable. Shooting is martial, and has one merit; it enables a man to stand up and face the executioner, and has less of humiliation than the cutting and choking processes.

It is a vulgar error that Dr. Guillotin perished by the machine of his suggestion. He died in 1814, after founding the Academy of Medicine.

The myth seems to have been derived from the Regent Morton's having been beheaded by his imported pet. This kind of poetic justice is commoner in tradition and romance than in fact. It seems to round up and complete the history when —

"This even-handed justice
Commends the ingredients of our poisoned chalice
To our own lips."
"Where the offence is let the great axe fall."

Guil'lo-tine'-cut'ter. A machine which cuts by a knife descending in guides. Cutters for paper and straw are thus made, and the descent is usually oblique, so as to give a *draw* cut.

Gui-pure'. A kind of lace in imitation of the antique. Patterns are cut out of cambric to form the flowers and heavy parts; the open parts are made of stitches.

Gui-tar'. The ancient Egyptian guitar (*a*, Fig. 2336) had a hollow, oval body, and its upper surface was perforated for the escape of the sound. It had three strings of catgut, fastened at the lower end to a triangular piece of wood or ivory which raised them to a sufficient hight without a bridge. The guitar was played as an accompaniment to the voice and in concert with other instruments. Also in concert with dancing motions and posturing, which is about as near as the Egyptians came to theatrical performances. These were invented by the Greeks, the originators of tragedy and comedy. The Romans added the pantomime.

On the Guglia Rotta at Rome is a large obelisk, which was brought from Egypt by Augustus and thrown down and broken at the sacking of the city by the Constable of Bourbon, in 1527.

On it is represented a guitar (*b*) which had evidently two strings. The length of the finger-board would allow a considerable scale of notes.

In the sculptures of Nimroud is represented a musician playing on a guitar.

The present name is derived intermediately from

Digitized by Google

the ancient Greek, where it indicated a musical instrument resembling a harp (*cithara*).

The Europeans, ancient and modern, derived it from Egypt. Like some other things, it was imported directly into Greece from Egypt in ancient times; and again through the intervention of the Saracens into Europe, after the lull of the dark ages; following the track through Spain.

The modern Arabs have an instrument called the 'ood (*c*, Fig. 2336), which may be considered the Syrian guitar. The head is bent over as in the Euro-

Fig. 2336.

Guitars.

pean guitar; the neck appears to be destitute of frets. The strings are seven, and are made of catgut.

The Peruvians had a guitar with five or six strings, called a *tinga*. They also possessed the *syrinx*, *flute*, *tambourine*, and *trumpet*.

The guitar was introduced into England by Francis Corbeta, about 1660, and was a novelty to the writers of the day.

"I heard a Frenchman play upon the guitar most extreme well, though at best methinks it is but a bawble." — PEPYS's *Diary*, 1661.

"My Lord Sandwich playing upon the gittarr, which he now commends above all musique in the world" — PEPYS's *Diary*, 1665.

The guitar is the principal musical instrument of the Japanese. Their *syamsie* has three strings, two in the octave, the middle one giving the fifth. It is played with a plectrum, consisting of a flat piece of horn, held between the thumb and third finger. The Japanese have no idea of harmony, and play all their instruments in unison. Their dancing is of the Oriental style, like the Almehs of Egypt, — motions of the arms, head, and body, rather than of the feet. It is not so exclusively professional as in Egypt and India, and consequently not so systematically lascivious.

The Spanish guitar *d* has a hollow body with a round opening in the sounding-board. The neck has seventeen frets. The strings are six, are tuned E, A, D, G, B, E, and are stretched between a bar attached to the sounding-board and the pegs, which are journaled in the *head*.

An English guitar has been constructed to be touched by keys, and one of a large size has been made in Germany, and is adapted to be held with the bow between the knees. Neither have proved valuable accessions to the list of musical instruments.

Gui'tar-ban'jo. An instrument combining the characteristics of the guitar and the banjo, having the strings and fretted neck of the former, and the sheepskin head and metallic hoop of the latter.

Gul'let. 1. (*Civil Engineering.*) A narrow working cutting made in the formation of an excavation, and used as a means of laying down a pair of rails to bring the dirt-cars to the bank.

2. (*Harness.*) The lower end of a horse-collar, around which passes the *choke-strap*, and the *breast-strap* which supports the pole of a carriage.

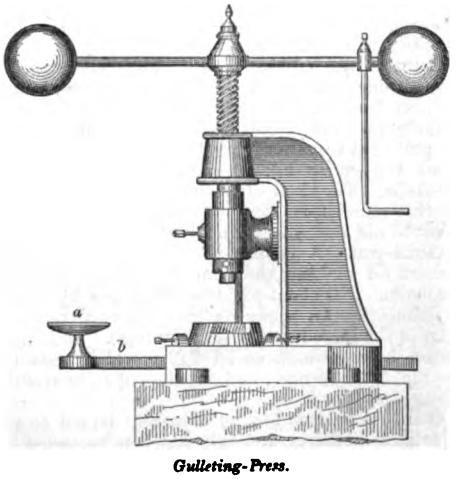
3. (*Saws.*) A hollow cut away in front of each saw-tooth, in continuation of the face, on alternate sides of the blade. Such saws are known as *gullet-saws* or *brier-tooth saws*.

The gullet is adapted to allow the saw to be sharpened by a round or half-round file, by which the face of the tooth becomes concave when viewed edgeways, and acquires a thin cutting edge. The increased curvilinear space also allows more room for the sawdust. See GULLET-SAW.

Gul'let-ing. (*Railroad Engineering.*) In excavating for railroads, a system of carrying the work forward in a series of steps upon which different gangs of men are at work with pick, shovel, and wheelbarrow, assisted by temporary lines of rail and dumping-wagons if the work be sufficiently extensive. Also called *notching*.

Gul'let-ing-press. A press for punching or gulleting saw-blades, gumming worn saws, or paring

Fig. 2337.



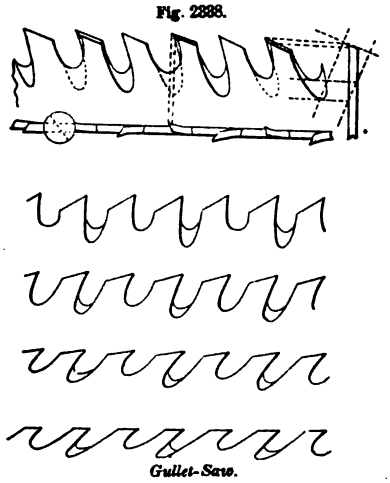
Gulleting-Press.

down or retoothing broken saws. The punch is socketed in the end of a plunger whose upper portion is a double-threaded screw crowned by a fly-handle. The table *a* is adjustable by means of its rod *b*, and affords an axis for the eyes of circular saws or saw-blades under treatment.

Gul'let-saw. A saw having a hollow cut away in front of each tooth in continuation of the face and on alternate sides of the blade. Called also a *brier-tooth saw*.

Digitized by Google

Fig. 2888.



Gullet-Saw.

Gul'let-tooth. A form of saw-tooth. See GULLET-SAW.

Gul'ley. The tram-plates or rails laid for the use of tram-wagons.

Gum. 1. An instrument for shaping saw-teeth. See SAW-GUMMER.

2. A hive made of a section of a hollow log; a *bee*-gum.

3. A hollow log inserted vertically into the ground as a curb for a spring.

4. A vegetable secretion which hardens as it exudes, but is soluble in water; distinguished from resins, which are soluble in alcohol, but not in water. There are a few resins which by careless custom are named as gums, such as *copal*, often called *gum-copal*.

Gum'mer. A tool or machine for deepening and enlarging the interdental spaces of worn saws. See SAW-GUMMER; GULLETING-MACHINE.

Gum'ming. (*Lithography.*) The treatment of a lithographic stone with a solution of gum-arabic, after, or simultaneously with, the etching process, whereby the clean parts of the stone devoid of work are protected from receiving fatty matter, and thus reject the greasy ink when the roller passes over the stone. The clean surface of the stone is damped between each impression, but, without the gumming, it would not permanently resist the ink.

Gum-pot. A copper boiler used by varnish-makers for melting the gum and mixing the ingredients. It is about 33 inches deep, and 9½ inches in diameter. An upper section is riveted to it to keep in the ingredients when they foam. It is supported by a circumferential flange which rests on the top of the furnace, and is adapted to be readily removed and replaced.

Gun. A weapon having a barrel adapted to receive and discharge a missile which is projected by a charge of powder, gun-cotton, or air, as the case may be. See under the following heads: —

Air-gun.	Fire-arm.
Arquebus.	Fowling-piece.
Battery-gun.	Gatling-gun.
Blunderbuss.	Howitzer.
Cannon.	Machine-gun.
Carbine.	Magazine-gun.
Carronade.	Mitrailleur.
Columbiad.	Musket.
Field-gun.	Pistol.
Pivot-gun.	Siege-gun.
Revolver.	Swivel-gun.
Rifle.	Steam-gun.
Shot-gun.	

Allied are another class not usually termed guns.

Mortar.	Coehorn.

The projectiles are numerous. Lists may be found under WEAPONS; PROJECTILES; FIRE-ARMS; ARTILLERY (which see).

Gun-bar'rel. Gun-barrels of superior quality are known as *stub*, *stub-twist*, *wire-twist*, *Damascus-twist*, *stub-Damascus*.

Stub-iron consists of horseshoe nails, cleaned in a tumbling-box, mixed with from 12 to 50 per cent of steel pieces of the same size; puddled, hammered, heated, tilted, and rolled. From this material a *skelp* is made.

Twist barrels are made of a ribbon of iron wound spirally around a mandrel and welded.

Stub-twist is stub-iron coiled on a mandrel, as described.

Wire-twist is made by welding laminæ of iron and steel together, or two qualities of iron, and drawing the compound bar into a ribbon, which is coiled as described.

Damascus-iron is made of several bars of steel and iron laid parallel in a *fagot* and drawn out into a bar. A piece of the bar is heated to redness, one end placed in a vise and the other end grasped by tongs, by which the bar is twisted till it assumes a cylindrical shape, and is shortened to, say, three feet. Several such bars, twisted in diverse directions, are laid together, welded, and drawn into ribbons, which are severally wound on mandrels as before.

Stub-Damascus is formed from a single bar or twisted rod, forged, drawn into a ribbon, and wound on a mandrel.

Damascus and wire twist is ribbon of the said varieties combined.

The ribbon for the twisted barrel is several yards long, about ½ inch broad, and is thicker at one end than the other, in order to give the strength at the breech. It is heated to redness, coiled around a mandrel, the coil removed, heated to welding heat, dropped on to a cylindrical rod which is then struck vertically on the ground to jar the edges of the spiral together and cause them to adhere. This is called *jumping*, and the operation of welding is completed by a hammer on an anvil, the central rod being maintained in position.

The iron plate, technically termed a *skelp*, is usually about a foot in length, and when heated to a welding temperature is rolled around a mandrel and passed through sets of rollers, which, in turn, elongate the skelp, reducing its diameter and giving the proper size and taper to the barrel.

Formerly the edges of the heated blank were welded upon the mandrel by the successive blows of a trip-hammer, or a "drop," dies intervening between the iron tube and the drop and anvil respectively. A portion only of the seam is closed at a time by this means, and the operation is more tedious and expensive than the rollers just described. The rolling process was introduced from England.

(*Boring.*) For boring, the barrels are placed in a heavy iron frame called "boring banks," where they are reamed out by the boring-tool, which consists of a square broach of steel, with sharp edges. The tool is rotated and advanced while the barrel is firmly held, and the operation is repeated with successively larger tools until the required size is obtained, — something short of the eventual caliber, as

Digitized by Google

other operations are to follow, and will farther increase the size of the bore.

The outer surface of the barrel is then turned in a lathe, the barrel being sustained by mandrels at each end. The tool may be fixed in a slide-rest which moves it longitudinally of the barrel, and also in or out to give the required taper from the breech to the muzzle, or the latter or transverse motion may be imparted to the tool-rest while the barrel has a longitudinal in addition to its rotary motion.

The barrel is then ground by being held parallel to and against the face of a rapidly revolving stone. For this purpose the barrel is slipped upon an iron rod and revolved by means of a crank on the end of the rod. The stones are cased in for safety, and also to keep the water from splashing upon the workmen, holes in the ends of the casing permitting the introduction and withdrawal of the barrel.

After grinding, the barrels are polished by hard-wood rubbers, supplied with lard-oil and emery. The barrels are placed in upright frames, several in each frame. The grooved ends of the rubbers are then pressed by springs against the barrels as they move up and down with a regular and rapid motion, the barrel, the while, revolving slowly. After remaining in the first polishing-machine for fifteen minutes or thereabouts, they are transferred to another and similar apparatus where the emery is dispensed with.

Much ingenuity has been expended in devices for detecting deflection or faults in gun-barrels, and for straightening them when unevenness is detected. The correction is made by placing the barrel on a small anvil and giving it a gentle blow with the hammer. The workman obtains artificial aid in detecting faults, by a transparent slate marked with two parallel lines and placed in a window. The barrel being pointed towards the window, the lines are reflected upon the polished interior surface of the barrel, and any unevenness throws the reflected lines out of parallelism; which is readily detected by the experienced workman. In former times, a hair or some other very slender line was passed through the barrel and drawn successively across each portion of the inner surface, concavities being revealed by the distance between the line and its reflected image in the metal.

For proving, the barrels are loaded with a heavy charge and then laid in a rank in the parallel grooves of a massive table in the proving-room, the charge in each piece being connected to a train of powder on the back of the stand, and passing to the outside of the building, so as to fire the charges from a place of security. The balls are received in a bank of earth, and those barrels which appear to have withstood the first charge are subjected to a second, smaller proving charge, to open any rent which may have been made by the former. Those which stand both tests are stamped with the mark of approval.

A still more severe test is filling the barrel with water, and driving in an air-tight bullet by heavy and repeated blows. If any chink or crack is to be found, the water will ooze from it.

The barrel having been welded, rolled, bored, turned, ground, polished, and proved, is now to be rifled by having twisting grooves cut in its interior. This is more fully referred to in this work under RIFLING-MACHINE, and is a very old device, specimens of rifled cannon and small-arms of the seventeenth century being preserved in European collections. In general features most of the machines agree; the barrel is firmly secured in the frame of the machine, and the grooves on its inner surface are cut by narrow bars of steel, which are placed within three apertures near the end of an iron tube which passes through the barrel by a slow compound motion, rotary and progressive.

The sight and cone seat are attached to the barrel at the proper stage of its progress, the former by brazing and the latter by welding.

Steel barrels are drawn from short bars, which are bored, heated, and drawn upon a mandrel between rolls, which successively lengthen and reduce the diameter of the barrel.

After boring and rifling, the grain or mottled appearance is produced by steeping in acids or by heating in boxes with charcoal, and then plunging in solution of ammonia. See BROWNING.

The principal imperfections to which gun-barrels are liable are the *chink*, the *crack*, and the *flaw*.

The *chink* is a small rent in the direction of the length of the barrel.

The *crack* is an imperfection across the barrel.

The *flaw* is a scale, or small plate, adhering to the barrel by a narrow base, from which it spreads out like the head of a nail from its shank, and when separated leaves a little pit in the metal which collects moisture and foulness, corroding the metal.

Gun-bar'rel Gage. The gage of large guns is the weight of the ball they carry, as 6-pounder, 8-pounder, 12-pounder, etc.

Or it is expressed in inches, and the fraction, if such there be, in decimals, as 8-inch, 10-inch.

The bore of the barrels of fire-arms is also denominated by the decimals of an inch, as .44, .45, .50, .55; all of which are somewhat common sizes.

The usual mode of denominating the barrels of sporting-rifles and fowling-pieces is by the number of bullets, of the diameter of the bore, that are contained in one pound of lead.

Gage-Table for Barrels of Fire-Arms.

No.	Diameter of Bore in 100ths of 1 Inch.	Weight of Leaden Bullet in Grains.	No.	Diameter of Bore in 100ths of 1 Inch.	Weight of Leaden Bullet in Grains.

Gun-bat'ter-y. 1. (*Fortification.*) The emplacement of two or more pieces of artillery, destined to act on the offensive or defensive. It may be, —

Open; merely field-guns in position.

Covered; protected by a parapet.

Masked; disguised by a screen of branches, or other obstructions to the view.

Enfilading; sweeping the face of the body of troops or the works, by a fire in the line of the length of the object.

En echarpe; having a line of fire oblique with the face of the object.

En revers; playing upon the rear of the enemy.

Cross-fire; several batteries having a converging fire upon an object.

Digitized by Google

Siege; of a large description, for breaching.

a. Elevated; on the natural level of the ground.

b. Half-sunken; when the *parapet* is partly made of earth from the *terre-plein* or gun-platform.

c. Full-sunken; when the *terre-plein* is farther lowered by taking all the earth therefrom to form the *parapet.*

Casemate; when protected by a bomb-proof chamber and firing from *embrasures.*

Barbette; firing over a parapet.

Breaching; devoted to making an opening in the wall of a fortification.

Ricochet; when the balls, with a low charge, traverse the inner face of the enemy's works and rebound and roll along the same.

Mountain; light pieces adapted to be dismounted, and, with their dislocated carriages, carried on mules.

2. (*Field-artillery.*) The tactical unit of field-artillery. A certain number of field-guns under one command, together with the officers, men, horses, wagons, and stores.

An English field-battery has six 12-pounder, Armstrong, breech-loading, rifled guns. Each gun has its limber, and the battery has 22 other carriages and 210 horses. It is officered and manned by two captains, three lieutenants, and 236 non-commissioned officers and men.

Three field-guns to 1,000 men is the usual proportion in European armies.

Gun'boat. A small vessel of war, carrying from one to four guns if sea-going. Gunboats in the United States Service are usually fourth-rates. See IRON-CLAD.

The gunboats employed for river service by the United States government during the late civil war were generally flat-bottomed, side-wheeled craft, of light draft, and partially iron-plated above the water-line with from two to four inches of iron, backed by eighteen to thirty inches of oak, set at an incline of 55° or thereabouts. The strongest plating was forward, and when these vessels could fight "bow on" they were considered invulnerable to 64-pound shot. They carried from four to sixteen guns, which were fired through portholes. (See illustration on opposite page.)

Auxiliary to the gunboats was a fleet of steam-rams, built especially for speed, and calculated to run down and sink an enemy. They generally carried one gun.

Gun-car'riage. The apparatus upon which a cannon is mounted for service. It may or may not be adapted for the transportation of the piece.

The first consisted merely of a timber-block, or frame, to which the cannon was secured by straps or bolts. Uprights, with holes for pegs, were sometimes employed to give elevation to the muzzle. Afterwards a species of trough, having a butt-piece and mounted on wheels, was introduced (*A*, Fig. 2339). Subsequent improvements brought them nearly to the form *B*, which represents a carriage of the Gribeauval pattern. Gribeauval, a French artillery officer, made great improvements, 1765, in gun-carriages and the organization of artillery, reducing the size of the parts, and making the similar parts, for those of the same class, interchangeable; he also added a tongue, so that two horses could draw abreast, and made the limbers so that one sort would answer for several different kinds of carriages.

Land gun-carriages comprise field, siege, casemate, and barbette carriages. The two former are adapted for the transportation as well as service of the piece, while the latter are intended to be kept in one position in a fortification. A smaller kind of field-carriage may be readily taken to pieces and put together, so as to be carried on mules' backs in a rugged and mountainous country.

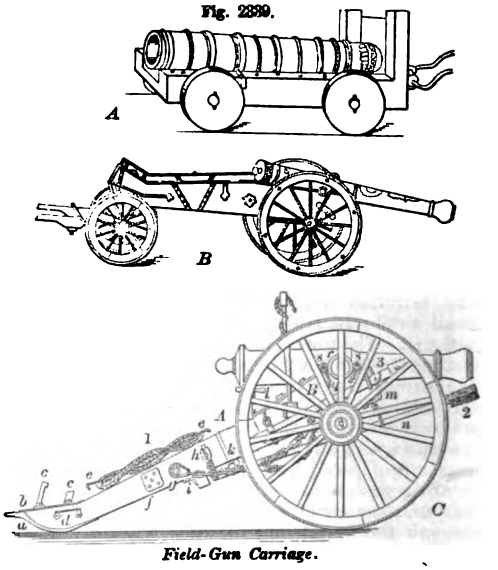
Field-carriages include those which are adapted to accompany the movements of troops during an engagement, and carrying a class of guns weighing from 800 to 1200 pounds, as the 12-pounder smooth-bore and lighter rifled cannon.

These carriages are known as "stocktrail" pattern, from having a single piece, which serves as the trail, inserted between the two cheeks on which the trunnions rest.

The Gribeauval and older patterns of carriage had no stock, the ends of the cheeks resting immediately on the ground; the fore-wheels were also smaller than the hinder.

C is an elevation of a field-gun carriage without its limber. The various parts are, —

Fig. 2339.



Field-Gun Carriage.

A, stock.
B, cheek.
a, lunette.
b, trail-plate.
c c, pointing rings.
d, handle.
e e, prolonge hooks.
f, wheel-guard plate.
g, lock chain, bolt, nut, and washer.
h, turn-buckle, chain, and hasp for sponge and rammer.
i, stop for rammer-head.
k, ear-plate for worm.
l, elevating-screw.
m, under-strap.
n, implement-hook.
o, D-ring for hand-spike.
q, trunnion-plate.
r, cap-square.
s, cap-square chains and keys.
1, prolonge.
2, sponge and rammer.
3, hand-spike.

The detachable forepart of the carriage is called the limber. It carries a chest for containing ammunition, upon which the cannoniers sit. The limbers for all field-carriages differ only in the interior fitting up of the chest, adapting it for receiving different kinds of ammunition.

A *caisson* for carrying ammunition accompanies each field-piece. This vehicle has a limber similar to that of the gun-carriage. Its rear part, or body, carries two ammunition-chests, the three, with that on the carriage-limber, containing the full supply of ammunition for the piece.

Each field-battery of four or more pieces is also accompanied by a *traveling-forge* and a *battery-wagon,*

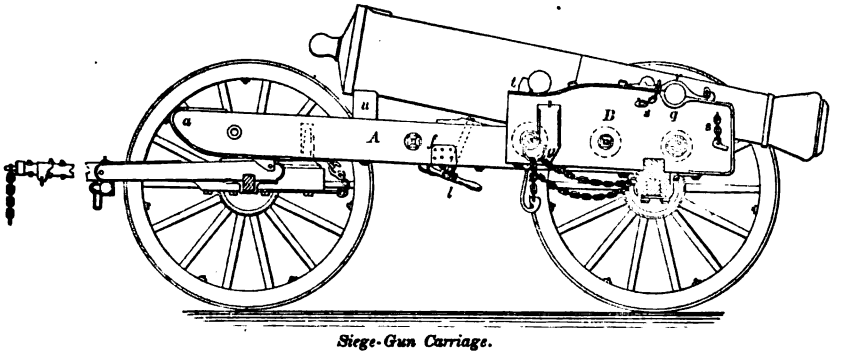
which contain the necessary tools and materials for ordinary repairs.

Each carriage is drawn by six horses, harnessed in a manner somewhat different from the ordinary way, the traces of the wheel horses being directly attached to the splinter-bar of the limber, and the traces of the leaders connected to those of the wheel-horses. Swingletrees and whiffletrees are thus dispensed with.

The siege-carriage (Fig. 2340), though larger and heavier than that for field service, differs little from it in general construction. For transportation the gun is moved backward, the trunnions resting against the head of the traveling trunnion-bolt *t*,

Fig. 2340.



Siege-Gun Carriage.

the breech supported on the bolster *u*. The small parts for holding the implements are wanting.

Three sizes are employed in the United States artillery service, one for the 4½-inch rifled gun, one for the 18-pounder smooth bore and 30-pounder rifled gun, and one for the 24-pounder and 8-inch howitzer.

Barbette carriages are intended for firing over the parapet of a fortification, and are adapted to mount guns of 32-pounder, 8-inch, 10-inch, 15-inch, and 20-inch caliber. The carriage proper rests on a frame called the *chassis*, which turns about a fixed pintle, so that it may be traversed to point wholly or partially around the circle. See BARBETTE.

Casemate carriages resemble the above in their general construction, but are somewhat less high in proportion. They are placed in casemates, where the gun is fired through an embrasure. See CASEMATE.

These two latter classes of carriages, and also mortar beds, have since 1860 been made of wrought-iron, which material has also been tried to some extent for field-carriages with a promise of good results. Cast-iron was at one time tried and found utterly unsuitable.

Ordinary broadside naval gun-carriages much resemble the army casemate carriage, but have no chassis. They are mounted upon four small wheels, called "trucks," and are run in and out and pointed by means of two *side tackles*, hooked respectively on the left and right to the side of the ship, and a *train-tackle* hooked to a ring-bolt behind the carriage. Excessive recoil is checked by the breeching, a stout rope passing through a hole in the cascabel of the gun, and shackled to the ship's ribs on either side. Elevation is given either by means of a graduated quoin or an elevating screw.

In the *Marsilly* carriage the two front rollers are wanting, the front transom resting immediately on the deck.

Light broadside guns and boat guns have their carriages arranged to run on slides corresponding to a chassis, and have compressors for moderating the recoil. Boat guns are also provided with field-carriages of iron in order that they may be employed on shore.

Heavy pivot guns as 11-inch, on upper decks, are mounted on a peculiar carriage, which enables them to be directed to any point around the circle by means of side tackles and *in* and *out* tackles hooked to bolts appropriately placed around the deck.

Very heavy guns, as 15-inch or 20-inch, being always placed in revolving turrets, their carriages need have no lateral motion, as this is obtained by the rotation of the turret itself, operated by connection with the engine of the ship. Devices similarly operated are also provided for loading. See BATTERY-FORGE, BATTERY-WAGON, CAISSON, BARBETTE-CARRIAGE, CASEMATE-CARRIAGE, MORTAR.

The necessities of modern warfare, land and marine, have given rise to many inventions for operating heavy guns and for the protection of those working them. For the latter purpose, besides mantelets and shields, arrangements have been made for rotating the turret in which the gun is mounted so as to cover the embrasure; depressing the gun during loading below the embrasure, etc.

For counterpoise carriages see: —

Brewer's gun-carriage, 1870, is supported on a platform which is supported by levers within a curb, and a weight suspended from the ends of the levers counterpoises the gun, carriage, chassis, and platform.

Callender and Northrup, 1864, have a platform supported by a piston in an air-cylinder beneath.

Eads (1865, 1869, and 1871) causes the recoil of the gun to depress it backwardly and downwardly, it being poised on its trunnions on the end of an arm which oscillates in an arc. As the gun descends, a piston traverses in a cylinder, compressing air therein, and the elasticity of the air assists in restoring the gun to its position when the loading is complete.

Coughlan, 1870, has a cogged segment and weighted toggle which allow the gun to depress by the force of recoil.

Taggart, 1863, has two guns on a cylindrical carriage which is on an axis reaching athwart the vessel. The gun beneath is in loading position below decks, while the one above is in firing position. The latter being fired, the axis is rotated and the guns change places.

Winans, 1865, lifts his gun, carriage, and traverse into firing position by steam piston and cylinder beneath.

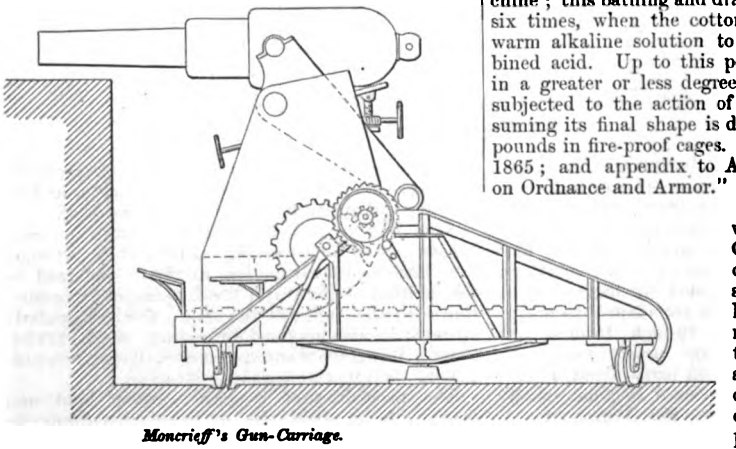
Digitized by Google

Houel and Caillet have a system of levers which oscillate backwardly by the recoil, and in so doing bring into action a spring which afterward assists in restoring the gun to firing position. See also Coon, 1863; Foster, 1869.

Wappich, 1863, has a toggle-joint and screw for elevation and depression. Also screws beneath the trunnions.

In Moncrieff's gun-carriage (Fig. 2341) the gun is supported upon a moving fulcrum, which, on the firing of the gun, is caused to shift nearer to the gun and farther from a counterweight, spring, or other force, while at the same time the gun is brought into a lowered position for reloading, and is then automatically raised into position for firing. By the shifting of the fulcrum, the statical momentum of the balance weight is made to preponderate so greatly

Fig. 2341



Moncrieff's Gun-Carriage.

over that of the gun that it will, when allowed free action, after the loading of the gun, raise the same into its original position.

For running the gun in and out of battery, and traversing and operating guns in turrets, see patent of Ericsson, 1866, 1870; Perley, 1865, 1867; Eads, 1864, 1865; Bartol, 1863. Training twin guns in parallelism in turrets, Eads, 1866.

Eads, 1864, 1865, has a means for training the gun upon an imaginary center, which is the center of the exterior opening of the port or embrasure, so as to reduce the opening to the smallest size.

Gun-cot'ton. The first notice of the discovery of gun-cotton was made by Braconnet, in 1833, who detailed the action of nitric acid on starch, sawdust, linen, and cotton. He called it *xyloidine*.

Pelouse, in 1838, called attention to this compound.

Dumas, in 1843, again cited a mode of preparing, and made suggestions for the application.

Schönbein, in 1846, brought forward his plan of using nitric and sulphuric acids. It was described by W. H. Ellet of Columbia, S. C., in 1846.

Baron Von Lenk, 1864, used cotton skeins instead of employing the wool in masses, thus rendering the saturation more complete and the manipulation easier. The loose cotton thread is first boiled in an alkaline solution and afterwards placed in a cylinder with perforated wire sides, making from 600 to 800 revolutions per minute, by which the alkali is expressed; it is then washed in clean water and again subjected to the action of the cylinder, after which it is thoroughly dried by exposure to air and by heating in a chamber to about 120°.

One-pound charges of the cotton thus prepared are next immersed in a mixture composed of 3 parts of sulphuric to 1 of nitric acid, which has been allowed to cool from 48 to 72 hours; the vessels containing the cotton and acid being surrounded with cold water to prevent undue heating during the chemical action which ensues.

The cotton is then placed on a strainer and expressed until it retains but about ten times its weight of acids, when it is removed to an earthenware jar, surrounded by water as before, where it is allowed to remain forty-eight hours to insure its complete conversion into "trinitro cellulose," or gun-cotton. It is then taken out and washed by plunging suddenly in water, to prevent heating; and afterwards placed in a tank of running water for forty-eight hours, and dried in the centrifugal machine; this bathing and draining process is repeated six times, when the cotton is finally washed in a warm alkaline solution to remove all the uncombined acid. Up to this period the cotton has been in a greater or less degree damp, since it was first subjected to the action of the acids, but after assuming its final shape is dried in charges of twenty pounds in fire-proof cages. See also Revy's process, 1865; and appendix to A. L. Holley's "Treatise on Ordnance and Armor."

Mr. Abel, of the Woolwich (England) Dock-Yard Chemical Department, has discovered that the explosive force of gun-cotton, like that of nitro-glycerine, may be developed by the exposure of the substance to the sudden concussion produced by a detonation, and that if exploded by that agency the suddenness and consequent violence of its action greatly exceeds that of its explosion by means of a highly heated body of flame.

Charges for sporting or blasting purposes are sometimes put up with a core of raw cotton, to diminish the force of explosion.

Wet gun-cotton is of course proof against explosion by heat, but it has been found that its explosive energy is rather increased than diminished when wet and fired by percussion. A body of gun-cotton thrown into the sea in a net, with a protected priming of dry cotton and fulminate, will explode with as much force as if confined in a water-tight vessel.

The rapidity with which gun-cotton detonates has been computed at 20,000 feet per second. Its energy is from two to four times that of gunpowder. See EXPLOSIVES.

Gun-cotton is not soluble in alcohol or ether, but in a mixture of the two it dissolves readily, giving rise to a perfectly colorless mucilaginous liquid, known as *collodion*. This dries quickly to a hard skin, quite structureless, and possessing considerable strength. It is used in surgery, and also, in conjunction with iodides and bromides, to form the collodion of the photographer. See PYROXYLINE.

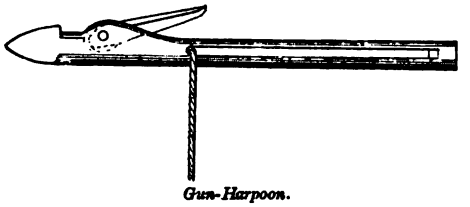
Gun-deck. The lower deck of a ship of war.

Gun-har-poon'. One fired from a gun, used mounted in a crutch on the gunwale of a whaleboat. It is made of steel, and has a chain or long-shackle attached to it, to which the whale-line is fastened. Some gun-harpoons carry a grenade or flask of poison which breaks and sickens the whale.

In the illustration, the harpoon has a hinged barb

Digitized by Google

Fig. 2342.



Gun-Harpoon.

and a slotted shank, in which is a sliding link to which the line is fastened. The rear end of the slot has an elastic guard to receive the shock of the ring as the harpoon is fired. See HARPOON.

Gun-lock. The combination of parts by which the propulsive charge is caused to ignite. The matchlock, the first known employment of which was at the battle of Morat, 1476, was the earliest known form. In this a piece of slow-burning cord was passed through a hole in the cock, which was thrown forward on pulling the trigger, bringing the lighted end of the cord in contact with the priming. The gun with this attachment was called an arquebus. It continued in use until the invention of the wheel-lock in Italy, about 1521. In this, a furrowed steel wheel was, by means of a spring and chain, caused to revolve in contact with a piece of native sulphuret of iron, producing sparks which ignited the priming. This mineral is said to have originally derived its name pyrites, or firestone, from having been thus employed.

The "snaphaunce" lock comprised a hammer carrying a flint, which was caused to strike against a furrowed piece of steel, which performed the office of the battery in the more modern flint-lock. It is said to have been contrived by German or Dutch marauders, to avoid the exposure attending the use of the matchlock in nocturnal expeditions.

The flint-lock is said to have originated in France about 1635, and its general features do not appear to have essentially changed in the two centuries, nearly, during which it was used to the exclusion of all others. The parts corresponded to those of the percussion-lock of the present day, except that the hammer was provided with a pair of jaws for holding the flint, which was caused to strike a pivoted lip called the *battery*, throwing it back and dropping a shower of sparks into the "pan" containing the priming.

In 1807 Rev. Mr. Forsyth obtained a patent in England for a fulminating powder, which was to be placed in a magazine at the breech of the gun and fired by a pin. Various modifications were devised prior to the introduction of the common copper cap, about 1816. This, however, made its way rather slowly. It was not until 1842 that the percussion lock and cap were adopted in the United States military service.

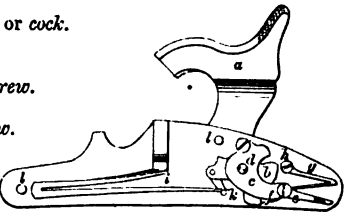
The adaptation of the flint-lock to cannon was easy, it being merely necessary to secure the lock in position by a ring around the breech of the gun; when the hammer fell back, on firing, the blast from the vent passed freely, without injury to the lock. It was otherwise with percussion-locks when applied to a vent two tenths of an inch in diameter. The shock of the blast would soon have destroyed such a lock without the hammer was withdrawn from over the vent at the very instant of firing. This difficulty was obviated by E. Hidden's lock, first patented in 1831 and subsequently improved.

In this, that end of the hammer to which the lanyard is attached is longitudinally slotted, so that the same pull which brings the hammer down upon the head of the primer withdraws it back a slight distance, leaving the blast unimpeded. Friction primers for cannon have generally superseded the use of this lock, though it still maintains its place in the United States navy.

The elements of all gun-locks of the modern pattern, which have no breech-loading or revolving machinery to operate, are essentially as follows. The illustration shows that employed in the United States muzzle-loading small-arms.

Fig. 2343.

a, *hammer* or *cock*.
b, *tumbler*.
c, *bridle*.
d, *bridle-screw*.
e, *sear*.
f, *sear-screw*.



Gun-Lock.

g, *sear-spring*.
h, *sear-spring screw*.
i, *mainspring*.
k, *swivel*.
l l, *side screws*.

The hammer fits on the *square* of the *tumbler*, which it rotates when drawn back, so as to allow the *nose* of the sear to fall into notches of the tumbler when at half-cock and at cock. Both the sear and tumbler are held in place by the *bridle*, which confines them to the lock-plate. The trigger, when pressed, acts on the rear end of the sear, lifting the other end out of the cock-notch of the tumbler, which is then permitted to move by the action of the mainspring, carrying the hammer around with it.

Revolving, breech-loading, and repeating arms, having their firing mechanism necessarily operating in connection with those for loading and for withdrawing the cartridge-cases, require very different arrangements from those described, in many instances involving great multiplicity and complexity of parts. These will be found noticed under the head of FIRE-ARM, where a list of about 1000 occurs.

The lock of the needle-gun is the widest departure from the well-remembered form, the striker being a pointed rod which explodes the fulminate, either in the base of the ball, as in the Prussian gun, or in the base of the capsule, as in the American form of rifles. The percussion powder may be in a cap placed on a nipple on the side of the barrel; in a cap over a nipple on the cartridge; a pellet on an anvil at the base of the cartridge; a pellet or ring in a basin or in the flange of the cartridge; a pellet in the base of the bullet.

By position it may be *rear*-fire, *front*-fire, *side*-fire, *center*-fire. See CARTRIDGE; FIRE-ARM.

Gun-lock Ham'mer. The cock or striker of a fire-arm lock. See GUN-LOCK.

Gun-met'al. A bronze from which cannon may be cast. Ordinarily 9 parts copper and 1 tin. Other metals have been sometimes added or substituted for the tin, copper still remaining the basis of the alloy.

A few examples are given.

	Copper.	Tin.	Zinc.	Iron.

See ALLOY.

The Rosthorn (Austrian) alloys are known as "sterro-metal." One variety is soft, ductile, and capable of being worked into sheets or wire. The other is hard, and is represented as suitable for ordnance. From experiments made at the Imperial arsenal at Vienna, its tensile strength was, after single fusion, 28 tons to the square inch; after forging at a red heat, 32 tons; drawn cold and reduced from 100 to 77 sectional area, 37 tons. The metal thus tested contained a rather less proportion of tin and iron than is indicated above. Its specific gravity was 8.37. It is represented as possessing unusual elasticity. Field-guns of from 4 to 12 pounder caliber were worked out of single pieces under the hydraulic press, without impairing its tensile strength.

M. Sorel's alloy, composed of 8 copper, 1 zinc, and 1 tin, is said to resemble zinc in appearance, to be equal to copper and iron in hardness, more tenacious than soft cast-iron, readily turned, filed, and delivered from the mold in casting, and to endure exposure to moisture without tarnishing. It is susceptible of being bronzed, and is adapted for statues or exposed ornamental objects.

Gun'ner's Cal'i-pers. An instrument made of sheet-brass with steel points. The graduations show the diameters of shot and shell, the calibers of guns, linear inches, degrees of the circle, etc.

Gun'ner's Hav'er-sack. A leathern bag worn by a gunner for containing the smaller implements required in the discharge of his duty.

Gun'ner's Lev'el. An instrument for ascertaining the highest points at the breech and muzzle of a piece of ordnance, when on uneven ground, in order to determine the true line of sight.

It consists (*a*, Fig. 2344) of a spirit-level mounted on a frame having two branches with rounded ends,

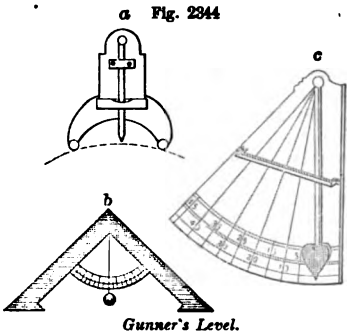

Fig. 2344

Gunner's Level.

and an upright piece with a perpendicular slider. The instrument is placed transversely on the upper part of the gun, say at the base ring, and moved to the right or left until the bubble of the level is central, the point of the slider then indicates the highest point of the piece at that part; repeating the operation at the muzzle gives another point in the line of sight, along which the gunner must aim to hit the object. These points are then marked on the metal.

Called also gunner's perpendicular.

b and *c* represent forms of what are called gunner's levels in the British service. Each of these is designed to be applied longitudinally to the gun to give it the proper elevation, the degree of which is ascertained by the graduated quadrant and plumb-bob.

Gun'ner's Per'pen-dic'u-lar. Another name of the gunner's level. It is made of sheet-brass, the lower part being cut out in crescent shape. It has a perpendicular slider, pointed at the lower end, and is used for finding the line of sight of siege-guns and mortars. See GUNNER'S LEVEL.

Gun'ner's Quad'rant. The gunner's quadrant is a graduated arc of 90°, or rather more, made of brass or wood, and having an arm attached which is passed into the bore of the gun for the purpose of ascertaining the elevation. The wooden level has a leaden bullet suspended by a string, which indicates the perpendicular, the deviation from which is measured on the arc. The metallic quadrant is of more elaborate construction, and has a spirit-level attached. See GUNNER'S LEVEL.

Gun'nie. (*Mining.*) *a*. A large, open, excavated space in a mine.

b. In Cornish, a term applied to breadth or width; *single* gunnies are three feet wide.

Gun'ny. (*Fabric.*) A heavy coarse goods used for wrapping bales of cotton, for cotton bags, etc. Made of jute, manilla, or hemp. A heavier grade than *burlaps*. Gunny is a Hindoo word, and the real article is made from fibers of the *cochorus* (jute); the bag made thereof is used to carry grain, etc., on the backs of buffaloes, and for enclosing articles for exportation, — rice, saltpeter, pepper, coffee.

Gun-pend'u-lum. 1. A pendulous box with sand-bags to receive the impact of a ball fired from a gun or cannon, and used to determine the strength of powder. See BALLISTIC PENDULUM.

2. A gun suspended from trunnions to measure by recoil the power of the powder of the exploded charge. See also ÉPROUVETTE.

A substitute means is a measurer of the rate of motion of the projectile, which forms one factor in the calculation for the power of the powder. See CHRONOSCOPE.

Gun'pow-der. A composition of niter, charcoal, and sulphur. The proportions in which these ingredients are mixed vary slightly, according to the place of manufacture or the destined use of the article. By the atomic theory there should be in 100 parts, 74.64 niter, 13.51 charcoal, 11.85 sulphur. In practice there are employed, —

	Niter.	Charcoal.	Sulphur.

Although the use of gunpowder in Europe can be traced back only to the middle or earlier part of the fourteenth century, yet it seems fully proved from various passages in ancient authors that it is one of those inventions whose origin is lost in the obscurity of a very remote antiquity. The fact appears indisputable that it originated in Central or Eastern Asia, where it was used for many ages previous to its introduction into Europe, where it appears to have been first made known by the Saracens.

Digitized by Google

In a code of Gentoo laws occurs a prohibition against the use by the ruler of "deceitful machines, poisoned weapons, and weapons of fire." To this document is assigned the date 1500 B. C. When Ghengis Khan invaded China, A. D. 1219, he carried with him *ho-pao*, or fire-tubes, which killed men and set fire to buildings.

Passages in Quintius Curtius and Philostratus indicate that Alexander was met in India by a people who used against him "storms of lightning and thunderbolts."

There are many scattered passages in the old writers, and many facts, quoted by Dutens, Sir George Staunton, Halhed, Hallam, M. Langles, Muratori, Reinaud, and Grove, which indicate the very early use of gunpowder.

It must be recollected that in many parts of Asia saltpeter occurs as an efflorescence on the surface of the ground, and its sputtering effects upon ignited charcoal, when a fire was built upon it, must have been very commonly observed. Sulphur is useful in the combination, but not essential for some purposes to which the explosive compound is applied.

In early ages, probably as early as the time of the exodus of the Israelites from Egypt, fire-works were common in China, and from thence, at a very remote period, they spread to India, where they were used on a scale which made them dangerous weapons when Alexander invaded that country, 327 B. C. There is no reasonable doubt that, long before they were employed as weapons, rockets and other pyrotechnic devices were used among these Eastern Asiatic nations, especially among the Chinese, with whom they have for many centuries formed an important item in public celebrations and festivals. From those devices, in which a charged paper tube expels fire-balls or pellets of explosive material, the transition is very easy to larger tubes with projectiles, which depend for execution upon percussive force. Such were the original fire-arms, and the strengthened paper tube or the bamboo was the first barrel.

We have occasion to notice, in the course of this work, that many arts in which the Chinese excelled were carried to India, and were cultivated in that congenial soil, until an irruption of another nation scattered the artificers or scholars, and gave to the world the secret or the industry which was locked up, as it were, within circumscribed limits. This has commonly occurred in the history of the industrial arts.

War quickened the extension of printing. In 1482 the storming of Mentz dispersed the workmen, and gave the art of printing to the world.

In 1146 Roger of Sicily plundered Greece, and took home with him to Palermo silk-worms, workmen, and the art of weaving silk. From Sicily it spread to France, Italy, and Spain, and from Italy to England.

Other instances might be cited where the irruptions of tribes or nations, or internecine disturbances, have disseminated arts, but the one most to our purpose is the invasion of India by Mahmoud of Ghizni, A. D. 1004, which seems to have been the means of diffusing the knowledge of gunpowder, the mariner's compass, and the art of glazing pottery and earthenware. The Saracens were the means of publishing the knowledge thus dispersed, and we regard it as certain that they introduced the knowledge of gunpowder into Europe.

The art of making felted fabrics was reintroduced into Europe by the Tartar hordes who took Thrace and Adrianople in 1361, and under Bajazet overran the provinces of the Eastern Empire before the end of that century.

The arts of making silk and other fine goods, crystal glasses, and jewelry, were carried to the Netherlands and to England by the Revocation of the Edict of Nantes, granted by Henry IV. in 1598, confirmed by Louis XI. in 1610, and Louis XIV. in 1652, and revoked by Louis XIV., Oct. 22, 1685. Fifty thousand Protestant families left France for more tolerant countries, and the world is the better off from the diffusion of their skill.

The more closely we examine the record, the more do we discover our indebtedness to the East; and the extreme East seems to have been the primary fountain of our industrial civilization.

The use of an explosive compound, *pulvis nitratus*, is mentioned in an Arabic writing in the Escurial collection, dating about 1249. The Moors used it in Spain in 1312, and in 1331 the king of Granada battered Alicant with iron bullets, discharged by fire from machines. In 1342-43, the Moorish garrison of Algesiras defended themselves against Alonzo XI., king of Castile, by projectiles fired from cannon by powder.

The Venetians used gunpowder in their wars with the Genoese in 1380. Gunpowder is mentioned in the French national accounts, 1338, and is said to have been used at Cressy, 1346, and to have contributed much to the success of the English.

The two Europeans whose names have been prominently brought forward as inventors of gunpowder.are Roger Bacon and Michael Schwartz.

Roger Bacon, in 1216, wrote a work entitled "The Secrets of Art and Nature," wherein he states that "from saltpeter and other ingredients we are able to make a fire that shall burn at what distance we please; and that sounds and coruscations resembling thunder and lightning might be formed in the air, much more to be dreaded than those that happen naturally, inasmuch as by its power armies and cities might be destroyed." Bacon did not claim the discovery, and had probably read the "Liber Ignium" of Marcus Græcus, written about A. D. 825, in which he describes the nature of the composition for making rockets. His formula is stated by one authority to have been, — sulphur, 1; charcoal, 2; saltpeter, 6. It is now difficult to sift the error from the truth, but it is said that in the recipe of Bacon the ingredients saltpeter and sulphur were given, and that the charcoal was stated anagrammatically, by the transposition of the letters of the words, *carbonum pulvere;* which he wrote "Lura nope cum ubre." This looks as though he considered it a secret; not necessarily his invention, but a dangerous compound not adapted for the use of the vulgar.

Michael Schwartz, a Cordelier monk. of Goslar, in Germany, about A. D. 1320, seems to have combined the three ingredients, and has been credited with the discovery. A commemorative statue of Schwartz was erected in 1853, at Freiburg.

Artillery was known in France in 1345.

In 1356, the city of Nuremberg purchased gunpowder and cannon.

The same year Louvain employed thirty cannon at the battle of Santfliet against the Flemings.

In 1361, a fire broke out at Lubec from the careless use of gunpowder.

In 1363, the Hanse towns used gunpowder in a conflict with the Danes.

It is commonly stated that gunpowder was first made in England, at periods varying from 1411 to 1438; but recent research by Rev. Joseph Hunter has brought to light records of its manufacture for the uses of the English army before it landed at La Hague, and previous to the battle of Cressy.

Digitized by Google

The ingredients for the manufacture of gunpowder should be of the greatest possible purity. The crude saltpeter is refined by washing, and then dissolving in the least possible proportion of hot water, and clarified by adding a very small quantity of glue, and boiling until the impurities, such as chloride of sodium, are deposited and the liquid becomes perfectly clear. It is then drawn off into pans, where it is cooled and crystallized in very minute grains, and afterwards washed with cold water, dried, and sieved. It should not contain more than $\frac{1}{3000}$ part of chlorides. That used in the best powder does not contain more than $\frac{1}{1000}$, and for the best sporting powder it undergoes a second refining, and contains not more than $\frac{1}{6000}$ part.

The charcoal has a great effect upon the quality of the powder. It should be light, friable, and porous, burning freely, and leaving little ashes. The woods used are willow and black-alder, principally the former. Branches not exceeding ½ inch diameter are selected, barked, and dried, after which they are charred in upright cast-iron cylinders, heated from the outside; about 65 per cent of the weight is found to pass off in the gaseous products distilled from the wood, leaving only 35 per cent of coal. It should only be prepared as required for use, owing to its liability to absorb moisture, and to spontaneous combustion when stored in quantities exceeding 30 pounds' weight.

Sulphur is refined by sublimation, the chamber in which the vapors condense being kept at a temperature of about 248° F., so as to allow the sulphur to be drawn off in liquid form. If much lower than this it condenses in the form of a powder, called flowers of sulphur, which always contains a proportion of sulphurous and sulphuric acids.

The three ingredients are now incorporated.

Dr. Scoffern's description of the process as conducted at the National Mills at Waltham, England, which produce powder of unsurpassed quality, gives a good general idea of the mode of manufacture.

It may be remarked that the process commonly employed in this country, though almost identical, differs somewhat in the preliminaries. Here the saltpeter is usually found sufficiently pulverized as it comes from the refinery. The charcoal is pulverized by being placed in a large cast-iron barrel, having ledges on its interior, with twice its weight of bronze balls, and the barrel is caused to rotate at the rate of from 20 to 25 revolutions per minute for two or three hours. The sulphur is similarly treated in barrels made of thick leather stretched over a wooden frame, and revolved from four to eight hours. The ingredients are incorporated by placing the charcoal and sulphur together in a rolling barrel, similar to that in which the sulphur is pulverized, and rolling them for one hour. The saltpeter is then added and rolled for three hours longer, after which the mixture is transferred to the cylinder or rolling mill, which consists of two cast-iron cylinders rolling in a circular trough with a cast-iron bottom.

At Waltham, the saltpeter, brimstone, and charcoal are ground separately in mills, each consisting of a pair of heavy circular stones slowly revolving on a stone bed. Next the ingredients are conveyed to the *mixing-house*. Here, in bins, are the saltpeter, brimstone, and charcoal, weighed in the exact proportions: saltpeter, 75; brimstone, 10; and charcoal, 15; in every 100 parts. Of the three ingredients, forty-two pounds are placed in a hollow drum, which revolves rapidly, and contains a fly-pan, which rotates in an opposite direction; in about five minutes a complete mixture is effected, and the charge is received in a bag tied over the lower orifice of the drum.

The *composition* is next taken to the *incorporating-mills*, and is now a *combustible* compound, which will acquire an *explosive* power by the thorough incorporation of ingredients. The mill consists of a pair of circular stones (*runners*) weighing about 3½ tons each, and slowly rolling over the powder, which is placed on the stone bed of the mill, surrounded by a huge wooden basin. The powder is previously damped, as it could not be safely ground dry; about seven pints of water (*liquor*) being added to the charge of forty-two pounds of powder during three and a half hours, the time of grinding. To insure this with precision, and to obviate the chance of any irregularity in a clock, the water-wheel which works two of these mills in one house also marks its revolutions on a dial, so that the attendant can never be mistaken in the time the charge has been "on," — a most important point, where the over-grinding of the too dry powder might cause it to explode. Sometimes a portion of the wood-work of the roof, or mill, becoming detached — such as a cog of the wheel — and falling into the pan, acts to cause a mass of powder to explode. As a protection, over each house containing a pair of mills is suspended a flat board, which, in case of an explosion, is first blown upward, and, being connected by wires to a cistern of water over the pan of the fellow mill, upsets the same, and drowns the gunpowder. The attendants are as little as possible in these mills, and only work by daylight. More hazardous processes, however, follow. The powder thus incorporated is in hard, flat lumps, and has again to be reduced to dust in the *breaking-down house*, by conveying it down an inclined plane, through rollers, which crush nearly 500 pounds in the hour. The powder is then taken to the *press-house*, and there, between gun-metal plates, is pressed in thin cakes to one third its bulk by a power of 700 tons in an hydraulic press. The cakes are roughly broken up, and sent in baskets to the *granulating-mill*, where the powder is again broken down into grains, the size being regulated by sieves. The floor is covered with hides fastened down with copper nails, and the mill can be started or stopped by a rope passing through the wall, which is bomb-proof. The powder is then dried, by heat, in the *stoving-room*, which is flanked externally by *traverses* (mounds of earth thirty feet thick), to confine explosion, should it happen, as much as possible to one house. Lastly, the powder is sifted in the *dusting-house*, where the sieves revolve with great velocity; the dust escapes through the meshes, and the gunpowder is drawn off through a sort of tap, into barrels, for packing. The finest powder is *glazed* by black-lead being shaken up with it; but cannon powder has not this finish.

The size of grain of gunpowder is varied according to its intended use. The finest is known as *sporting*, the next *rifle*, then *musket*, and lastly *cannon* powder. The rapidity of burning is in inverse proportion to the size of the grain. For very heavy ordnance a much larger grained powder than either of the above, called *mammoth* powder, was introduced by the late General T. J. Rodman. He also proposed the use of a powder composed of small uniform cakes with cylindrical perforations. This has since, under the name of *prismatic* powder by the Germans and Russians, and *pebble* powder by the English, been received with considerable favor.

The use of sawdust, resin, bran, sand, ashes, wood shavings, is as old as the writings of Siemienowicz,

Digitized by Google

1651. He remarked, very truly, that they have the effect of making the powder burn more slowly. The practice has been again and again introduced, in Brazil about 1800; by Thurnagel in Germany; Thomassin and Leblanc in France; Firzoo in Russia.

Dr. Gale has shown that by the addition of sand in certain proportions the powder is rendered non-explosive.

The white gunpowder invented by Captain Schultze, of the Prussian army, is prepared by sawing suitable kinds of wood into thin slices transversely of the grain. These are then, by means of a manifold punch, cut into grains of a definite size and shape, which are chemically washed to remove calcareous and other non-woody matters, and then treated with a mixture of nitric and sulphuric acids, washed with a solution of carbonate of soda and dried. In this condition the powder is stored away until it is wanted for shipment. It may be considered as a dense form of pyroxyline. The explosive quality is imparted by steeping in a solution of some one of the nitrates, ordinarily that of potash (saltpeter), but for some purposes the inventor prefers nitrate of baryta.

Another recipe for white gunpowder consists of equal parts of chlorate of potash, white sugar, and ferro-cyanide of potassium. Mix very cautiously, as it explodes by percussion. It is exploded by a red-hot body or a drop of sulphuric acid.

The following table shows the first recorded use in making gunpowder of the ingredients stated.

Charcoal, sulphur, and nitrate of potassa	*Time immemorial.*	Aloes	1869
Bituminous coal	1838	Fats and oils	1871
Bark (morus)	1855	Lime	1861
Peat	1856	Phosphorus	1864
Cork (burned)	1856	Bisulphide carbon	1863
Lycopodium	1856	Ferro-cyan. of potassa	1850
Horse-dung	1856	Chlorate of potassa	1850
Sawdust	1856	Carbonate of potassa	1859
Sugar	1856	Bichromate of potassa	1864
Tan	1853	Carbazotate of potassa	1838
Starch	1858	Azotate of potassa	1868
Flour	1858	Chloride of sodium	1856
Bran	1858	Nitrate of sodium	1857
Gum	1859	Sulphate of sodium	1862
Cannel coal	1861	Potasso-tartrate of sodium	1864
Caoutchouc	1863	Barilla	1864
Dextrine	1864	Carbonate of sodium	1864
Petroleum products	1864	Chlorate of lead	1862
Lamp-black	1865	Red sulphate of arsenic	1850
Cutch and gambier	1866	Sulphate of magnesia	1862
Grahamite	1869	Nitrate of strontian	1862
Paraffine	1869	Nitrate of baryta	1862
Logwood	1869	Nitrate of lead	1864
Carbolic acid	1869	Nitrate of iron	1869
Tannin	1869	Binoxide of manganese	1864
		Cyanuret of zinc	1864

Gun'pow-der-en'gine. A form of gas-engine in which the motion of the piston is caused by the evolution of gas resulting from the combustion of gunpowder. D'Hautefeuille worked upon this problem, using the gas to obtain a partial vacuum in a chamber; the exploding of the gas expelled the atmospheric air, and the gases suddenly condensing left the vessel nearly void.

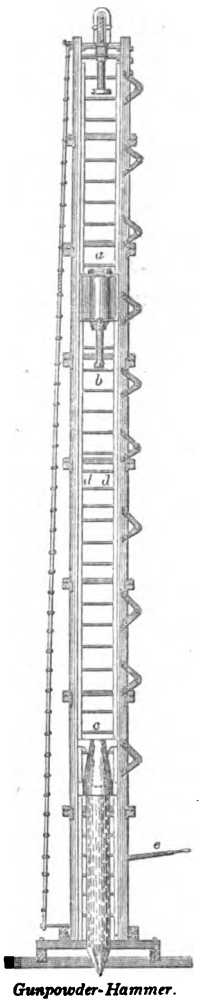
Huyghens adopted the same principle, but used a cylinder for his explosive chamber, the vacuum being utilized by the resulting atmospheric pressure upon the piston moving in the cylinder. Papin substituted a bell-valve over a hole in the middle of the piston for the leather tubes used by Huyghens.

In 1791, Barker patented a gas-engine having the main features of the modern gas-engine; streams of carbureted hydrogen gas and atmospheric air being introduced through different conductors into a cylinder, in which the gas was exploded, the effect being to drive a piston. See GAS-ENGINE.

Papin's apparatus consisted of a tube closed at bottom and having a valved piston below which a charge of gunpowder was exploded. The idea was, that the sudden blast of the explosion would expel the air, causing a vacuum and allowing the full atmospheric pressure to operate on the downward stroke. This was, however, not realized in practice, the pressure actually not being found to exceed half that of the atmosphere, owing to the non-production of a perfect vacuum by this means.

Gun'pow-der-ham'mer. A pile-driver operated by the explosive force of gunpowder. The hammer *a* is, as usual, arranged to slide in guides in a vertical frame. It is bored out cylindrically in the upper central part, and has a plunger *b* below. The pile-cap *c* has a cylindrical hollow in its upper part for the reception of this piston and a cartridge, and a conical seat below to fit the head of the pile. It is also fitted to the guides *d d*. The lever *e* is connected by a rope with a trigger at the upper part of the frame, by which the hammer is held in an elevated position. A cartridge is placed in the pile-cap *c*, and the piston allowed to drop, compressing the air contained in the cap *c* sufficiently to ignite a cartridge placed therein. The explosion throws up the hammer, which again drops by its gravity, and so on. The powder used is composed of 1½ parts chlorate of potash and 1 bituminous coal, finely pulverized and intimately mixed. The charge is very small, one third of an ounce sufficing to operate a hammer of 675 pounds' weight. The piston, at the upper part of the machine, enters into the cavity in *a* and acts as a buffer, preventing injury to the machine and assisting the downward movement of the hammer.

Fig. 2345.



Gunpowder-Hammer.

Gun'pow-der-mill. Fig. 2346 shows an arrangement by which several gunpowder rolling-mills are driven from a water-wheel *a* by bevel and spur-gears *b b e e*. The cast-iron or stone rolling-cylinders

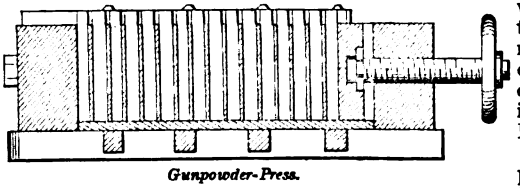
c c revolve on a horizontal axis which is carried around by a vertical shaft within the circular trough *d*, into which a charge, usually 75 or 150 pounds, of the incorporated materials from the rolling barrel has been placed. The rollers are set in motion, slowly at first, and afterwards more rapidly, and kept going three hours for a charge of 150 pounds, or for a less quantity a proportionately less time, a little water being added to prevent danger of explosion should the materials become too dry. A scraper follows each roller to keep the composition exposed to the action of the rollers. At the end of this time the mass has become thoroughly incorporated, is of a brownish red color, and is termed *mill-cake*. See GUNPOWDER.

Gun'pow-der-press. For pressing *mill-cake* into hard cake preparatory to granulating. That illustrated is particularly designed for compressing

Fig. 2347.



Gunpowder-Press.

dust-powder into hard cakes between upright plates which are adjustably arranged in the box by means of a gage-bar. The pressure is applied by a follower operated by a horizontal screw.

Gun-room. (*Nautical.*) The purpose of this room, at the after end of the lower gun-deck, differs according to the rate of the vessel and also in different services.

In war vessels of moderate size it is occupied by the lieutenants and some other officers. In vessels of larger size the lieutenants occupy the *ward*-room, and the junior officers the gun-room.

Gun-search'er. An instrument with several projecting prongs to ascertain whether the bore of a gun be honeycombed.

Gun-stock. The part of a gun to which the barrel and lock are fastened. It is usually of walnut; in Europe the *Juglans regia*, in America the *Juglans nigra*.

Gun-stocks, until the invention of the Blanchard lathe, were made by hand in a laborious and tedious manner. This machine was introduced into the Springfield Armory about 1820.

A rough chunk of wood is placed in the first of the stocking machines, from whence it emerges with its sides cut to the proper shape for turning. In another machine its butt-end is sawed, and a diagonal line cut at the breech. The third, armed with two circular saws, fashions the upper part of the stock in its finished form. Another machine reduces the butt to its ultimate shape. Another simply planes various places in the sides of the stock as points for the working of yet other machines, — an operation which is known as *spotting*. A sixth machine performs six distinct items, called *grooving* for the barrel, breech-pin, and tang; *heading* down, *milling*, and *finish-grooving*. The stock is at this stage prepared for the *fitting* in of the barrel. A seventh machine planes the top, bottom, and sides, while the eighth and ninth do the *shaping* and *bedding* for the butt-plates. The next machine prepares the stock for the reception of the lock. Another machine is used to cut for the guards, to bore for the side screws of the lock, and two more to make places for tips and bands. After these various operations comes the second turning and smoothing of the work; then the grooving for the ramrod; then the boring for the ramrod from the point at which the groove ends. These machines are each provided with a pattern or templet, which is the exact counterpart of the cavity or other form to be produced in the stock. They are furnished also with cutters or borers, which, being placed above the stock, are made to revolve rapidly and cut the wood in exact imitation of the pattern below. The movements of the tool are controlled by a guide which is inserted within the pattern. The tool is made to revolve by means of small machinery within its frame, the latter and all within it moving together with both lateral and vertical motions, being governed by the guide, which is connected with it, by the aid of very curious and intricate machinery.

The work of the artisan, when the machine is in motion and the stock is adjusted in its bed within it, beneath the borers or cutters, is simply to bring the guide down into the pattern, and move it about the circumference and through its center. The cutting-tool follows the movements of the guide, and the result is a perfect duplicate in the stock of the form in the mold below. See LATHE FOR TURNING IRREGULAR FORMS.

Gun-tack'le. (*Nautical.*) The ropes and pulleys attached to the sides of the ports and to the gun-carriage by which the gun is run out. It consists of two single blocks, one movable and the other fixed, the standing end of the fall being secured to the movable block.

Gun'ter's Chain. A surveyor's chain 66 feet or 4 rods (of 5½ yards each) in length, having 100 links, each joined to the adjacent one by three links. A square chain is $\frac{1}{10}$ of an acre, or 10,000 square links.

It was invented by the Rev. Mr. Gunter (1581–1626), of England, to aid in calculating areas.

Gunter's Chain.

7.92 inches = 1 link.
100 links = 1 chain, 4 rods, or 22 yards.
80 chains = 1 mile.

Gun'ter's Scale. A large plane scale invented by Mr. Gunter of England. It has various lines of numbers engraved on it, by which questions in calculation, navigation, and surveying are solved mechanically by the aid of the dividers or a slider.

On one side of it are scales of equal parts, chords, sines, tangents, rhombs, etc.; on the other side are the corresponding logarithmic lines.

It consists of a flat ruler of boxwood, two feet long, having various lines laid down upon it, by means of which various problems may be performed by the extension of the compasses only. This will be best explained by a description of the line called the *line of number*, or Gunter's line, which is adapted to the solution of arithmetical questions, and exhibiting a few practical examples.

The *line of numbers* is the logarithmic scale of proportionals, which, being graduated upon the ruler, serves to solve problems in the same manner as logarithms do arithmetically. It is usually divided into 100 parts, every tenth of which is numbered, beginning with 1 and ending with 10, so that if the first great division stand for the $\frac{1}{10}$ of an integer, the next great division will stand for $\frac{2}{10}$, and the intermediate divisions will represent 100ths of an integer, whilst the large divisions beyond 10 will represent units; and if the first set of large divisions represent units, the subdivisions will represent 10ths, whilst the second set of large divisions will represent tens, and the subdivisions units, etc.

Digitized by Google

The general rule for using this instrument is as follows: Since all questions are reducible to proportions, if the compass be extended from the 1st term to the 3d, the same extent will reach from the 2d to the 4th term.

The following are a few examples of some of the uses of this line:—

1. To find the product of any two numbers, as 4 and 8: extend the compass from 1 to the multiplier 4, and the same extent applied the same way from 8 the multiplicand will reach the product 32.

2. To divide one number by another, as 36 by 4: extend the compass from 4 to 1, and the same extent will reach from 9 to 36.

3. To find a fourth proportional to three given numbers, as 6, 8, and 9: extend the compasses from 6 to 8, and this extent laid the same way will reach to 12, the fourth proportional required.

4. To extract the square root of a number, say 25: bisect the distance between 1 on the scale and the point representing 25; then half this set off from 1 will give the point 5, which is the root required.

In the same manner the cube-root or the root of any higher power may be found by dividing the distance on the line between 1 and the given number into as many equal parts as the index of the power expresses, then one of those parts set from 1 will extend to the number representing the root required.

An improvement which has rendered the compasses unnecessary consists in having two lines of numbers placed one over the other, one of which lines is engraved upon a slider moving in a groove and is applied as follows:—

The 1st term of the proportional upon the slider being set against the 3d term on the fixed scale, the 2d term upon the slider will stand opposite the 4th term upon the fixed scale.

Instruments of this description with scales suited to almost every branch of art in which calculation is required are now common among intelligent workmen, and the scale of chemical equivalents by which the labors of the chemist are so much facilitated is constructed upon the same principle.

Gun'wale. The upper planking covering the timber-heads round the ship.

A piece of timber around the top side of a boat, and having rowlocks for the oars.

Gur-glet. A porous earthen jar for cooling water. See ICE-MAKING MACHINE.

Gur'let. (*Masonry, etc.*) A pickaxe with one sharp point and one cutting-edge.

Gur'nie. (*Mining.*) A level or working. See GUNNIE.

Gus'set. 1. An angle-iron or bracket stiffening the angle of a structure.

2. An angular piece of iron inserted in a boiler, tank, etc., where it changes from a cylindrical to a square form, etc., as in the junction of the barrel and fire-box of a locomotive.

Gut. 1. Prepared sheep's entrails. See CATGUT.

2. The sac of silk taken from the silk-worm and stretched into a line for a snood.

Gut'ta. One of the ornaments resembling drops, placed in the epistylium of the Doric order below the triglyphs.

Gut'ta-per'cha. The hardened juice derived from the Isonandra, gutta-tree. It is said to take its name from the Malay words *gutta*, gum, and *percha*, the particular kind of tree which yields the juice. The tree is indigenous to the islands of the Indian Archipelago, and particularly to the Malayan peninsula, whose inhabitants have long used the gum for spear handles and other objects, formerly cutting down the tree for this purpose, but now, instructed as to its commercial value, collecting the juice in bowls or cocoa-nut shells from incisions made in the tree. It very soon hardens, and is ready for manufacture. It was first made known by Dr. Montgomery, in 1843; about the same time some was brought to London by Dr. D'Almeida. The former gentleman was rewarded by the London Society of Arts with a gold medal.

The juice consolidates in a few minutes after being drawn, and is then formed by the hand into oblong masses about seven inches long and six inches thick. These generally contain bits of wood and other impurities, which may be removed by immersion in boiling water until the mass is sufficiently softened to be rolled out into a thin sheet, when they may be picked out by hand. Its plasticity when heated allows it to be readily molded into various forms, such as vessels for holding liquids, etc., which are made and offered for sale by the natives.

It is completely unaffected by cold water, and is insoluble in boiling alcohol, but may be readily dissolved by boiling spirits of turpentine, also by coal-tar or naphtha. It resists alkalies and acids, being only affected by the nitric or sulphuric in a highly concentrated state, and is a non-conductor of heat and electricity.

Though applicable to many of the purposes for which india-rubber is employed, it differs greatly from that gum in many respects, being lighter, of finer grain, and very tough and unyielding. Its appearance in the crude state is also very different, the color being a grayish white.

The peculiar adaptability of gutta-percha to many kinds of surgical appliances, and to coating telegraph-cables, is well known.

The mode of manufacture is simple.

The first process consists in cutting the masses into thin slices by means of a vertical wheel whose face has fixed cutters.

These slices are then thrown into a steam-heated tank, by which they are softened, depositing the dirt and heavier impurities, after which the mass of gum in a pasty condition is transferred to another rotary machine provided with teeth, by which it is torn into fragments. These fall into a tank of water, on which they float, any remaining impurities falling to the bottom. The fragments are next softened to a dough-like consistency by immersion in hot water, and thoroughly kneaded by being placed in heated hollow cylinders, within which rotating drums mix the plastic mass and impart to it a uniform consistency. It is now ready for being drawn into sheets or tubes. In forming sheets the mass is passed between steel rollers at a distance apart corresponding to that of the sheet to be made; by this time it has cooled to a solid consistency, and may, by means of adjustable knives, be cut into strips of any desired width before leaving the machine. In making tubes, the gum while yet soft is placed in heated cylinders and forced through hollow molds in a manner similar to that used in making clay drain-pipes. For stamped articles the sheets are cut into appropriately sized pieces, which are heated and compressed between dies. In coating telegraph-wires several of the wires are laid parallel, a strip of gutta-percha is placed above and another below them, and the whole is passed between two polished grooved rollers. The pressure binds the two surfaces of the gutta-percha firmly together and to the wires, while the ridges between the grooves indent the gum so deeply that it may be easily separated longi-

tudinally, each strip containing its own core of copper.

Gut'ta-per'cha Plates. Forms for the ordinary printing-press taken with gutta-percha. An intaglio impression is taken from the form. This, when cold, forms a matrix for obtaining a cameo gutta-percha impression which is used in the press.

Gut'ter. 1. (*Hydraulic Engineering.*) The trench made to hold puddling on the side of a canal.

2. A channel or ditch alongside a traveled road or path to lead off surface water.

3. (*Architecture.*) A trough or channel collecting the water which runs from a roof and leading it to pipes in which it descends to the earth.

A (Fig. 2348) shows the usual arrangement of gutters in England, where parapets are generally carried up above the supporting wall.

This appears, and is said to be, very productive of leakage and injurious to the woodwork of the roof. The Greek or Gothic eave is much better; let the water go, and catch it afterwards if you want to.

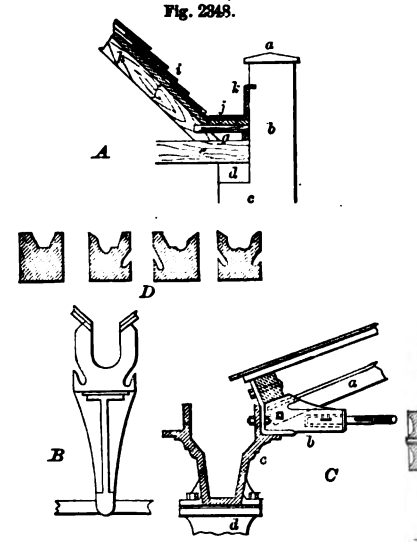
a, *coping*.
b, *parapet*, the outer edge *throated*.
c, *wall*.
d, *wall-plate*.
e, *joist*.
f, *rafter*.
g, *gutter-board*.
h, *eave-board*.
i, *slates or shingles*.
j, *gutter*.
k, *flashing*.

B is the form of gutter, scored out of a solid piece of timber, which was used in the London Crystal Palace of 1861. It was supported on the upper flanges of the main trusses.

C is the arrangement adopted at the Smithfield Market, Manchester, England. The principal rafter *a* and tie *b* rest on the cast-iron gutter *c*, which is supported by the column *d*.

D exhibits several forms of top and side gutters worked out of the solid.

Fig. 2348.



Gutters.

4. (*Hydraulic Engineering.*) A device (*E*, Fig. 2348) for raising water by the vertical oscillation of a trough. As a crude and cheap device it is represented in the accompanying cut, which does not need lengthy description. As a more important machine it is shown under BAIL-SCOOP (which see). It is principally used for small lifts, but by a succession of lifts it may be useful for higher elevations.

The *jantu* of the Bengalese is a counter-weighted *gutter*.

A pendulous *gutter* with several steps of ascent for water is shown in Ewbank's hydraulics.

5. (*Printing.*) One of the *sticks* placed between the pages in a *form* to separate them to such a distance that when the sheet is printed and folded the margin shall be regular and uniform.

Gut'ter-ledge. (*Nautical.*) A bar laid across a hatchway to support the covers.

Gut'ter-snipe. (*Printing.*) A single slip-poster for attaching to curbstones.

Gut'ter-stick. (*Printing.*) One of the pieces of furniture which separate the pages in a form.

Guy. 1. A stay-rope passing from the top of a spar to a post or anchor in the ground, and used to steady it. As the *guys* of a *derrick* or *shears*. See DERRICK; SHEARS.

2. The stay-rod which connects the floor of a suspension bridge with the land on each side, in order to prevent swaying.

3. A rope to steady a body in hoisting.

4. A rope which trims and steadies a *lower studding-sail boom*. The *fore-guy* leads from the boom-end to the *spritsail-gaff*, thence to the heel of the bowsprit, and thence inboard; the *after-guy* leads from the boom-end to a sheave in the ship's side, and thence inboard.

5. A rope from the end of a jib-boom or flying jib-boom to the end of a *spritsail-yard* or *spritsail-gaff*, and thence to the ship's bow, to stay the spar laterally.

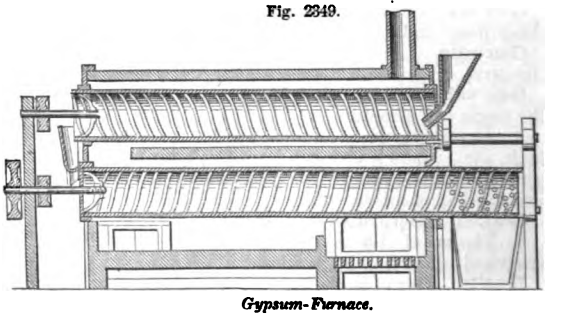
Gybe. (*Nautical.*) The shifting over of the boom of a fore-and-aft sail.

Gyle. 1. Fermented wort for making vinegar.

2. A large vat or cistern. The liquor gyle in a brewery is the water-cistern or vat. A *gyle-tun*.

Gyp'sum-fur'nace. A furnace in which natural gypsum, a hydrate of sulphate of lime, is calcined at a comparatively low heat — about 300 F. — in order to drive off the water of constitution. The process is called *boiling*, as the ebullition is very marked. In the illustration is shown a furnace containing

Fig. 2349.



Gypsum-Furnace.

two rotary boilers placed one over the other and provided with rotary conveyors. The gypsum is fed through the boilers consecutively, and is thence emptied upon a cooling surface and packed in barrels.

Gy'ro-scope. An instrument for illustrating the tendency of a revolving body to maintain its

Digitized by Google

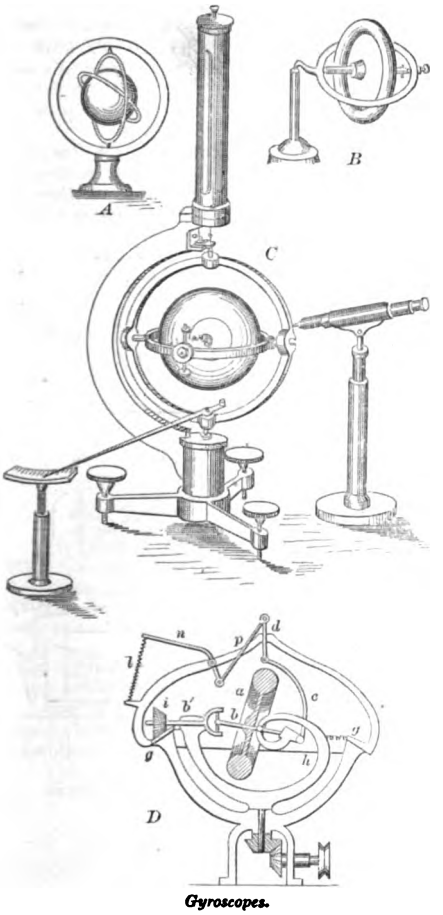
rotation in a fixed plane when free from the influence of disturbing forces.

It is susceptible of various forms. The earliest, probably, was that of Laplace, for illustrating the precession of the equinoxes.

The principle involved is that of Galileo's second law of motion, that a body actuated by several forces moves in the direction of their resultant.

Several centuries back the Italian academicians noticed the apparent displacement of the plane of vibration of the pendulum. Foucault (1852) first

Fig. 2350.



Gyroscopes.

connected this fact with the diurnal motion of the earth, which he illustrated by means of a pendulum (see PENDULUM) and a gyroscope contrived by him.

Bohnenberger's (1765–1831) apparatus (*A*, Fig. 2350) consists of a disk or sphere suspended in gimbals, which are mounted in a ring supported on a stand.

The interior ball and ring may be set at any angle with the outer one, and rotation imparted by a string, when it will be found strongly to resist any attempt to turn it from the plane of its rotation. This disposition of a rotating object to maintain its revolutions in one plane, designated as fixity or persistence of the plane of rotation, may be farther illustrated by the tendency of a trundling hoop or rotating top to remain upright, and by the directness of flight of rotating projectiles.

About 1832, Professor W. R. Johnston, of Philadelphia, devised an instrument which he termed a *roloscope*, for illustrating this principle. He also showed the effect of rotary motion in overcoming the force of terrestrial gravity by the device shown at *B*, Fig. 2350.

In this a disk is pivoted within a ring, its axis is extended and turned down, so that one end may be supported in a depression at the top of an upright standard. When the disk is placed vertically and rapid rotation imparted, it will maintain its rotation around the standard in a horizontal plane so long as its velocity is considerable, but when this ceases it falls.

C illustrates Foucault's gyroscope for demonstrating the rotary motion of the earth.

A carefully constructed disk is delicately suspended in gimbals within an outer ring vertically pivoted in a frame. The disk is brought into the plane of the meridian and rotated at a great velocity by machinery capable of instantaneous disconnection.

As the plane of the meridian at the moment of starting the apparatus coincided with some celestial meridian, the gyroscope will, while it maintains its rotation, keep in the plane of the latter, that is a fixed line in the heavens, while the terrestrial meridian is carried past it at the rate of 15° per hour. This is shown by a graduated horizontal arc affixed to the gyroscope, which is viewed through a telescope whose axis is fixed in the plane of the terrestrial meridian. It is obvious that were the earth a fixed body the axis of the telescope would always coincide with the same point on the arc, but the latter always maintaining the same vertical plane in space while the direction of the former is constantly changing with the diurnal revolution of the earth, the arc will appear to move in a direction contrary to the earth's rotation.

Gy'ro-scope-gov'ern-or. In Anderson's governor (*D*, Fig. 2350) the principle of the gyroscope has been adapted as the means of regulation.

a is a heavy wheel, the axle *b b'* of which is made in two pieces connected by a gimbal joint, the respective sections carrying the wheel *a* and pinion *i* respectively. The piece *b* is connected at its middle by a hinge joint with the revolving frame *h*, so that variations in the inclination of the wheel *a* will cause the outer end of the piece *b* to rise and fall. The frame *h* is driven by bevel gearing from the engine, and by that means the pinion *i* is carried round the stationary, toothed circle *g*, and the axis of the wheel *a* thus receives a rapid rotation. When the frame *h* and wheel *a* are in motion, the tendency of the wheel *a* is to assume a vertical position, but this tendency is opposed by a spring *l*. The greater the velocity of the governor, the stronger is the tendency above mentioned, and the more it overcomes the force of the spring, and *vice versa*. The piece *b* is connected with the valve-rod by rods *c d*, and the spring *l* is connected with the said rod by lever *n* and rod *p*.

Gyves. Shackles or fetters.

Digitized by Google

H.

Ha'beck. An instrument used in dressing cloth.

Hack. 1. A tool for cutting jags or channels in trees for the purpose of bleeding them. Pines are *hacked* for turpentine; maples *tapped* for *sap*, or *sugar-water* as Western farmers prefer to call it.

The turpentine hack is a tool with a curved or angular edge to cut channels through the bark and alburnum in an oblique direction, so as to lead the resin towards a *boxing* cut in the tree, or to a cup suspended to catch the drip.

2. A drying-frame for fish. A *flake*.

3. A *pile* of bricks arranged in regular order for *drying*, previous to building up in the *clamp* or *kiln* for *burning*.

4. Wooden bars in the tail-race of a mill.

5. A dung-fork.

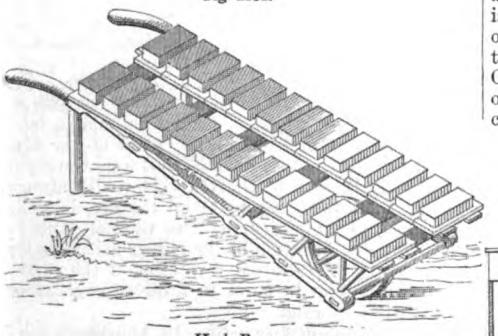
6. A large pick used by miners in breaking stone.

7. A carriage for hire (hackney-coach).

8. A feed-rack for cattle.

Hack-bar'row. A barrow on which bricks are conveyed from the molder's table to the drying-ground, where they are sun-dried or *hacked*, and

Fig. 2251.



Hack-Barrow.

temporarily covered with a thatching of straw to protect them from rain. Covered sheds are sometimes used.

Hack'but. (Ger. *hackbret*, a *hackboard*, or chopping-board.) An old name for the *dulcimer*. See PIANO-FORTE.

Hack'er. A cutting-tool for making an oblique incision in the pine-tree for leading the gum turpentine towards the *box* in which it is collected. A *hack*. The *round-shave* is used in chipping, and the *scraper* for removing the gum from the *box face*.

Hack'er-y. An East Indian two-wheeled cart, drawn by bullocks.

Hack'et. (*Joinery.*) A hatchet.

Hack-file. (*Locksmithing.*) A coarse slitting-file.

Hack-ham'mer. A hammer terminating at each end in an obtuse chisel-edge, kept in repair on the grindstone. It is used as the *peen* of an ordinary hammer, but is narrower, and therefore more local and energetic in its effects. The *hack-hammer* for reducing unequal protuberances on grindstones is shaped like an adze and has a short handle. When the grindstone has worn unequally, it becomes necessary to dress it, and the high places, being marked, are hacked by oblique and crossing checker lines, which cause it on the next grinding operation to wear more at those points and thus restore equality.

Hack'ing. 1. (*Masonry.*) The division of a portion of a course of stones into two of smaller hight when the larger stones do not hold out.

2. A process employed in dressing the faces of rough grindstones by the use of a hack-hammer, an implement resembling an adze. In some cases the faces of metallic or wooden polishing-wheels are similarly treated, a sharper implement being used.

3. Piling of molded bricks to dry. See HACK.

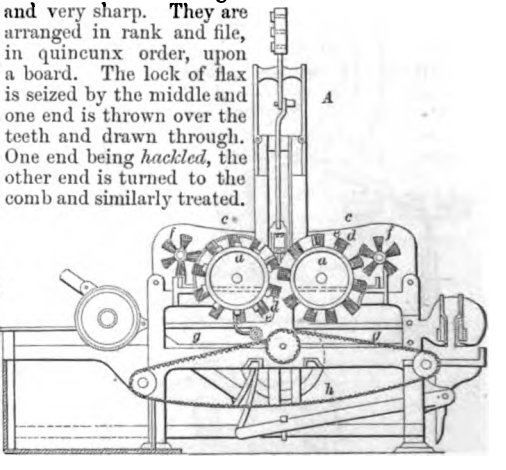
Hack'ing-out Knife. The glazier's knife for cutting out the old putty from the fillister of a sash, in reglazing.

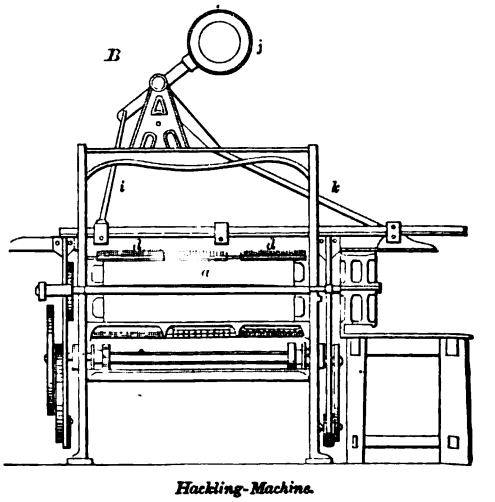
Hack-i'ron. (*Mining.*) A miner's pick. A *hack*.

Hack'le; Heck'le; Hatch'el. A board set with sharp steel spikes for combing or pulling out hemp or flax to dispose the fibers in parallelism, and to separate the *tow* and *hards* from the finer fiber.

The teeth are of steel from 1 to 2 inches in length and very sharp. They are arranged in rank and file, in quincunx order, upon a board. The lock of flax is seized by the middle and one end is thrown over the teeth and drawn through. One end being *hackled*, the other end is turned to the comb and similarly treated.

Fig. 2252.





Hackling-Machine.

Digitized by Google

This separates the ribbons of fiber, removes any remaining traces of the *boon* or cellular matter, and divides the fiber into two portions, the *short* and the *long*, the *tow* and the *line*.

The process is repeated on a fine hackle whose teeth are more numerous and thickly set. The produce is from 40 to 60 per cent of fine flax; *line*.

Hack'le-bar. One of the *gills* or spikes over which the lock of flax or hemp is thrown and drawn to lay the fibers parallel and comb out the refuse.

Hack'ling-ma-chine'. A machine for dressing flax.

Fig. 2352, *A* is a side and *B* an end elevation of a hackling-machine adapted for dressing short or cut flax. The two rollers *a a* are caused to rotate inwardly toward each other, and are fed with the raw material from a trough *c*. The peripheries of the cylinders are interspersed with alternate rigid hackles *d* and brushes *e*, so that they alternate on each. The exterior rotating cylinders *f* are also provided with brushes. The broken flax from an upper trough passes between the rollers and is deposited in the trough *g*. Refuse falls between the bars of a grate, and is removed by the endless carrier *h*. One of the cylinders *a* and the brushing cylinders *f* may have a longitudinal movement. On raising the receiving-trough, the rod *i* pushes up the weight *j*, which, by means of the connecting-rod *k*, causes the holder to traverse the width of one set of brushes.

Hack'ney-coach. (*Vehicle.*) An English term for a coach plying in the streets for hire. It has two facing seats inside.

Fig. 2353.

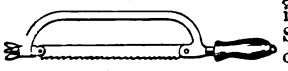
The First (English) Hackney-Coach.

They were introduced into France in 1650 (*fiacre*), and about the same time into England. They are mentioned by Pepys, 1660.

The name is French (*coche-à-haquenée*).

Hack-saw. A frame saw of moderate set, tolerably close teeth, and good temper; used in sawing metal. Such a saw is used to cut the nicks in heads of screws, in cutting off bolts, etc.

Fig. 2354.



Hack-Saw.

Hade. (*Mining.*) The *dip*, *inclination*, or *slope* of a vein or stratum. The angle it bears to the horizon. The *underlay*.

Had'ley's Quad'rant. (*Optics.*) An instrument for measuring altitudes. Used principally at sea. See QUADRANT; SEXTANT.

Hag'but. An old fire-arm with a stock bent down to form a ready means of grasping. An *arquebus*.

Hæm'a-dyn-a-mom'e-ter. An instrument for ascertaining the force of the circulation of the blood. *Hæmatometer; hæmatodynamometer.* See SPHYGMOMETER.

Haft. The handle of a tool or knife. Some handles have specific names, as *helve*, *nib*, etc. Some hafts are solid, others have a central plate and side pieces called *scales*; e. g. knife-handles.

Ha-ha. A fence or division wall so depressed below the ground surface as not to obstruct the view. A *sunk-fence*. A ditch with a *scarp*.

Hair. 1. A filament growing from the skin of an animal.

Curled hair for stuffing sofas, cushions, etc., is carded by hand-cards, which straighten, disentangle, and clean it; this is taken in bunches and spun into a rope, the next *top*, as the bunch is called, being interplaced with the loose strands of the former. The rope is wound on a wheel, and the coil steeped in water for three or four hours, and dried in a hot oven. The ropes are then untwisted, the hairs torn apart, and are ready to form stuffing.

Spun into smaller strands, hair is used for *nose-bags* of horses, bags for containing ground and heated flax-meal in the press, and also for containing prepared lard in the press from which lard-oil flows.

Curled-hair cords are also used for clothes-lines, and when fine also form fishing-lines.

Long and fine horse-hairs are used for the bows of violins and other instruments of this class. Also for making HAIR-CLOTH (which see).

The English lawyers affect horse-hair wigs, and horribly funny they look. Goat's hair is sometimes substituted for the true equine capillus, and this may partially account for their pugnacity and the fact that they are in bad odor with peaceable persons.

2. (*Fire-arms.*) The secondary spring device in one form of pistol and rifle lock, which is freed by the hair-trigger, and collides with the tumbler-catch to unlock the tumbler.

Hair-brush. A fine description of brushes of bristles assorted by color, strength, and quality, and put up in superior manner, hard, soft, or silky, according to purpose and taste. The better class are *trepanned*, a mode of secretly fastening the bunches without gluing a scale of veneer over the wires.

Hair-clip'ping Shears. A scissors for clipping the human hair, or one for clipping horses; the latter have sometimes a guide-bar, which forms a gage for length in cutting.

Hair-cloth. Cloth of goat's hair was used for covering the military engines of the Romans, as we read in Arrian, Thucydides, Ammianus, etc. Curtains of goat's hair were used in the Wilderness tabernacle of the Hebrews. The goat's hair cloth was called *shac* or *sac* in Hebrew, Chaldee, and Syriac; in the Septuagint it became *saccos*; in the Vulgate *saccus*. The Latin *sagum* and English *sack* perpetuate the sound and sense. (See SACK.) The nose-bags of the Arabian horses are of goat's hair cloth, and from them they eat their barley habitually. Goat's hair cloth also covers their tents. See also CAMLET.

Horse-hair for the manufacture of hair-cloth is principally derived from South America, and is imported in bales weighing about 1,000 pounds.

In the process of manufacture, it is first sorted according to color, and then hackled to get the hairs straight and remove dirt. A number of tufts are then placed between the teeth of two cards, and the longer hairs removed by hand, so as to leave only those of uniform length remaining. It is now ready to be woven or curled, according to quality. Hair is curled by forming it into a rope which is afterwards boiled, and then baked so as to set the kink in the hairs.

Hair-cloth is made from the longer and better varieties. The hair is first dyed, usually of a black color, and is merely employed as the weft of the cloth, the warp being composed of cotton or linen thread, according to quality and purpose. The process for-

Digitized by Google

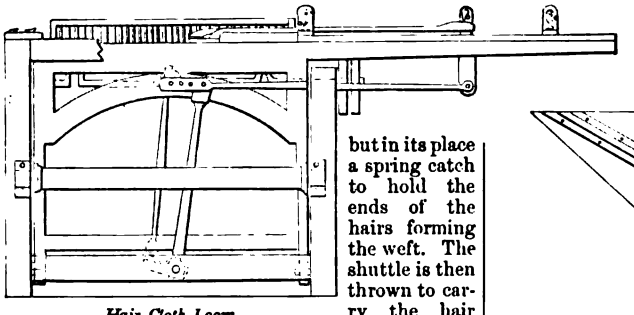
merly required two hands to each loom, but those at present used only require the attendance of one person, and recently power-looms have been employed.

After leaving the loom, the cloth is pressed between hot metallic plates to polish it.

Hair-cloth Loom. The *warp* of the web is of black linen yarn; the hair *weft* is thrown with a long hooked shuttle or a long rod having a catch hook at its end. The length of this boxwood shuttle is about 3 feet, its breadth ½ inch, and its thickness ⅛ inch. The *reed* is of polished steel. The weaver passes the shuttle through the *shuttle-way* when it is opened by the treadles; a child presents a hair to the catch of the shuttle, and the weaver draws it through the *shed* and beats it up by two motions of the *batten*. The hairs are laid in a trough of water to keep them supple. The warp is dressed with paste, and the hair-cloth web is hot-calendered to give it luster.

The shuttle for hair-cloth weaving has no pirn,

Fig. 2355.



Hair-Cloth Loom.

but in its place a spring catch to hold the ends of the hairs forming the weft. The shuttle is then thrown to carry the hair through the shed; at the other end of the shuttle-way the hairs are released by raising the catch.

In the illustration, the moving jaws of the nippers are raised by cams to allow the introduction of the hairs, and are opened by cams at different times to drop the hairs at different positions in the shed.

Hair-com'pass. A pair of dividers, one of the legs of which is provided with a set screw and spring, admitting of very nice adjustment.

Hair-cord. (*Fabric.*) A cotton goods, the warp of which consists of corded ribs.

Hair-di-vid'er. A dividing compass having one leg arranged for minute movements by a screw; used for fine adjustments.

Hair-line. 1. The fine line or up-stroke of a letter.

2. A kind of type having all fine face-lines.

3. A fishing-line of horse-hair.

Hair-pen'cil. A fine brush for painting. Small tufts of hair inserted into quills. The hairs of the camel, fitch, sable, badger, squirrel, martin, minever, European polecat, raccoon, goat, or other animal, are used for brushes of different qualities.

A small tuft of the hairs is collected with the points all in one direction, and the bunch is bound by a strong thread, and passed point first through a wet quill, so that the point projects to the required distance. The quill shrinks tightly upon the bunch in drying.

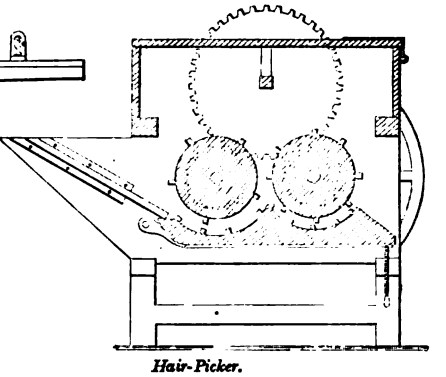
The various sizes require the quills of the crow, pigeon, goose, turkey, or swan. Larger bunches are secured in tin-plate tubes.

The ancient Greek painters used hair-pencils and palettes.

They are now principally used by artists in water-colors, and to some extent by house and sign painters in lettering, graining, and other fine work.

Hair-pick'er. A machine for cleansing and straightening hair. The one represented is for operating on loose hair. The two rollers have similar rotation by connection with a common motive wheel,

Fig. 2356.



Hair-Picker.

and turn in a double recessed, adjustable, concave block. The faces of the rollers and concave are armed with pins. The hair is straightened and dirt removed by being drawn through between the rollers and the concave surfaces.

Hair-pin. 1. A pin used in fastening up the hair. A *corking-pin.*

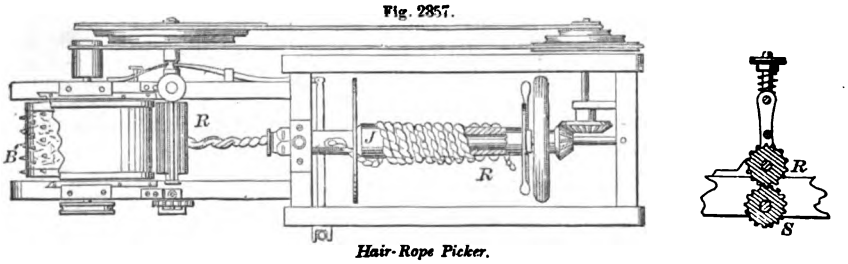
2. A forked pin commonly used by ladies in securing the braids or bands of hair.

Hair-py-ri'tes. (*Mining.*) A native sulphuret of nickel which occurs in capillary filaments of a yellow-gray color.

Hair-rope Pick'er. A machine for unwinding and picking to pieces hair-rope which has been twisted, wetted, and baked to give a permanent curl to the hair.

The rope is coiled around the shaft *J*, the revolution of which untwists it. It then passes between the fluted rolls *R S* and toothed drum *B'*, by which it is straightened and cleansed.

Fig. 2357.



Hair-Rope Picker.

Digitized by Google

Hair-salt. (*Mining.*) A native sulphuret of magnesia occurring as a fine capillary incrustation.

Hair-side. (*Leather.*) The grain side.

Hair-space. (*Printing.*) The thinnest space used by printers.

Hair-spring. The recoil-spring of a watch-*balance*.

The balance is pulsating, and is the *time* measurer. It is driven in one direction by the power of the mainspring imparted through the escapement, and is returned by the power of the hair-spring, the running of the *train* of wheels being intermitted meanwhile.

It is one of the most delicate of steel articles, and is a favorite illustration of the value given to a cheap article by protracted manipulation.

Hair-springs are made of fine steel, which comes upon spools like thread. To the naked eye it is a round hair, but under a glass it is seen to be a flat steel ribbon, which the gage shows to be $\frac{2}{1000}$ of an inch in thickness, about one half the thickness of an average human hair.

A hair-spring weighs $\frac{1}{15000}$ of a pound Troy. In a straight line it is a foot long. It is exquisitely tempered, for it is to spring back and forth 18,000 times an hour, perhaps for several generations. A pound of steel in the bar may cost one dollar; in hair-springs it may be worth $4,000.

The hair-spring of a watch is usually a flat helix, but chronometer balance-springs are coiled cylindrically.

Hooke introduced the balance-spring into the watch. He made it straight. Huyghens soon after gave it the coiled form. This was about 200 years ago. We are indebted to this brilliant pair of philosophers and mechanicians for much that we enjoy in the approximate perfection of our instruments of precision, — mathematical, optical, and horological.

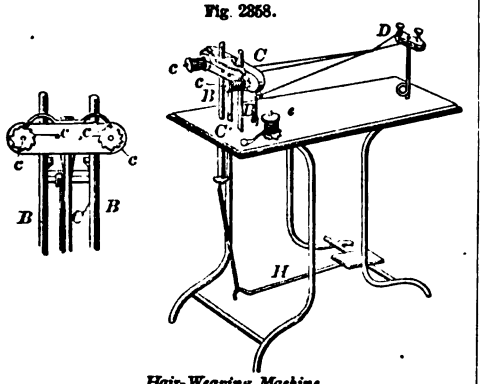
See under HOROLOGICAL INSTRUMENTS, etc.; CHRONOMETER; BALANCE, WATCH.

Hair-stroke. (*Printing.*) A fine line at the top or bottom of a letter; a ceriph.

Hair-trig'ger. (*Fire-arms.*) The secondary trigger of a gun. Its movement is effected by a very slight force, and unlocks a secondary spring device called a *hair*, which strikes the tumbler-catch and throws the sear out of the notch in the tumbler.

Hair-work'ing. A term which includes the making from human hair of bracelets, brooches,

Fig. 2358.



Hair-Weaving Machine.

ear-rings, rings, chains, necklaces, shawl-pins, purses, bags, book-markers, pencil-cases, guards, studs, etc. These are braiding or plaiting devices.

In the invention figured, designed for weaving hair for wigs, etc., the head *C*, carrying the spools *c c*, has vertical reciprocation on the pins *B B*, and is operated by the treadle *H*. The ends of the threads on the spools *c c c* are held by the clamp *D*. A slip of hair is passed between the upper side threads and the lower central one, the treadle depressed, the end of the hair turned, and the sliding head rises by the force of a spring. These operations are successively repeated.

Hake. A shed for drying draining-tiles.

Hal'berd. 1. A weapon formed of a blade on the end of a pole.

This was a common weapon among the Romans (*falx, falcula*), either short-handled like the English bill-hook, or on a long handle like the Tudor halberd. It differed from the *cultus* in having a curved cutting edge.

2. A piece of iron welded to the forepart of a horseshoe to relieve the toe of a lame horse.

Half-bas'tion. (*Fortification.*) A *demi-bastion*. That half of a bastion cut off by the capital, consisting of one base and one front.

Half-bent. The half-cock of a fire-lock.

Half-bind'ing. (*Bookbinding.*) A style of binding in which the backs and corners are of leather and the sides of paper or muslin.

Half-breadth Plan. (*Shipbuilding.*) A plan or top view of one half of a ship divided by a vertical longitudinal section in the line of the keel.

It shows the *water* lines, *bow and buttock* lines, and *diagonal* lines of construction.

Half-breadth Staff. (*Shipbuilding.*) A rod having marked upon it half the length of each beam in the ship.

Half-cap'o-niere'. (*Fortification.*) A communication in the dry ditch of a fortress, constructed with but one parapet and glacis.

Half-chess. (*Bridge-building.*) A short *chess* or platform board of a military bridge.

Half-cock. (*Fire-arms.*) The position of the gun-lock when the nose of the *sear* is in the first or deep *notch* of the *tumbler*. From this it cannot be pulled off by the trigger.

Half-cut Line. Flax cut in two lengths for spinning.

Half-floor. (*Shipbuilding.*) One of the timbers of a frame whose heel is over the keel, and upon whose head rests the heel of the second futtock. It lies for half its length alongside the cross-timber, and the other half alongside the first futtock.

Its heel butts against the heel of the corresponding timber of the other half of the frame, at the middle line of the ship, where they are clamped between the keel and keelson, and coaked or bolted thereto.

Half-fur'nace. (*Metallurgy.*) An ore-smelting furnace of but about 36 feet hight. The high furnace is 50 to 72 feet in hight.

Half-gang. (*Weaving.*) The part of warp of twenty threads, warped round the bank after a lease.

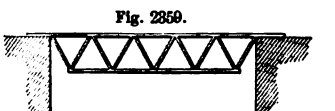
Half-head'er. (*Bricklaying.*) A half-brick laid at the angle of a building to finish the course.

Half-high Fur'nace. See HALF-FURNACE.

Half-hitch. (*Nautical.*) Passing the end of a rope round its standing part and then through the bight. A *clove-hitch* is two *half*-hitches. See HITCH; KNOT.

Half-lat'tice Gird'er. (*Bridge-building.*) A form of girder sometimes known as a "Warren Girder," and consisting of horizontal upper and lower

Fig. 2359.



Half-Lattice Girder.

Digitized by Google

bars, and a series of diagonal bars, sloping alternately in opposite directions, and dividing the space between the bars into a series of triangles. See TRUSS.

Half-mer'lon. (*Fortification.*) That solid portion of a parapet which is at the right or left extremity of a battery.

Half-min'ute Glass. (*Nautical.*) A sand-glass which determines the time for the running out of the log-line. See LOG.

Half-moon. (*Fortification.*) A *redan* in front of the *curtain* on the outside of the main ditch.

Half-moon Knife. (*Leather.*) A double-handled knife used by the dresser of skins for parchment. The knife has a crescent shape, and projects in a plane at right angles to the axis of the handles.

Half-pace. (*Building.*) *a.* A raised floor in a bay-window.

b. A resting-place at the end of a flight of steps. A *foot-pace.* A *landing.*

Half-pike. (*Nautical.*) A short pike employed in boarding.

Half-port. (*Nautical.*) A port-shutter having a hole for the protrusion of the gun-muzzle.

Half-prin'ci-pal. (*Carpentry.*) A rafter which does not extend to the crown of the roof. Their tops are connected by collar-beams, or rest on a purlin.

Half-re-lief'. The moderate prominence of a sculptured figure from the plain surface to which it is attached. It is also known as *mezzo-rilievo*, or *demi-relief*, and is a grade between *alto-rilievo* or *high-relief*, and *basso-rilievo* or *low-relief*.

Half-rip Saw. (*Carpentry.*) A species of hand-saw with a narrower set than a rip-saw and somewhat finer gage of teeth.

Half-round Bit. A demi-cylinder bit.

Half-round File. A file flat on one side and rounding on the other.

The curve usually varies from the half to the twelfth of a circle, but the name *half*-round is indiscriminately applied. Files with the larger curvature are known as *full* half-rounds; others as *flat* half-rounds.

Half-sheet. (*Printing.*) The off-cut portion of a duodecimo.

Half-shoe. (*Farriery.*) A shoe on the one side only of a horse's foot as a protection or corrective, when the horse is not fully shod.

Half-stuff. (*Paper-making.*) The partially ground rag-pulp, the produce of the *washing-engine*, which is the first of the two engines by which the reduction is made. See RAG-ENGINE.

Half-stuff Ma-chine'. (*Paper-making.*) A washing-machine in which ground rags are cleaned and cut to a greater degree of fineness than in the rag-engine. It resembles the *pulping-machine* in everything but being adapted to work on a coarser article.

Half-sunk'en Bat'tery. (*Fortification.*) A battery having its interior space or terre-plein sunk some inches below the natural surface, and its parapet composed of the earth thus obtained, and of that taken from a narrow ditch in front. This description of battery admits of being more quickly constructed than any other, as the diggers can work both in front and rear at the same time.

Half-thick File. A large, coarse file with three flat and one rounded side. It is used as a *rubber-file* for coarse work.

Half-tim'ber. 1. (*Shipbuilding.*) One of the short futtocks in the cant-body.

2. (*Carpentry.*) A mode of building houses practiced extensively in the Tudor times. The foundations and principal supports were of stout timber, and the interstices of the fronts were filled with plaster.

Half-tub. Half a cask cut off at right angles to the axis. Such is a deck tub, for swabs in deck-cleaning, and for gun-sponges on shipboard. Such is also the *match*-tub.

Half-turn'ing Bolt. One with a thread occupying one half of its cylindrical surface. See BOLT, *n.*

Hal'liard. See HALYARD.

Hal'lier. A birding net.

Hal'lo-type. (*Photography.*) Another name for the HELLENOTYPE (which see).

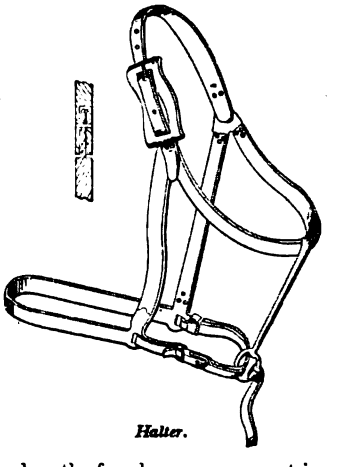
Ha-lom'e-ter. An instrument for measuring the forms and angles of salts and crystals.

Hal'o-scope. (*Optical.*) An optical instrument invented by M. Bravais for exhibiting the phenomena connected with halos, parahelia, etc. It comprises prisms and a mirror, which are rapidly revolved about an axis, and two plates of glass for intercepting the light. The rotating prisms receive the light from a lamp in a darkened chamber, the refracted rays assuming the form of the parahelion circle.

Hal'ser. A large rope. See HAWSER.

Hal'ter. (*Menage.*) A headstall and strap by which an animal is hitched to a stanchion or manger.

Fig. 2360.



Halter.

Cattle and calves were tied in stalls for fattening by the Hebrews. Horses and oxen were also stalled. Solomon had 40,000 horse-stalls. The animals were tied up by halters, no doubt. Headstalls for animals were common then in Babylon, Persepolis, and Egypt. The horses and asses of the Syrians were tied in their camp (892 B. C.) when the four leprous men went in and found the camp deserted.

Halters are shown in the sculptures of Nimrôud. The army is represented in the act of crossing a river, and the horses are haltered behind the sterns of the boats, swimming in the wake.

Hal'vans. (*Mining.*) Impure ores which require to be washed and freed from impurities.

Halve-net. A fixed bag-net placed within low-water mark to prevent fish returning with the tide.

Halv'ing. A mode of joining timbers or scantling in which each is equally cut upon one of its faces, and the two new faces are laid together and secured. The timbers *lap* upon and are *let into* each other.

The joint thus made may be a simple *lap-joint*, or it may be a *dovetail*, a *scarf*, or a *notched joint*. It may be secured by *pins*, *wedges*, or *bolts*, according to circumstances.

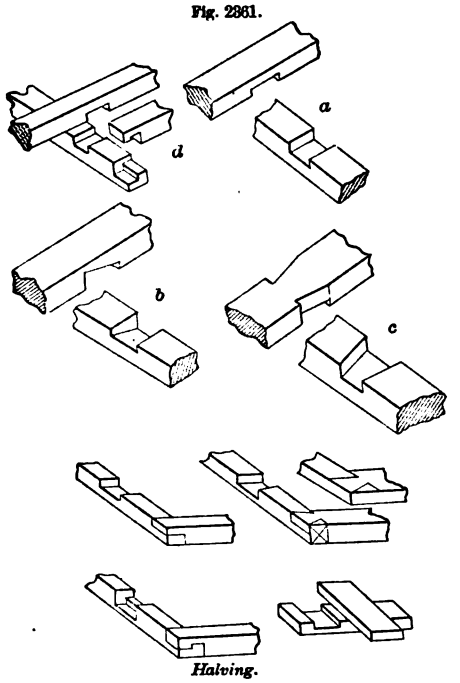
Among the varieties specific names are given to *a*, *common* halving; *b*, *beveled* halving; *c*, *dovetailed* halving; *d*, *notched* halving.

Halv'ing-belt. (*Machinery.*) A belt crossed between pulleys, so as to revolve them in opposite directions. A *crossed* belt. See BELT.

Hal'yard. (*Nautical.*) A rope, chain, or tackle

Digitized by Google

Fig. 2361.



Halving.

for hoisting or lowering *yards*, *spars*, *sails*, or *flags*. The halyards of the lower yards are called *jeers*. *Haulyard*; *halliard*.

They are named from the spar, etc., to which they are applied; as, —

The *throat* or *peak* halyards of a gaff.

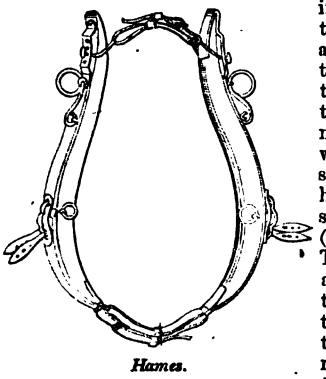
Main-sail, *top-sail* halyards, *driver*-halyards, etc.

Signal-halyards, *pendant*-halyards, *ensign*-halyards.

To haul a yard aloft is to *sway* it; to lower is called *striking*.

Hame. (*Harness.*) One of the pair of curved bars of wood or metal which fit in the crease between the roll and the body of the collar, and to which the traces are connected. The flat wooden hame is still used in heavy gears, secured by thongs (*hame-strings*). The trace-chains are attached to the hooks, and the reins pass through the rings above. The *trace-hooks* of carriage-hames are looped to the staples of the hames.

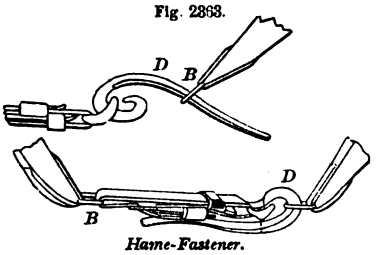
Fig. 2362.



Hames.

Hame-fas'ten-er. (*Harness.*) A device to fasten the ends of hames together, clasping them around the collar. A substitute for a hame-string. In the example, the device is buckled to one hame-loop *B*, and the hook *D* passed through the other loop. The hook is then turned over, as in the lower figure, tightening the hames.

Fig. 2363.



Hame-Fastener.

Hame-lock. A HAME-FASTENER (which see).

Hame-ring. (*Harness.*) With carriage-hames there is one ring on each hame for the driving-reins; with wagon-hames, an additional ring is provided on each for the breast chain or strap.

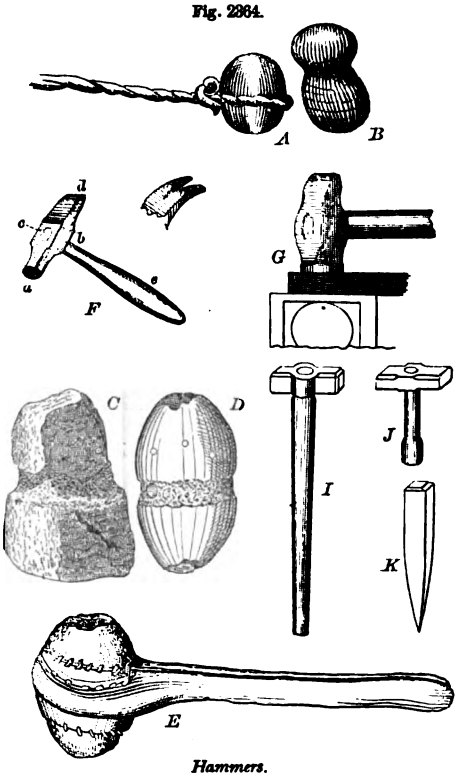
Hame-strap. (*Harness.*) A strap at the upper end of the hames unites them above the collar, and another strap unites them below the collar. The lower is the one which is unfastened to remove the gears.

Ham-knife. In some restaurants, a peculiar long, round-ended carving-knife for shaving off very thin slices of ham or beef.

Ham'mer. 1. A tool for driving nails, beating metals, and the like.

We can hardly admit the statement of Pliny that the hammer was invented by Cinyra, the discoverer of copper-mines in the island of Cyprus. Tools of metal, of which the hammer was among the first, must have been in use for many centuries. Tubal Cain, the descendant in the sixth generation from Cain, was an "artificer in brass and iron"; copper, probably, rather than brass. Brass and bronze are

Fig. 2364.



Hammers.

Digitized by Google

not distinguished from each other, by name, either in Greek or Latin.

The initial form was perhaps a stone fastened to a handle, and used as a club, *A B C D E*. Many such are found in the relics of the stone age, before man had learned the use of metal, the most useful of which, iron, was about the last to be discovered, of those which are applied to the common affairs of life. This stone age is so far in the remote past as to antedate all historical accounts of manners, customs, and appliances. The use of stone, however, in the mode described, still exists among many nations imperfectly provided with a better substitute. In the Bible we read of hammers for nails, forging, and planishing, and for breaking stone.

A B are ancient stone hammers, found in long-neglected workings of the Lake Superior copper region, and are identical with those of other parts of the world. It is not necessary to give them an equal antiquity to the "celts," stone axes and hammers of the stone age of Europe, as many of the implements yet in use among the more barbarous North American Indians are of the same general character. See AXE.

Modern hammers are of many shapes and kinds. The parts are the *handle* and *head*. The latter has an *eye*, *face*, *peen*, or *claw*.

F shows a riveting hammer. Of its parts *a* is the face, *b* the poll, *c* the eye, *d* the peen, *e* the helve.

G is a large hammer used by machinists. Between *F* and *G* is a *claw*, which takes the place of the *peen* of the other hammer. *I* and *J* are miners' hammers; *K* a miner's wedge.

Hammer-making forms a very important part of the industry of the great manufacturing center, Birmingham, and its satellite, Wolverhampton.

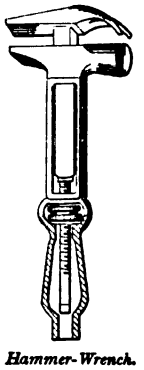
The nomenclature of the various kinds, which are numerous, is generally derived from their application, though in some instances from the form.

File-maker's, *sledge*, *riveting*, *lift*, *raising*, *claw*, *planishing*, *gold-beater's*, *hacking*, *veneering*, may be enumerated among the numerous varieties, as well as *tilt* and *steam hammers*.

Hammers employed in engine work are of three sizes, the *sledge*, *flogging*, and *hand* hammers. See also MINER'S HAMMER.

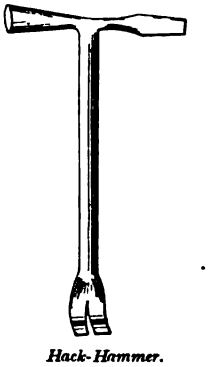
Fig. 2365 is a combined hammer and wrench.

Fig. 2365.



Hammer-Wrench.

Fig. 2366.



Hack-Hammer.

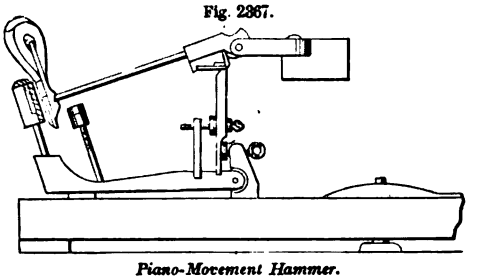
Fig. 2366 is a tack-hammer with claw handle and a sharp peen which forms a screw-driver.

The Japanese hammers are solid cylindrical pieces, not made shapely with waists and graceful outlines like ours. They have the same flat-sided handles as the saws.

2. The *striker* of a clock.

3. (*Fire-arms.*) Formerly, the hammer of the flint-lock was the steel cover of the priming-pan, and the parts connected therewith which received the blow of the flint which was held in the *cock*. With the old flint-lock, the parts of the *hammer* were the *body*, *face*, *back*, *seat*, the *heel* or *tail*, and the *toe*. The hammer of the percussion-lock is the striking part itself, — the *cock*. Such changes are not uncommon in mechanics. The piano-jack is another instance. See GUN-LOCK.

Fig. 2367.



Piano-Movement Hammer.

4. (*Music.*) A small padded mallet by which the string of a piano is struck.

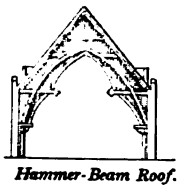
Wrench-hammer.

Ham'mer-axe. A double tool having a hammer at one side of the handle and an axe at the other.

Hammer-beam. (*Carpentry.*) A timber tie connecting the two rafters of a pair at a point between the apex and footings. A *collar-beam.*

Ham'mer-beam Roof. (*Carpentry.*) A roof, the feet of the principal rafters of which are not connected by a tie-beam, but usually rest in corbels.

Fig. 2838.



Hammer-Beam Roof.

Half-rafters, carrying a vaulted superstructure, usually partially span the severy.

Ham'mer-cap. A cover for the cock of a gun.

Ham'mer-catch'er. (*Music.*) A padded shoulder which catches the hammer on its return. See PIANO-MOVEMENT.

Ham'mer-cloth. (*Carriage.*) The cloth which covers a coach-box; so called from the old practice of carrying a hammer, nails, etc., in the box of the seat; or from *hamper.*

Ham'mer-hard'en-ing. Beating metal with a hammer while cold, to close the pores and condense the texture.

Ham'mer-helve. The shank of a forge or trip-hammer. On the *helve* is fastened the *hurst* or ring, which has projecting trunnions forming the axis.

Ham'mer-joint. The joint of the pan in the flint-lock.

Ham'mer-mark. A *forge-mark.* A mark of the hammer left from forging.

Ham'mer-nail. The pin securing the cock to the plate of the gun-lock. A *lock-nail.*

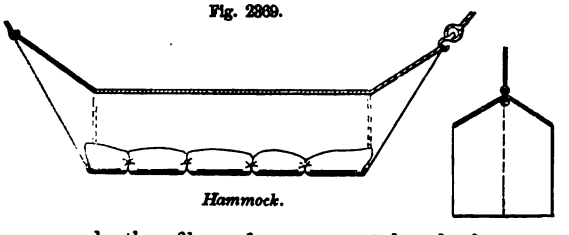
Ham'mer-spring. The spring of the hammer in a gun-lock. Its parts are the *play-side, stud-side,* the *turn,* the *flower,* the *stud,* the *eye;* through the latter passes the rod of the spring-pin.

Ham'mer-tail Spring. (*Horology.*) A long and stiff spring in a clock which gives the effective impulse to the striking hammer, when the latter is retracted for a blow and then released.

Ham'mock. (*Nautical.*) From *hamac;* the suspended bed of the Bahama-Islanders when discovered by Columbus.

A swinging sea-bed, common in South American countries and elsewhere, and made of manilla, sea-

Fig. 2839.



Hammock.

grass, and other fiber, often ornamented and of delicate material. "The undisputed invention of Alcibiades" (ADMIRAL SMYTH). It is a piece of canvas, 6 by 4 feet, the end gathered by *knittles* and a *grommet,* forming the *head* and *foot clews,* to which is attached the lanyard by which it is suspended from rings in the deck beams.

The illustration is rather a swinging cot.

The orders on board ship are, "Down all hammocks!" "Up all hammocks!" "Lash hammocks!" Their respective meanings are, to carry below and sling; to unsling and stow away; to brail up to allow a clear passage between decks.

Ham'mock-net-tings. (*Nautical.*) A row of forked, upright, iron stanchions, supporting a netting or wooden trough, in which the seamen stow their hammocks during the day.

Ham'per. 1. A large wicker-work covered basket, used for packing up liquors, etc., for carriage.

2. A fetter.

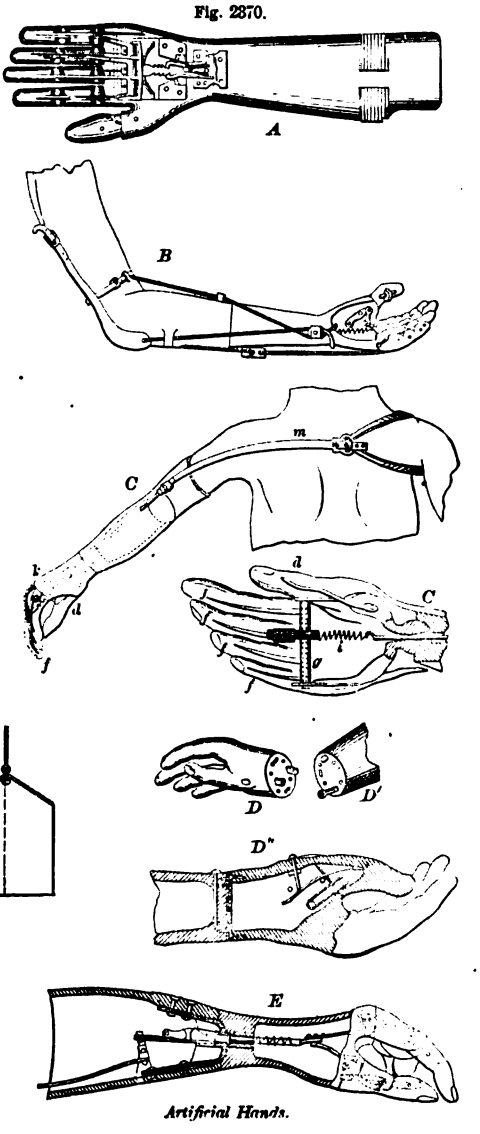
3. (*Nautical.*) Equipment and gear about the decks of a vessel.

Ha'mu-lus. (*Surgical.*) An instrument for extracting the fetus.

Hance. (*Architecture.*) The two lower portions of a four-centered arch; the part between the *haunch* (haunch) and the *springing.* *Haunch.*

Hand. 1. (*Horology.*) The pointer or index-finger of a watch, clock, or counter: *hour, minute, seconds,* as the case may be; or known by the dial

Fig. 2870.



Artificial Hands.

Digitized by Google

to which it belongs, as in the respective dials of the gas-meter or other dial-register.

2. (*Menage.*) Four inches; horse measure.

3. The small of a gun-stock.

4. A handle or helve.

Hand-an'vil. (*Locksmithing.*) A small movable anvil used by locksmiths. It may be supported by the work-bench or held in one hand. A *stake.*

Hand, Ar'ti-fi'cial. A prosthetic member to be attached to the stump of the forearm, and having fingers and a thumb with some capacity for grasping. The terminal portion of the artificial arm. See ARM, ARTIFICIAL, where the subject is considered at some length. Of mere hands and wrists a few examples may be given.

A is a hand in which the steel ligatures of the fingers are applied to a transverse rod which is connected to a toothed sliding bar; the position of the bar is regulated by two sliding pawls which can be operated by the other hand, and thus the fingers can be retained in any position.

B is for an amputation of the forearm, and has cords which pass from points of attachment on the arm so as to flex or extend the metacarpus and phalanges by the flexor and extensor movements of the stump.

C C are two views of the Selpho arm, in which the spiral spring *i* draws the fingers *f* constantly towards the thumb *d*, and retains any article placed within the hand and between the thumb and the fingers. The artificial hand may be opened by a motion of the opposite shoulder drawing on the shoulder strap *m* and cord *k*, or by extending the artificial hand and arm. *g* is a metallic cross-pipe on which the fingers are constructed.

D D' D'' are views of a hand which is detachable at the wrist. The clasps issuing from the artificial stump have sliding motion to clamp any article placed between their claws. These clasps enter slots in the wrist-plate of the hand. The thumb is adjustable in two positions by means of a spring and catch, the latter being freed by a trigger.

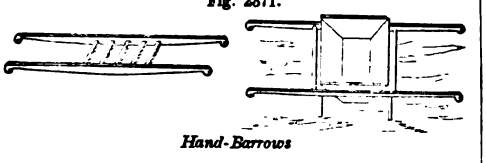
The spring thumb has a latch for holding it open when desired, and means for releasing the thumb from the latch when required.

In *E*, the detachable hand is so fitted to the forearm as to admit of a natural degree of rotary motion at the wrist, and that the hand may be detached by simply unlatching and withdrawing it from the socket without the trouble and delay usually necessary in disuniting the mechanism employed in moving the fingers. In place of the hand a grasping claw, having a swiveling socket, may be attached to the arm at will.

Hand-axe. A light axe which may be used in one hand in the manner of a hatchet.

Hand-bar'row. A device which has a pair of handles at each end, and is adapted to be carried by two men. A *hand-bearer*, *litter*, *bier*, or *stretcher.*

Fig. 2371.



Hand-Barrows

The difference is in the fitting up. The hand-barrow is intended for a load of packages, goods, or materials, and the illustrations explain its structure.

Hand-bell. A small bell with a handle, used for various purposes. They are sometimes silver-plated or gilt, or even of solid silver. The illustration shows an *altar*-bell for church service.

Fig. 2372.

Hand-Bell.

Hand-bill. A bill-hook. A chopping tool. See BILL-HOOK.

Hand-board. One used in rolling port-fire cases and similar work.

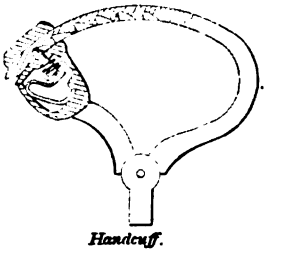
Hand-bor'er. (*Well-boring.*) A *pitching-borer* or *short borer* used at the commencement of a well or shaft.

Hand-brace. A tool for boring, consisting of a cranked spindle, at one end of which a broad head or breast-plate is attached by a swivel; at the other end a socket, into which a drill can be fixed. See BRACE.

Hand-car. A car for laborers or track-repairers, and adapted to travel on a railway, being propelled by hand-cranks.

Hand-cart. A two-wheel vehicle, its body balanced on its axle, adapted to carry loads of parcels or goods, and propelled by hand. The varieties are somewhat numerous, but preserve the general features stated.

Fig 2373.



Handcuff.

Hand'cuff. Usually in the plural, *hand-cuffs.* A chain and locking-rings; a strap or other *manacle* for the hands. That in the example may be closed fast by slipping the parts together, but the spring-bolt can only be disengaged by a key.

Hand-cul'ti-va'tor. (*Agriculture.*) One on a small scale, adapted to be drawn or propelled by manual power.

Hand-drill. A drilling-tool for metal, operated by hand, in contradistinction to a drilling-machine.

The cut shows a drill mounted on a bench by means of a clamping vise. *A B* represent two positions of the drill, one arranged for oblique presentation and the other for vertical.

C is a drill in which pressure is applied by the foot, and motion by the hand. *D* is a common hand-drill, with a cast frame. *E F* are side and front elevations of Nasmyth's drill.

There are many other forms of hand-drills, such as ratchet, bow, dental, Persian drills, etc. See list under DRILL.

Hand Feed-pump. (*Nautical.*) A deck feed-pump.

Hand-file. A somewhat generic term, including most forms of files. See FILE.

Hand-gear. (*Steam-engine.*) The handles of the working gear. The parts by which the driver controls the action of the engine; three sets of levers and rods connected to the slide-valve, eccentric-rods, regulator-valves, and feed-pipe cocks, whereby he can *put on* or *shut off* steam to the cylinders, water to the boiler, or place the slide-valves in a *forward* or *backward* position at his pleasure.

Hand-glass. 1. A bell glass or glazed frame, for the protection of plants.

2. A half-minute glass, used as a measurer of time in running out the log-line. See LOG.

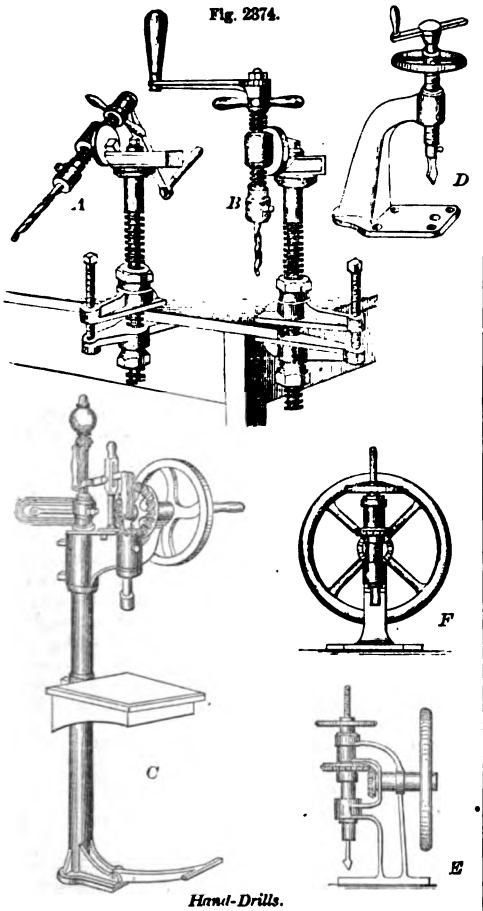
3. A small mirror with a handle.

Hand-grap'nel. (*Nautical.*) A small anchor.

Hand-gre-nade'. An explosive projectile of small weight; a shell adapted to be thrown by

Digitized by Google

Fig. 2374.



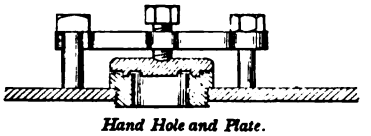
Hand-Drills.

hand, and used of course at near quarters. It is principally used in repelling an attack, being thrown over the parapet at the assaulting party. Also boarding-parties at sea. See GRENADE.

Hand-ham'mer. The machinist's working hammer used in engine and boiler work, in contradistinction to the two-handed *flogging* hammer and the *sledge.*

Hand-hole. (*Steam-boiler.*) A small hole at or near the bottom of a boiler, for the insertion of

Fig. 2375.



Hand Hole and Plate.

the hand in cleaning, etc. It is closed by a *hand-hole* plate, and is smaller than a manhole.

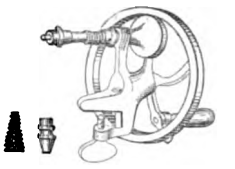
Hand-hook. 1. (*Forging.*) A bent instrument used by smiths in twisting square iron.

2. A hook for handling shells. A *shell-hook.*

Hand-jack. A jack worked by hand or by a lever, pinion and rack, screw, etc. See list under JACK.

Hand-lathe. 1. A small lathe mounted on a bench or table and turned by a hand-crank or by a bow. It is usually portable, and may be secured by a clamp to the bench. It is used by watch and clock makers, dentists, and other workers in small machinery.

Fig. 2376



Hand-Lathe.

2. A *bar-lathe;* one whose puppets slide on a prismatic bar.

Han'dle. A portion of or added to a tool, by which it is grasped. The *hand-hold.*

The *helve* of a hammer or axe.

The *haft* of a knife.

The *hilt* of a sword.

The *stale, staff,* or *stilt* of a plough.

The *stale* of a rake. Qy. from *hale,* to pull or draw.

The *stock* of a drill, bit, or gun.

The *bail* of a kettle.

The *rounce* of a printing-press, by which the form is run in and out, under and away from the platen.

The *shaft* of a boat-hook, spear, lance, or harpoon.

The *hand-lever* of a steam-engine, by which it is started, reversed, etc.

The *knob* of a door, or lock.

The *brake* or *lever* of a pump.

The *crank* of a winch or crab.

The *nib* of a scythe.

The *pommel* of a saddle.

The *trigger* of a gun-lock.

The *helm* or *tiller* of a rudder.

The *dolphin* of a gun. In bronze guns of the old construction handles were usually cast over the center of gravity of the piece, for convenience of handling and slinging. These were formerly made in the shape of a fish, and hence were called *dolphins.*

Handles for case or pocket knives are made of various materials: elephant and walrus ivory; stag, buffalo, and cow horn; tortoise-shell, bone, mother-of-pearl; cocoa, snake, rosewood, etc.

With *case knives* or *table knives* the tang of the blade is secured in the haft by means of cement, transverse rivet, end nut on the through tang, spring catch, or other device. Balance handles are made by introducing lead into the handle to counterbalance the weight of the blade.

With *pocket knives* the sides of ivory, horn, bone, wood, etc., are secured by rivets to the *scales,* as the side-plates of iron or brass are called.

Machines for making handles are of the nature of lathes, planers, etc., according to the material and the shape required. By such means are manufactured in quantity handles for brooms, scythes, shovels, chisels, whips, plows, etc.

Hand-lead. (*Nautical.*) A small lead for sounding; the term is used in contradistinction to *deep-sea lead.*

The hand-lead weighs from 7 to 11 pounds, and is used with 20 fathoms of line. See SOUNDING.

Hand'ler. (*Tanning.*) A pit containing a weak ooze for the early portion of the tanning process.

Pits containing a stronger solution, and used towards the conclusion of the process, are called *bloomers.*

Hand-let'ter. (*Bookbinding.*) A finisher's hand-tool whose face is a single letter.

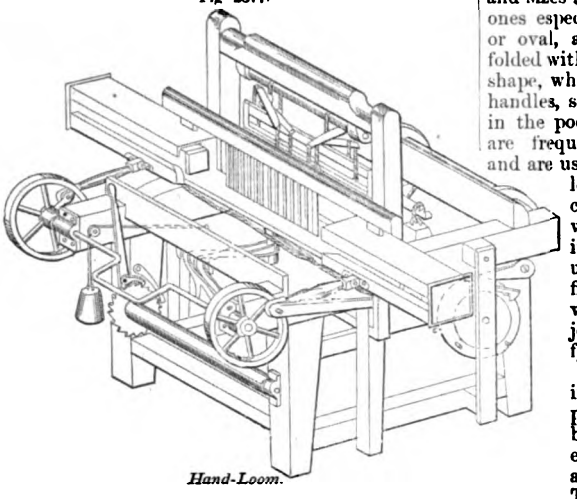
Hand'ling. (*Leather-manufacture.*) An occasional removal of hides from the vat, allowing them to drain, and then replacing them. The object is to equalize the action of the lime in the process of *unhairing;* of the ooze in tanning, etc.

Hand-loom. A form of loom in which the motions are derived from hand power, either by a crank or by pushing the lathe or batten. In the example,

Digitized by Google

the driving shaft, at the front end of the machine, is provided at its middle with a crank, so as to enable the weaver to use both hands when required,

Fig 2377.

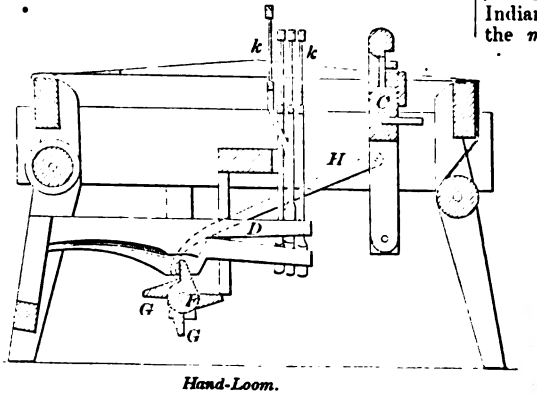


Hand-Loom.

and also to reach any broken thread in the warp. A feed pawl attached to a fly-wheel on the driving shaft operates a ratchet-wheel on a rearward shaft, provided with tappets which depress in succession the treadles. The picker staff projects from a shaft journaled vertically to the batten, and on this shaft is a strap, the ends of which are divided and secured to the alternate treadles. Thus the harness, let-off, take-up, and shuttle motions are all derived from the crank which is by the breast of the weaver.

Fig. 2378 is an example of the other kind, in

Fig. 2378.



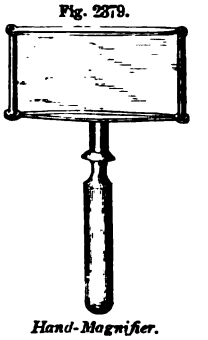
Hand-Loom.

which the motions are all derived from the batten *C*, in which is the shuttle-race. The harness levers *D* are actuated by means of a hooked arm *H* engaging cams *G G* on a shaft *F*. The upright rods *k k* carrying the harness are interchangeable on the treadles, in order to vary the twill or style of the cloth. See LOOM, p. 1354.

Hand-made. (*Paper.*) Said of paper made with a wire-cloth and deckel, by slipping out a quantity of pulp, allowing a partial drainage, and then transferring the mat to the felts.

Hand-mag'ni-fi'er. A lens, usually of doubly convex form, mounted and provided with a handle. They are of various shapes and sizes; some, the smaller ones especially, being round or oval, and adapted to be folded within a case of similar shape, which constitutes the handles, so as to be carried in the pocket. Larger ones are frequently rectangular, and are used as readers. The lens may be of meniscus or concavo-convex form, to adapt it to the sight of the user, having a large field of view, for convenience in reading print or viewing objects which do not require a large magnifying power.

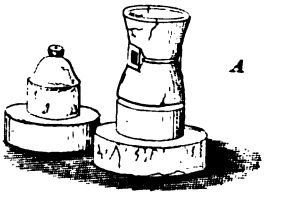
Fig. 2379.



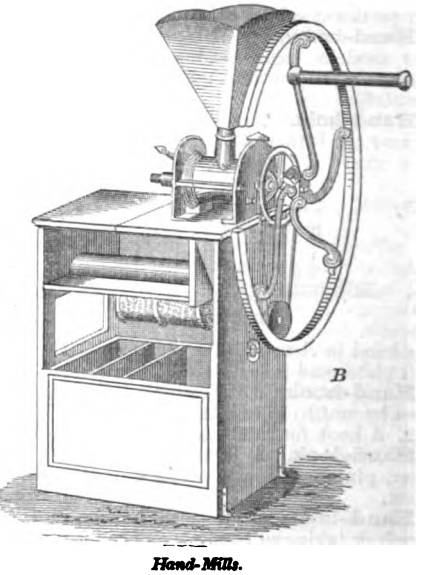
Hand-Magnifier.

Hand-mill. The original mode of making meal was by bruising the grain. This plan was earlier than any form of grinding by a mill. In the time of Pliny one variety of bread was made from pounded grain, and was highly esteemed. (See BREAD.) The references to mills in the Bible all concern the hand-mill, which was universal throughout the Orient, the references to it in old writings, the illustrations of old monuments, and the remains of the machine itself, being very numerous and widely scattered. *A* (Fig. 2380) represents two mills of Pompeii. A golden hand-mill was one of the most honorable presents from a Persian king to a subject.

Fig 2380.



The Romans found the British in possession of the *quern*. The North American Indians adhered to the *mortar*, and the



Hand-Mills.

Digitized by Google

hollowed stones yet mark the sites of their villages in those parts where corn was cultivated. The Mexicans use a spindle-shaped rub-stone in a hollow bed-stone.

The almost universal form of hand-mill was two circular stones, the lower was the bed-stone and stationary, and had a central pivot for the upper one, which had an eye. The upper stone was turned by means of a vertical handle. See GRINDING-MILL.

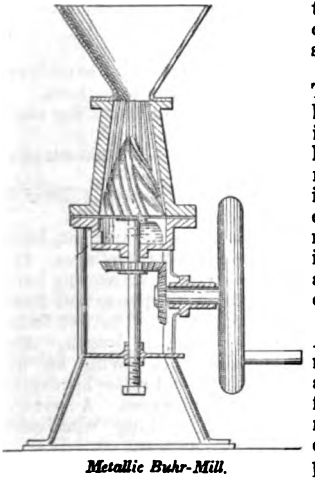
The mill adopted by Napoleon, and used by him in his invasion of Russia in 1812, consisted of two circular cast-iron plates, about 12 inches in diameter, placed in a vertical position. One was fixed, the other rotated by a hand-crank. The plates were indented all over with radiating grooves, and the corn was conducted to the center, or eye, by a lateral hopper. The meal, as it was ground, was projected from the periphery by the centrifugal force of the revolving plate.

Hebert's hand-mill (English) is adapted to grind and dress; an annular surface of fine wire gauze surrounding the bed-stone receives the meal as it issues from beneath the stone. Brushes on the skirt of the runner pass continually over the wire gauze and drive the flour through the interstices, while the offal is swept to an opening and carried by a chute to a separating sieve, which sorts it into grades.

The mill *B* has a conical grinder, and the meal falls into a rotating sieve which sorts it into flour, shorts, and bran. The fly-wheel is shown partly broken away to expose the parts more fully. See GRINDING-MILL; COFFEE-MILL.

Fig. 2381 is a hand-mill in which a conoidal metallic buhr works on a vertical axis in a conical serrated shell.

Fig. 2381



Metallic Buhr-Mill.

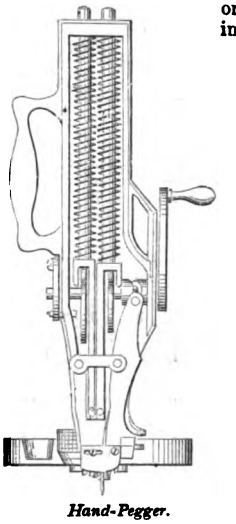
Hand-mold. The mold in which hand-made type is cast. It has a lip to receive the metal which runs into the mold containing the matrix. The mold is then opened and the type drops out.

Hand-or'gan. An organ arranged to play automatically from a rotatory motion; its parts consisting of the pipes, arranged vertically in the front, the barrel, placed at the top and back, the keys, vertical between the two, the bellows under the barrel, and the *grinding* and *shifting* gear at the side. The barrel extends the length of the hand-organ, and is about four or five inches in diameter. This has little brass staples of a length corresponding to that of the note, and which, when the barrel revolves, open the pipe valves. They project about an eighth of an inch above the cylinder, and for each tune are allowed one sixteenth of an inch along the length of the barrel to every key, the latter being placed at a distance apart corresponding to the number of tunes. One revolution invariably plays the whole tune, and longer tunes have to be cut down to this, except for regular operatic organs, where an automatic shifting apparatus is used. Otherwise the barrel is shifted by gear at the side under control of the grinder, which makes a difference of one sixteenth one way or the other along the barrel. The pipes are made from hard wood, as boxwood, or from reeds. The blast for them is furnished by the bellows, which is worked by gear from the crank, like the barrel. The keys resemble those ordinarily used in musical instruments. The most important part of the manufacture consists in arranging the position of the points or staples of the barrel. An ordinary piece of sheet music is before the workman, and the barrel of a hand-organ is mounted below it so as to revolve with a large wheel at his left hand. This wheel is divided up into parts which correspond to the bars in music. Above the barrel are a set of keys, with little teeth that indent the paper wound around the barrel. He sits down before the instrument, revolves the wheel one bar, and strikes with a hammer the proper keys, then revolves again, and so on. The indentations mark the places for the brass points and staples, which another man inserts.

Hand-peg'ger. A portable pegging-machine, operated by hand and fed around the shoe, the operator holding the machine in a vertical position and turning a crank which sets all its working parts in motion.

The illustration shows a machine which is held upon the sole of the boot or shoe by one hand of the operator, who turns the crank with the other. The awl is first driven through the sole, and as it rises the machine feeds itself along the distance between the pegs, which brings the peg end of the strip over the hole just punched; the peg is then cut off and driven down by the plunger which holds it, and the end trimmed off by the machine.

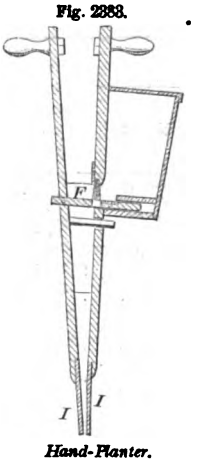
Fig. 2382.



Hand-Pegger.

Hand-plant'er. A corn-planter carried in the hands, or by one hand, and thrust into the ground like a stick.

Fig. 2383.



Hand-Planter.

The thrust and lift usually work the seed-slide, but in some two-handed planters, as in the example, the thrusting together of the portions opens the plates *I I* and allows the seed to drop into the ground. Pulling the handles apart works the slide *F*, and draws seed from the box ready for the next hill. See CORN-PLANTER.

Hand-pump. 1. (*Steam-engine.*) A pump placed alongside the fire-box of a locomotive and

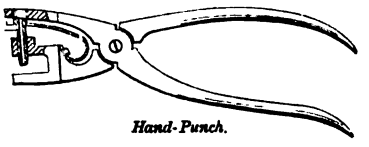
Digitized by Google

worked by a hand-lever, to feed the boiler when the engine has to stand with steam up. The Giffard injector obviates the necessity for a hand-pump, as it is always operative when steam is up. Hand-pumps are also arranged for other engines. Small auxiliary boiler-feeding engines are used for the Western rivers.

2. An ordinary small pump for domestic and other uses; as distinguished from a power pump. See list under PUMP.

Hand-punch. A punch for perforating tickets, leather, or paper, for the insertion of eyelets or for

Fig. 2384.



Hand-Punch.

other purposes. It has a cutting tube and an anvil, or a punch and hollow die. The conductor's punch is a familiar instance.

Hand-rail. 1. The horizontal rail of a balcony, a baluster, on a stairs, or along the sides of a locomotive engine, to protect the engineer in going forward and back on the engine.

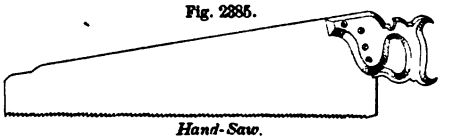
2. Also on the companion and quarter-deck ladders, on the break of the poop, quarter-deck, or forecastle, permanent gangway ladders, etc.

Hand-rail Plane. A round-soled plane for dressing the upper surface of a baluster rail. A *capping* plane.

Hand-saw. A saw riveted at one end to the handle, and adapted to be driven by one hand.

There are several grades and some variations.

Fig. 2385.



Hand-Saw.

NAMES.	Length in Inches.	Breadth in Inches. At Handle.	Breadth in Inches. At End.	Thickness in Inch'a	Teeth to the Inch.
Without Backs.					
Rip saw	28-30	7 -9	3 -4	0.05	3½
Half-rip saw	26-28	6 -8	3 -3½	0 042	4
Hand-saw	22-24	5 -7½	2½-3	0.042	5
Broken-space saw	22-24	5 -7½	2½-3	0.042	6

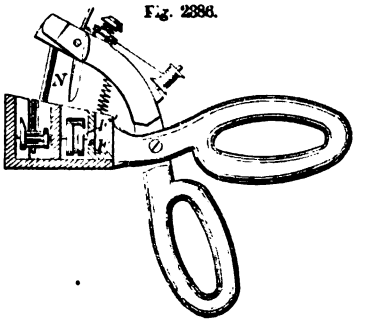
Carcass-saw	10-14	2 -3		0.025	12
Dovetail-saw	6-10	1½-2		0.022	14-18

Hand-screw. A jack-screw used for raising heavy weights. See SCREW-JACK.

Hand Sew'ing-ma-chine'. A form of sewing-machine in which the parts are pivoted jaws, operated in the manner of scissors. The machine illustrated employs two threads to form a lock-stitch. The looping-hook *E* makes a reciprocating instead of a continuous revolution around the disk bobbin *F*. The bobbin and looping-hook are contained in one part, and the eye-pointed needle *N* is attached to the other portion. There are other forms.

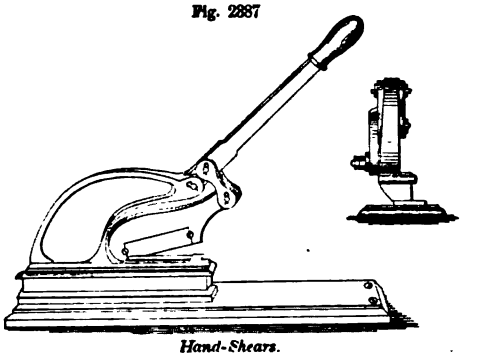
Fig. 2386.



Hand Sewing-Machine.

Hand-shears. (*Metal-working.*) *a.* A machine for cutting metallic plates, having a reciprocating

Fig. 2387



Hand-Shears.

knife, cutting shearwise, and moved by a hand-lever. The illustration shows side and end elevations.

b. Snips. Shears used by hand in cutting sheet-metal.

Hand-shut'tle. (*Weaving.*) The common shuttle as distinguished from the *fly-shuttle.*

Hand'spike. A loose bar forming a lever for lifting or shifting an object.

In the United States ordnance department, handspikes are commonly made of three sizes, viz.: trail handspikes for field service, maneuvering handspikes for siege and garrison purposes, and handspikes for mechanical maneuvers. The two former are 66, and the latter 84 inches in length. *Shod* handspikes — that is, handspikes having an iron plate under their lower end — and *roller* handspikes are also employed for certain purposes. A *heaver.*

Handspikes are used in working windlasses; those for capstans are known as *bars.*

Hand'spike-ring. (*Artillery.*) The thimble on the trail transom of the gun, for the handspike by which it is maneuvered.

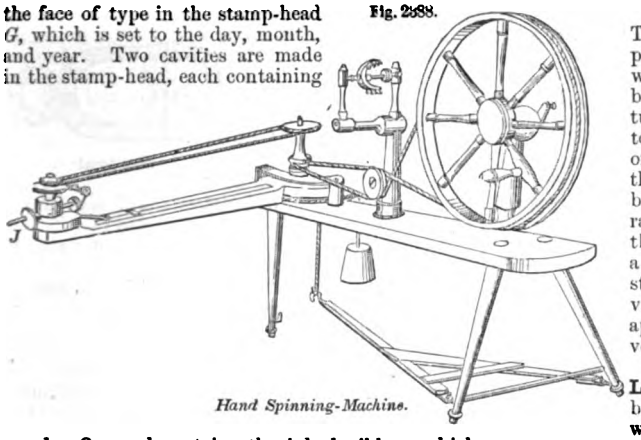
Hand Spin'ning-ma-chine'. A form of spinning-machine in which a carding is fed by hand to the spindle, which is revolved by a cord from a large wheel, driven by the hand in the intervals of piecing on new lengths of carding. The usual form of rustic spinning-machine is familiar, but the example is intended to allow a person to sit and spin, the spindle *J* being carried away from the person by pressure on the treadle instead of the person walking backward from the spindle to draw out the carding.

Hand-stamp. One for canceling, dating, or addressing papers, envelopes, documents, etc. The example has a colored ribbon, which is drawn over

Digitized by Google

the face of type in the stamp-head *G*, which is set to the day, month, and year. Two cavities are made in the stamp-head, each containing

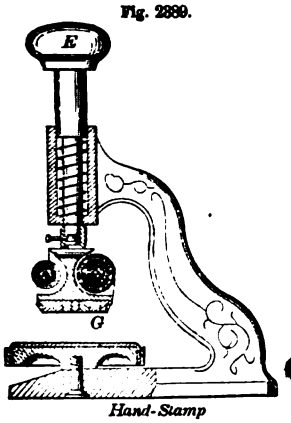
Fig. 2388.



Hand Spinning-Machine.

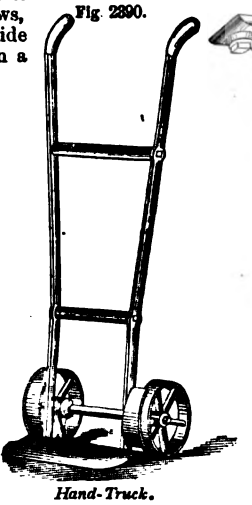
a reel. One reel contains the inked ribbon, which is led under the head over the type, and is rolled up on the other reel. This head is secured to its stem by two screws, one catching in a nick in one side of the plate, and the other in a

Fig. 2389.



Hand-Stamp

Fig. 2390.



Hand-Truck.

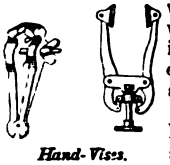
segmental slot on the opposite side. The head is depressed by a blow on the head *E* of the spring plunger.

Hand-swipe. A water-raising device. The *well-sweep* or well-pole of the West; the shadûf of Egypt and Syria. See SHADUF.

Hand-truck. A small truck used in mills, shops, and warehouses.

Hand-vise. A small vise for holding an article while it is being filed, shaped, bored, heated, or otherwise. A common form is a vise with a tang, in some cases driven into a handle. The jaws are operated by a thumb-screw. It is also known as a tail-vise.

Fig. 2391.



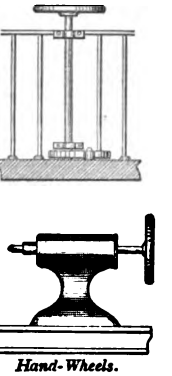
Hand-Vises.

The figure on the right is a hand-vise or clamp whose jaws are swiveled to the arms and are opened or closed by the traversing nut and connecting links; the cheeks of the jaws may be presented outward or inward.

When of peculiar forms, these implements have names indicative of their shape; as, *dog-nose, pig-nose hand-vise, cross-chap* vise.

Hand-wheel. The term is applied to wheels which are turned by hand to actuate machinery, to set it in motion or to stop it. As the wheel on the brake-shaft of a railroad car; on the tail center of a lathe; on the stem of a throttle-valve, etc. The applications are very numerous.

Fig. 2392.

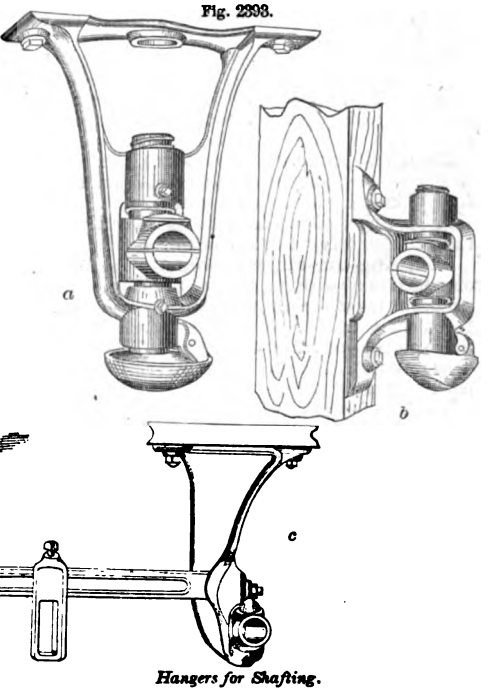


Hand-Wheels.

Hand-wheel Lathe. A small-bench lathe in which the spindle in the head-stock is turned by hand.

Hang. (*Shipbuilding.*) The curvature, concave on the downward edge, of a plank or strake when bent to the frames of a ship. A curve in the reverse direction is called *sny*.

Fig. 2393.



Hangers for Shafting.

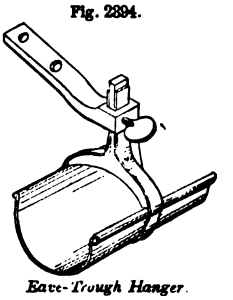
Hang'er. 1. A means for supporting shafting of machinery. The illustrations show several kinds.

a is a ball and socket hanger adapted to be attached to a joist or beam of the ceiling of a machine-shop.

b is a hanger attached to a post.

c is a countershaft

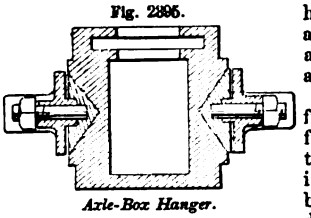
Fig. 2394.



Eave-Trough Hanger.

Digitized by Google

Fig. 2395.



Axle-Box Hanger.

hanger; has a ball and socket joint, and a belt-shifter arm.

2. A pedestal or frame dependent from the car or truck body, and in which the axle-box moves up and down as the springs contract and expand. (Fig. 2393.)

3. A means of suspending an object, as of spouting at the eave of a house (Fig. 2394), a cage, a basket, or what not. An overhanging bracket.

4. A seaman's cutlass; a short curved sword.

5. (*Weaving.*) The lower part of the heddle, or the lower heddle of the harness of a fancy loom.

Hang'ing-bridge. 1. (*Steam.*) A hollow, vertical partition depending from the bottom of a boiler and serving to deflect the flame. The *hollow* forms a part of the water-space of the boiler. The usual water-bridge rises from the furnace floor at the rear of the grate space.

2. *a.* A suspension bridge.

b. A truss-frame bridge.

Hang'ing-but'tress. (*Masonry.*) A buttress supported on a corbel.

Hang'ing-com'pass. (*Nautical.*) A suspended overhead compass in a cabin, viewed from below; known as a *tell-tale.*

Hang'ing-knee. (*Shipbuilding.*) One fayed vertically to the side, under the *deck-beam* knees, or *lodging* knees, which are horizontal.

A *hanging standard* knee is one directly beneath the beam, and fayed to it and to the side.

Hang'ing-ma-chine'. (*Bleaching.*) A machine on which cloth is hung to dry. It usually has tenter hooks for stretching the cloth by its edges. See HOOK-FRAME.

Hang'ing-post. (*Carpentry.*) That to which a door or gate is hinged. The other is the *shutting* post.

The *hanging stile* of a door is that one whose vertical edge has the hinges.

Hang'ings. Wall coverings, such as arras, tapestry, or paper.

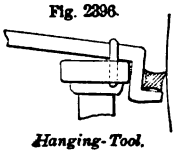
Hang'ing-side. (*Mining.*) The overhanging side of an inclined or *hading* vein.

Hang'ing-stile. (*Joinery.*) That stile of a door to which the hinges are attached.

Hang'ing-tie. (*Architecture.*) A tie which is supported by strap and collar, dependent from the rafters above.

Hang'ing-tool. (*Iron-turning.*) A crooked tool, which partially embraces the rest so as not to be easily displaced. The cutter is formed with hollow faces to facilitate grinding. It is used for smoothing the surfaces of iron ordnance, rollers, and similar objects.

Fig. 2396.



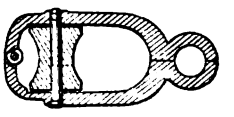
Hanging-Tool.

Hang'ing-valve. A hinged and gravitating valve in a rotary pump or engine, which falls down and forms an abutment, but is lifted by the passing piston so as to close an opening in the annular chamber while the piston is passing. A *clack*-valve. A *flap*-valve. See list under VALVE.

Hank. 1. (*Nautical.*) One of the *hoops* or rings of ash or iron to which the *weather-leech* of a *fore-and-aft* sail is *bent*, and by which it slides on the mast or stay, in hoisting by the *halyards* or lowering by the *downhaul.*

Sometimes the *head* of a *spanker* or *try-sail* is bent to *hanks* which slip on the *gaff.*

Fig. 2397.



Sail-Hank.

2. (*Yarn.*) *a.* Two or more skeins of yarn, silk, wool, or cotton, tied together.

A *hank* of *cotton* yarn is 840 yards in length, and consists of 7 *lays* of 120 yards each.

It is wound on a reel 4½ feet in circumference, 80 revolutions of which make a *lay.*

The *hanks* of cotton yarn are rated by the number which it takes to make a pound.

Throstle-spinning is seldom employed for yarns above Nos. 40 to 50, but with *mule*-spinning very high numbers have been reached. Previous to the introduction of the mule, few spinners could make yarn over No. 200. The natives of India, however, in their patient way and humid climate, made Nos. 300 to 400. Houldsworth, of Manchester, England, has made No. 700, which was woven in France. He is stated to have reached No. 10,000, a fineness beyond all useful range, but interesting as illustrating the perfection and capacity of his machinery.

b. A measure of 3,000 yards of *linen* yarn.

Table.

300 yards = 1 lea.
10 leas, 3,000 yards = 1 hank.
20 hanks, 60,000 yards = 1 bundle.

Han'som. (*Vehicle.*) A kind of cab, named after the inventor, in which the driver's perch is behind the cover of the occupant's seat, the reins passing above the hooded top.

Har'bor. 1. (*Hydraulic Engineering.*) A shelter for ships, where they may moor or ride at anchor.

2. (*Glass-making.*) A chest, 6 or 7 feet long, in which the ingredients for a charge are mixed and held.

Hard. 1. (*Hydraulic Engineering.*) A hard bottom of gravel laid across a swamp or at a muddy boat-landing.

2. The coarse part of flax. *Hurds.*

Hard'en-ing. 1. (*Metal-working.*) The process of giving an additional hardness to metallic articles after leaving the hands of the workman shaper.

Hammering and rolling will confer hardness, and in the reduction and shaping of articles by these means it becomes necessary to alternate annealing with the condensing processes.

The hardening of steel is accomplished by heating it to a certain temperature and then suddenly quenching it in water or oil. When the article is not required to be at its ultimate hardness it is *tempered* by *letting down* the temper. This is done by heating the article, observing the change of color. See TEMPERING.

Copper alloys for gongs are hardened by another process, in some respects the reverse of that adopted for steel. See ANNEALING.

Iron is surface hardened by heating to a bright red, sprinkling with prussiate of potash, allowing to cool to a dull red, and cooling with water. Two recipes: —

Prussiate of potash . . .	3	1
Sal-ammoniac	1	2
Bone-dust		2

Or heat pieces of horn, hoof, bone-dust, or shreds of leather, together with the article to be case-hardened, in an iron box, bring to a blood-red heat, then-

Digitized by Google

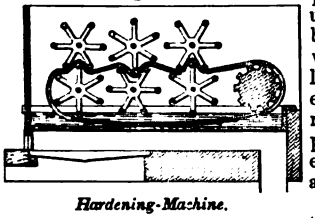
immerse the article in cold water. Some cut up the shreds, etc., fine, and mix them with white wine, vinegar, and salt.

2. (*Hat-making.*) The process of pressing together the light layer of filaments collected in the *basket*, so as to form it into a sheet of *felt* with sufficient cohesion to bear handling. The hands and then a *skin* are employed to produce this effect, the pressure, rubbing, and jerking causing the filaments to interlace and become felted, the body gaining consistence and hardness at the expense of its bulk and area.

3. A process of heating in the course of porcelain making. See HARDENING-KILN.

Hard'en-ing-fur'nace. (*Hat-making.*) A furnace with an upper plate of iron, upon which hat-bodies, folded in wet cloths, are laid to be hardened by heat, moisture, and the pressure of traversing plates above.

Fig. 2398.



Hardening-Machine.

In the example, the fabric with its inclosing envelope is attached to the endless band, and carried alternately through the pan of hot liquid and between the star-shaped rollers, which causes the fur to work into the felted body of the hat and firmly adhere. The furnace has a descending flue for convenience in conveying away the smoke. The liquid in the pan may be a solution of sulphuric acid and water. The star-shaped rollers are moved by suitable gearing outside the tank.

Hard'en-ing-kiln. (*Porcelain.*) A kiln in which printed biscuit is placed in order to drive off the oil of the color previous to glazing. See PRESS-PRINTING.

Hard'en-ing-skin. (*Hat-making.*) A piece of half-tanned leather laid above a *bat* of felting hair while the latter is compressed by the hands of the workman.

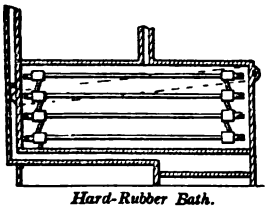
Hard-fin'ish. (*Plastering.*) Fine stuff applied with a trowel to the depth of about one eighth of an inch.

Hard Por'ce-lain. A ware composed of a natural clay containing silex (*kaolin*), and a compound of silica and lime, i. e. a quartzose felspar (*petuntze*). The glaze is also earthy, not metallic.

Hard Rub'ber. India-rubber mixed with a large proportion of sulphur, and subjected to an extreme heat. Other mineral substances, as white-lead, are also generally added. See CAOUTCHOUC; EBONITE.

In Mullee's process, the rubber, after washing, is rolled into sheets $\frac{1}{16}$ of an inch thick, and immediately placed in the sulphur-bath vessel in a horizontal position. The sulphur is kept at a temperature of 220° F. until foam has ceased to rise. At the expiration of the first hour, the heat is raised to from 30 to 40 pounds' pressure, and continued for a second hour, after which it may be allowed to rise to 80 pounds. The whole process takes from 5 to 10 hours. The sulphur used is known as "pure sulphur." Twenty or thirty minutes is sufficient for one immersion, after which the sheets are torn apart, rekneaded, and rolled into sheets. See VULCANITE.

Fig. 2399.



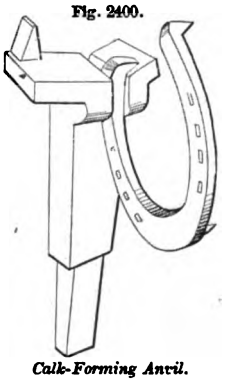
Hard-Rubber Bath.

Hard Sol'der. The solder used for uniting the more infusible metals. Spelter solder and silver solder are the two principal varieties. The former, for copper and iron, is sometimes made in the proportion of 16 parts copper to 12 zinc; more frequently equal proportions of the two metals are employed. These are cast in a grated mold, forming squares of about two pounds' weight, which are then heated nearly to redness and granulated by beating on an anvil or in a mortar. The components of silver solder vary from 4 parts silver and 1 copper for the hardest, to 2 silver and 1 brass wire. Three fourths of a part of arsenic is sometimes added to render it more fusible and impart whiteness. See ALLOY; BRAZING.

Hard'ware. A term including articles of metal for sale, such as house trimmings and furnishings, and mechanic's tools. Sometimes distinguished as *builders' hardware*, *domestic hardware*, and *tools*.

Har'dy. (*Forging.*) A *chisel* or *fuller* having a square shank for insertion into a square hole in an anvil called a *hardy-hole*.

Fig. 2400.



Calk-Forming Anvil.

The hardy-hole is sometimes occupied by a smaller anvil, fullering-tool, or calking-swage, as in the illustration, in which in a steel-faced plate is sunk a vertical groove, and the faces on each side of the groove are inclined, so as to give the proper taper to the inner sides of the calk when the horseshoe is placed within the groove.

Hare. The fibrous portion of flax and hemp, as distinguished from the *shives* or scales of bark, etc., which fall from the hare in braking.

Harl. The filament of flax. *Hare.*

Har-mon'i-ca. (*Music.*) 1. *a.* A musical instrument formed of a number of glasses which are tuned by filling them more or less with water, and are played by touching them with the dampened finger. The less the quantity of water the lower is the tone of the scale. Called *musical glasses*. The instrument is said to have been invented by a German, and was improved by Dr. Benjamin Franklin. A stringed form is ascribed to Stein, 1788.

b. Dr. Franklin's "Harmonica" consisted of a nest of hemispherical glasses, of different sizes, tuned, and arranged on a revolving spindle impelled by a treadle, the tips of the fingers being applied to the edges of the glasses to produce the tones.

Each glass has an open neck or socket in the middle. The thickness of the glass is about $\frac{1}{10}$ inch near the brim, but thicker nearer the aperture, which in the largest glasses is 1 inch deep, with an aperture $1\frac{1}{2}$ inch wide. These dimensions lessen as the glasses diminish in size, the neck of the smallest being $\frac{1}{2}$ inch thick. The largest glass is 9 inches in diameter, and the smallest 3 inches. Between these are 23 different glasses, differing from each other $\frac{1}{4}$ inch in diameter. Each glass is marked with a diamond the note for which it is intended, and is tuned by diminishing the thickness of those that are too sharp. This is done by grinding them round the neck towards the brim, the breadth of 2 or 3 inches, as may be required, frequently testing them by a well-tuned instrument. The largest glass in the in-

Digitized by Google

strument is C, a little below the ordinary compass of the human voice, and the highest is two octaves above. The glasses of the full notes are painted the seven prismatic colors, and the semitones white.

The glasses are fixed on a spindle of hard iron, 1 inch in diameter at the larger end and tapering to ¼ inch at the smallest, and each glass has a bushing of cork where it is attached to the spindle. The glasses set within each other, a space intervening between the necks of the several glasses. The spindle is mounted horizontally in a box, its ends work in brass gudgeons, and it is impelled by a treadle and band. An inch of the brim of each glass is exposed to be touched by the finger as the spindle and glasses revolve.

The instrument is played upon by a person sitting before the instrument, turning the treadle with the foot, and wetting the fingers now and then with a sponge and clean water.

The fingers should be first soaked in water, and should be perfectly free from grease. A little fine chalk may be added to the water, and will assist in producing the tremulous action of the glasses which causes the tone. Both hands may be used.

2. A small instrument of music held in the hand and blown by the breath. At the edge are a series of holes which conduct the breath to free reeds, like those of an accordeon. A *mouth-organ*.

Har-mon'i-phon. (*Music.*) A small instrument with a key-board, in which the sounds are produced by small metallic tongues, acted upon by air blown through a flexible tube.

Har-mo'ni-um. (*Music.*) A musical instrument whose tones are produced by the vibration of metallic reeds operated by keys. The bellows are worked by pedals, and the keys are arranged in one or two banks. These instruments are made with a variety of stops, and with swell and tremolo attachments. The instrument is used as an organ of small size in parlors, and in churches in the performance of sacred music.

The melodeon and parlor-organ are of this class.

The *harmonium* is substantially the same as the *æraphine* introduced by Green, and has been blessed with a variety of names derived from the Greek and other sources. Among them are *æolophon*, *æolomusicon*, *physharmonica*, *melodeon*, *symphonium*, and *poikilorgue*.

The *free* tongues of the harmonium, though used from time immemorial by the Chinese, were introduced into Europe by M. Grenié in 1810.

Har'mo-nom'e-ter. An instrument for ascertaining the harmonic relation of sounds. It often consists of a single string with movable bridges.

Har'ness. 1. (*Menage.*) The means whereby a draft animal is attached to a vehicle.

The invention is ascribed to Erichthonius of Athens, who was made a constellation after his death, under the name of Boötes, about 1487 B. C. War-chariots are believed to be much older than this. The sculptures of the Egyptian conqueror, Osymandyas, who carried his arms as far as Bactria, 2100 B. C., disprove the Greek claim. The use of harness commenced as soon as the horse was tamed to draft. The wagons that Joseph gave to his brethren to fetch his father, 1706 B. C., were probably ox-carts or wagons. The root of the Hebrew word signifies to roll around.

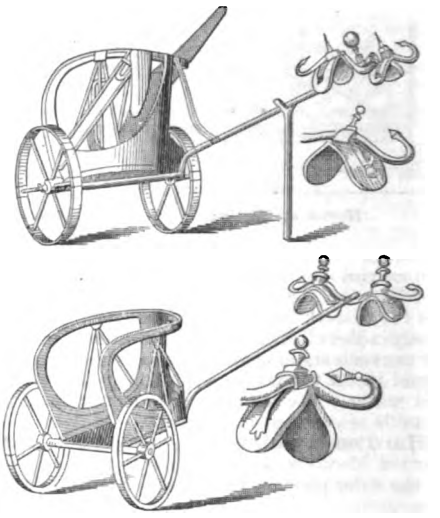
The harness shown in the sculptures of Egypt and Persepolis was of a very simple description. The horses were always hitched abreast to a tongue or pole, which was connected to a yoke. This passed over saddles which rested on the withers of the horses. The accompanying cut shows their relation and position. They were kept in position by straps around the neck and around the girth, and sometimes had a single trace on that side of the horse against the pole.

Solomon had 40,000 stalls for his chariots, 1014 B. C., and plenty of leather harness, no doubt. He bought his horses in Egypt.

While the Egyptian yoked his horses to the pole of his chariot, and gave a third horse a single trace on the side towards the chariot, still more primitive customs were adopted in other lands and at a later date.

In England and Ireland, horses were sometimes hitched to the plows by their tails, a barbarous cus-

Fig. 2401.



Egyptian Car-Saddles (from Wilkinson).

tom that existed in Ireland, as late as 1634, for an act of the Irish Parliament, 11 and 12 Car. II. c. 15, entitled an "Act against plowing by the tayle and pulling wool off living sheep," sets forth, that "Whereas there have been for a long time practiced in this country a barbarous custome of plowing, harrowing, drawing, and working with horses and other animals by the tayle, whereby the breed of animals in the kingdom is much impaired, and great cruelty perpetrated, these practices were henceforward to be considered illegal, and the offender subjected to fine and imprisonment."

"The Spaniards outwitted the French in lining their own harness with chains, so that it could not be cut." — PEPYS's *Diary*, 1661. This was on the occasion of a struggle for precedence between the Spanish and French ambassadors in London, September, 1661.

The *single-line* mode of driving horses, usual on farms and with heavy road teams throughout the West, was made very familiar to many during the late war. The government six-mule teams are driven by a man riding the near wheel-horse, and having a single line to a bridle-rein on the near leader. The bit of the off leader is connected by a *jockey-stick* to a hame-ring of the near leader, which keeps him in place. The off-wheeler is governed by the whip, foot, or an occasional touch of his rein; the whip, however, and the word of command, are relied on so far as he is concerned. The near-wheeler, being ridden, is controlled in the usual way; and

Digitized by Google

the middle span between the leaders and wheelers have no choice but to go with the others and pull when they are told to.

The *single-line* mode of driving is also used by the farmers in the Netherlands, the near horse being guided by the line and the bridles of the middle and off horse (three abreast) being connected to the near horse, "in a manner surprizing to a stranger," says Loudon.

Besides the different kinds of harness depending upon quality and mounting, other varieties are known by the names of buggy, coach, cart, or wagon, according to the vehicle, and the latter have a familiar division into *lead*, *hip-strap*, *breeching*, or *yankee*, according to the construction and arrangement. The latter is perhaps somewhat local, but is as extensive as the West, as we call it.

For a list of the tools and implements of the saddle and harness maker, and the kinds and parts of harness, see SADDLERY AND HARNESS.

For a list of the tools, machines, and various products of the leather manufacture, see LEATHER.

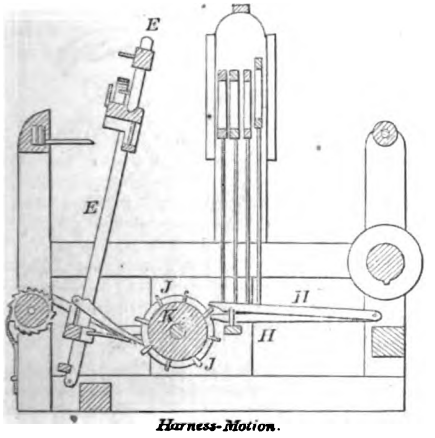
The traces of the wheel-horses in field-carriages are directly attached to the splinter-bar of the limber, no single or double trees being employed. The tongue is supported by neck-yoke and breast-chains. The traces of the leaders are directly attached to the traces of the wheel-horses, and not by means of single trees and spreader chains to the tongue.

2. (*Loom.*) The apparatus in a loom by which the sets of warp-threads are shifted alternately to form the *shed*. Each set of the warp-threads lies in the loops of knotted cords stretched in vertically reciprocating frames called *heddles*, or *healds*. These are moved by cords or straps connected to rods or levers, to which the appropriate recurrent motion is imparted. See LOOM.

The harness of a loom is termed the *mounting*; and the whole apparatus concerned in the motions of the warp-threads is the *shedding*.

The illustration shows a form of hand-loom in which the motion of the lathe *E* is the means of

Fig. 2402.



Harness-Motion.

working the harness in the order required by the twill, check, or pattern. As the lathe *E* is moved toward the treadles *H*, the lever pushes the pin *J*, with which it may be in contact, and revolves the drum *K*, operating the treadles *H*. As the lathe moves forward, the spring raises the lever into position to take hold of the next pin and again revolve the drum at the next backward movement.

Har'ness-bell. A small bell, usually of globular form and carrying a bullet, attached to some part of the harness to produce a jingling sound. A *sleigh-bell*.

Har'ness-board. (*Weaving.*) The *compass-board* of a loom, having holes through which pass the neck twines.

Har'ness-cask. (*Nautical.*) A large cask or tub with a rim cover, containing a supply of salt meat for immediate use.

Har'ness-clamp. (*Saddlery.*) A kind of vise with a pair of jaws closed by a spring, wedge, or screw, and used to hold leather while being stitched.

Har'ness-hook 1. A hook or bracket on which harness is hung.

2. A check-rein hook on the gig-saddle.

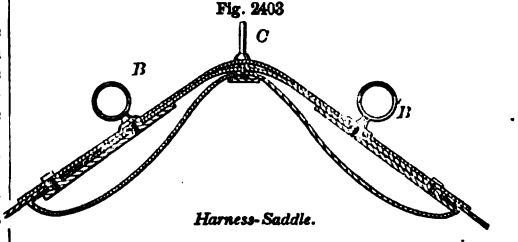
Har'ness-leath'er. A grade and quality of leather from which harness is made. It is blacked on the *grain* side.

Har'ness-pad. A lining or soft wad beneath a saddle to keep the harder portions from galling the back of the animal.

Har'ness-room. One attached to a stable, warmed by a stove, and used for putting away harness.

Har'ness-sad'dle. The part of the harness which rests across the back, and to which the girth-

Fig. 2403



Harness-Saddle.

ing portions are attached. Upon it are the terrets *B B* and check-line hook *C*, and from it proceeds the back-strap, which reaches to the crupper.

Har'ness-snap. A hook for attaching the lines (reins) to the bit-rings; the breast-strap to the hame-rings, etc. A *snap-hook*.

Harp. 1. (*Music.*) An instrument with a three-sided frame, between two of which strings of varying lengths are stretched.

Jubal, the son of Lamech the first (say about 2400 B. C.), was "the father of all such as handle the harp and the organ." His brother Jabal had great stock of cattle, and his half-brother Tubal Cain was "an instructor of every artificer in brass and iron." Quite a distinguished and industrious family. Agriculture, the mechanics, and the fine arts pursued by the sons of one man, a descendant in the fifth generation of Cain.

The harps of Egypt were numerous and various, having from 4 to 14 strings as long ago as the reign of Amosis, about 1570 B. C., 900 years before Terpander. The strings were of catgut, and the form of the frame varied according to its purpose. To be carried or played standing, sitting, or squatting.

One harp discovered in Egypt in 1823 had several remaining strings which responded to a touch, and awoke from a rest of 3,000 years.

a is an Egyptian harp from a painting at Thebes.

b from a painting at Dendera.

c one of the Bruce harpers, two of whom are shown in the original.

One of the harps has 21 strings, the other 12.

These most florid and striking of all the representations of the Egyptian harp are on the tombs of the

Egyptian Harps

kings at Thebes of the time of Rameses III., 1235 B. C.; of them Bruce says: "They overturn all the accounts hitherto given of the earliest state of music and musical instruments in the East; and are altogether, in their form, ornaments, and compass, an incontestable proof, stronger than a thousand Greek quotations, that geometry, drawing, mechanics, and music were at the greatest perfection when this instrument was made, and that the period from which we date the invention of these arts was only the beginning of the era of their restoration."

Pythagoras and his compeers derived their knowledge from this source, and the services of Terpander are probably limited to inventing a method of expressing musical sounds, and perhaps of setting poetry to music. Fame enough for one man.

The Egyptian harps are shown, resting on the ground, supported in front of the person in marching, supported on a stool, and resting on the shoulder; the latter at Eléythya.

The present scale of musical notation is ascribed to Guido Aretino, a Tuscan monk, about 1025.

"Hermes invented the harp with three strings, causing the three several sounds; the base, treble, and mean."—DIODORUS SICULUS.

"From the song, the rhythm, and the instruments, all Thracian music is supposed to be Asiatic. The Orphic ceremonies had their origin among this people" (STRABO). The instruments were the cithera, pipes, cotylæ (probably castanets or cymbals); embracing wind, stringed, and percussion instruments.

Terpander of Lesbos added three strings to the lyre; he caused

"New hymns to resound on a seven-stringed cithara."

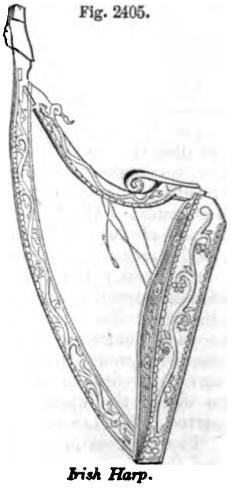
David is celebrated as a performer upon the harp, and it is said that he was a master of thirty-two other instruments. This was about 1063 B. C.

The *magadis* of the Thracians was a three-cornered harp, with twenty strings arranged in octaves. It was used among them in the time of Xenophon.

A band of 300 harpers was in the great procession of Ptolemy Philadelphus, preceding a column of 2,000 yellow bulls, with gilded horns and frontlets, crowns, necklaces, and breastplates of gold.

Egyptians, Jews, Persians, Thracians, Greeks, Romans, Saxons, Welch, Irish, all had their harps. The number and material of the strings differed, and also the shapes of the frames.

Fig. 2405.

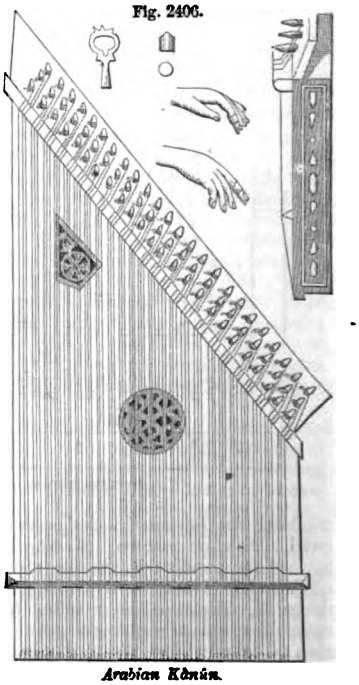


Irish Harp.

The Welsh harp was strung with gut. The Irish harp was strung with wire.

Donagh, the son of Brian Boiroimhe, a king of Ireland who was slain 1014, sought protection at Rome, carrying the harp and regalia of his father, and presented them to Pope John XVIII. in order to obtain absolution for the murder of his brother Teig. Adrian IV. urged this as a title to the kingdom in his bull, transferring it to Henry II. The harp was preserved in the Vatican, and given by Leo X. to Henry VIII. with the title "Defender of the Faith." It is needless to say how much the Pope was disappointed in his pupil. The gold crown of Brian was retained. The harp was given by Henry VIII. to the Earl of Clanricarde, and, after passing through several hands, was lodged in the College Museum, Dublin, 1782.

Fig. 2406.



Arabian Kânûn.

The modern Arabian harp, or Kânûn, is laid flat in the lap while being played. The strings are arranged in groups of three, and the sounding-board is pierced. The strings are stretched as in our pianos, and rest on a bar near the tuning-pins,

Digitized by Google

and on a bridge-piece above the sounding-board. This harp is played by the fingers, but thimbles with points are used on the two forefingers, forming an approximation to the *plectra* wherewith some of the Egyptian harps and psalteries were struck.

The prostrate harp is the original of a host of instruments played by keys; the early forms were known as the *clavichord, virginal, spinet, clavicymbal, clavicytherium,* and *harpsichord.* These grew out of various forms of stringed instruments, known as the *dulcimer, psaltery, citole lyre, cithara, cymphonia* or *cymbal, citherium,* and *harp.* See PIANO-FORTE.

The *harpsichord* immediately preceded the *piano-forte.*

In the earlier forms of these instruments the number of strings was not equal to that of the keys, but the latter brought into action devices which shortened the strings, in the manner of a guitar.

We read of an instrument in 1600 which had a key for each string, but this was unusual at that time.

Pedals were introduced 1720; double-action about 1808.

2. A concave grating in a scutching-machine, through which refuse escapes as the cotton is beaten and driven forward by the revolving beater.

3. (*Husbandry.*) A Scotch grain-sieve for removing weed-seeds from grain.

Harp'ing-i'ron. A barbed javelin. The word is derived from its capacity for clawing or grasping. A *harpoon.*

Harp'ings. (*Shipbuilding.*) *a.* The wales of the bow, of extra strength.

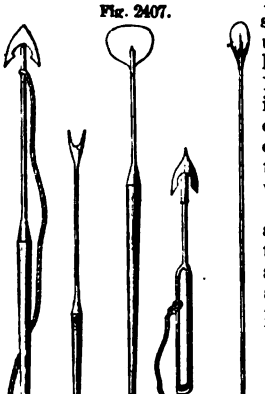
b. A ribband trimmed to the shape of and bolted to the shape of the cant bodies, to hold them together till planked.

c. Cat-harpings; frapping of the shrouds to the masts below the tops.

Har-poon'. A barbed javelin used to pierce and fasten to whales. It has a broad, flat, triangular, barbed, sharp head, and a shank about two feet long, furnishing a socket for the shaft. A line, about 70 fathoms long, is attached to the harpoon, and runs out rapidly as the struck fish dives below the surface.

The harpoon consists of the *point-head* and *shank.*

Fig. 2407.



Whaling-Implements.

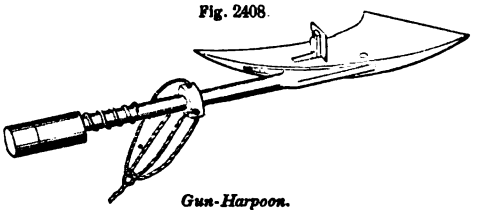
The *fore-ganger* is the section of line which unites it to the whale-line. A whale-line is 130 fathoms, and a boat is provided with several of such. It runs out over the bow, being taken over a *bollard,* which is kept wet.

The word *harpoon* is allied to the *harpago* of the Greeks, which was a grappling-iron, a drag, a flesh-hook. Specimens in bronze of the latter are in the British Museum.

In the accompanying cut are shown the ordinary whaling-implements, the hand-harpoon, pricker, blubber-spade, gun-harpoon, and lance. See BOMB-LANCE; GUN-HARPOON.

Fig. 2408 is a gun-harpoon. The rubber spring on the end of the shaft of the harpoon prevents the recoiling of the gun. A spiral spring around the shaft prevents the line from checking against the butt of the harpoon too sud-

Fig. 2408.



Gun-Harpoon.

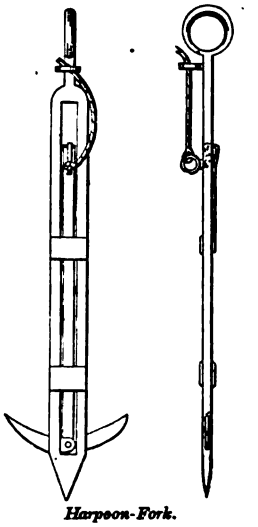
denly. A stop in the pivoted blade secures it parallel to the shaft until released by the stop, being forced down by the entrance of the blade into the whale.

The electric harpoon is fitted with two insulated conductors, connected by wires with a coil-machine kept in the boat. On the harpoon being plunged into the whale's body, electric shocks of a powerful nature are sent until the animal is prostrated.

Another plan proposed is that of firing an explosive shell into the body of the whale from a rifle, by which its vital parts would be destroyed.

Professor Christison has published an account of some experiments made in 1831 for the capture of whales by poison. The agency employed was hydrocyanic or prussic acid, inserted in glass tubes, and in weight about two ounces. A copper wire was attached to each side of the harpoon near the blade, the other end of which passed obliquely over the tube, then through an oblique hole in the shaft, and finally to a bight in the rope, where it was firmly secured. When the harpoon struck the whale, the tubes were crushed. After being struck, the whale dived, but rose in a few minutes quite dead.

Fig 2409.



Harpoon-Fork.

Har-poon'-fork. (*Agriculture.*) A form of hay-fork to be operated by tackle in lifting hay from a load to mow it away, or conversely in loading a wagon from a mow.

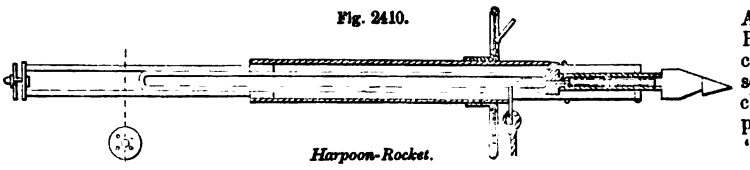
The rod being drawn up, the point of the fork is thrust into the hay, which movement depresses the rod and extends the tines, and enables the bent end of the spring to catch the top of the rod; the tines are thus held until the load is raised, when, by drawing on the cord, the spring is pressed back by the bell-crank, and the load discharged. See HAY-FORK.

Har-poon'-rock'et. A bomb-lance for killing whales. That shown has an explosive shell at its head, and is propelled by a rocket-charge after being fired from a gun. The hinged barbs are secured to the breech-piece in the tube, and the line connected by a looped shank.

Harp'si-chord. (*Music.*) An obsolete stringed instrument resembling a harp laid prostrate, the strings being played by quills operated by keys like those of a *piano-forte.*

Digitized by Google

Fig. 2410.



Harpoon-Rocket.

The harpsichord is believed to have been first made by Hans Rucken, in Germany, about 1510. Used in public festivals in Italy, 1522. Improved by Vincentino, 1555. Vertical form invented by Rigoli of Florence, 1620.

Pepys, in his Diary (1661), speaks of the "harpsichon" at Captain Allen's house, where he saw his dear "Mrs. Rebecca."

The *spinet* was a similar instrument with one wire for each note, and, like the harpsichord, was played with quills on jacks, operated by keys.

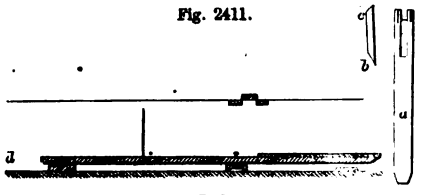
The *clavicytherium* may be considered the original of the whole train of stringed instruments whose strings were mechanically vibrated. See PIANO-FORTE.

The harpsichord introduced two strings to a note, and preceded the piano, from which it differed specially in the mode of vibrating the strings.

It consisted of a harp whose wire strings were touched by quills operated by keys. Each quill was a plectrum, and was a substitute for the human finger, the musical effect being similar to that of the harp, as it was intended to be. The instrument might be called a horizontal harp in a frame, the strings being touched by quills set in motion by the fingers applied to keys on a key-board. We read of it first among the Provençals, the Troubadours who twanged ecstatically.

The *spinet* was so called because its quills or plectra resembled thorns. (*Spina*, Latin, a thorn.) The

Fig. 2411.



Jack.

instrument was invented by the Italians, and was like the harpsichord, but smaller.

The quill was attached to an upright piece called a *jack*, *a*, whose lower end rested on the key which raised it, causing the quill *c* to bend and slip past the string, where it remained so long as the finger was pressed upon the key. In returning, the swiveled piece to which the quill was attached gave way to allow the quill to pass the string, and the swiveled tongue was restored by a bristle *b*, which acted as a delicate spring. A small piece of cloth on top of the jack rested on the wire and acted as a damper.

Whether the modes of *twanging* the strings by a plectrum or quill, in imitation of the action of a harpist, preceded all the devices for *striking* the string, it is not easy now to determine; but the latter mode, which appears to have originated in the *clavichord*, has entirely superseded the quill.

An early and obsolete predecessor of the piano was the *virginal*, which had *keys* and jacks, but only one string to a note. See VIRGINAL.

It is mentioned by Shakespeare, —

"Still virginaling
Upon his palm" *Winter's Tale.*

And also by Gabriel Platte, who, in the succeeding century, describes a dibbling machine as formed of iron pins, —

"Made to play up and down like virginal jacks."

The *clavichord*, *d*, is said to have consisted of a range of brass wires placed above the keys, which latter had wires on the rear ends, acting as hammers upon the strings when the keys were struck. A muffling-piece on the string limited the portion involved in the vibration and acted as a damper.

One mode of striking the wires in this instrument was by a leathern button on the top of a piece of strong wire fixed in the farther end of the finger key. This little device was the simplest possible form of a stringed instrument played by means of keys. The striking part was called a *jack*. It was a favorite instrument more than a century before the invention of the harpsichord, and must be considered the original of the piano-forte.

The pins formed wrest-pins for the strings, which vibrated only while the key was held down, and the place at which the pin struck the string determined the length concerned in the vibration. A damper fixed behind the string acted upon it when the pin quitted the string, the key, in fact, forming one of two bridges, between which the strings vibrated.

The instrument was an important one for several hundred years; the favorite of Bach and of Mozart.

The *hammer-harpsichord* is referred to in the "Giornale d' Italia," 1711, and was the first *piano-forte*, though the name was not given till about fifty years afterwards. It was the invention of Cristofori of Florence; the improvement consisting mainly in pivoted hammers, which were struck by jacks on the keys, and retired immediately from the strings. See PIANO-FORTE.

The pedals were invented by Loeschman.

The *double-harpsichord* had two sets of keys and strings in a set. One key of one set struck two keys in unison; while one key of the other set struck a string tuned an octave higher. A farther change removed one bank of keys, and the three strings were tuned in unison.

Har'row. (*Husbandry.*) The harrow is a large rake, being a frame with teeth drawn over the ground to level it, stir the soil, destroy weeds, or cover seed.

It is a frame, usually of wood, and has downwardly projecting teeth which penetrate the soil. The shapes of the frame are various. The teeth are usually of square bar-iron, sharpened to a point, maintaining the square form. They are set in the harrow-frame so as to move in a direction parallel to their diagonals.

As stated under the appropriate heading, the cultivator is an improved harrow; handles being added to increase its manageability; and colters or shares substituted for straight teeth, thus increasing its efficiency.

Harrows are made with the various modifications mentioned, and others might be cited, but still they are called harrows by their makers, setting classification at defiance. These hybrids are useful and efficient tools, many of them, but it is not easy to give them a "local habitation" or "a name" in a classified digest of machines.

Two notices of the harrow are found in the Bible. In Job is the inquiry, "Will he [the unicorn] harrow the valleys after thee?"

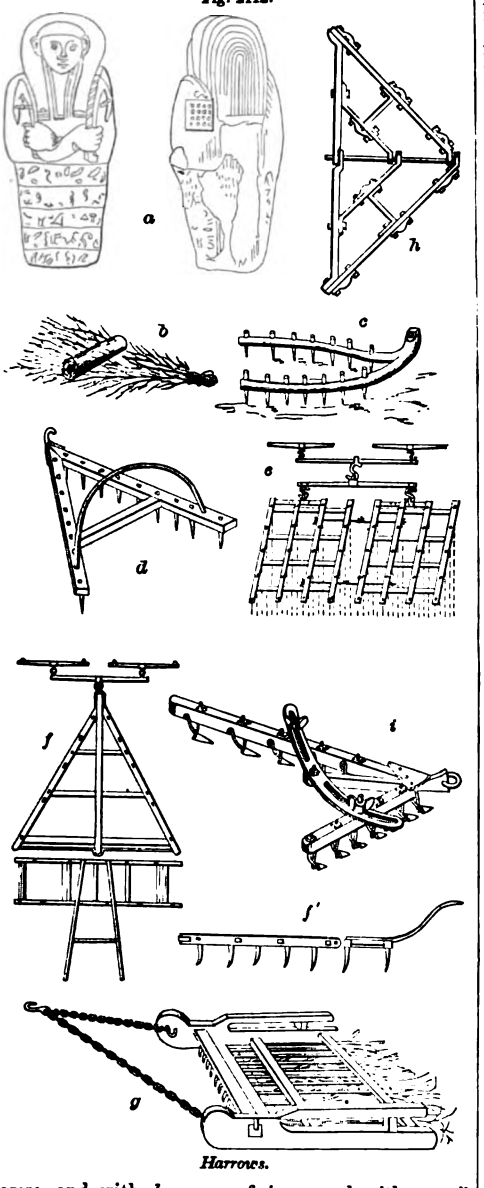
The word is said by some Hebraists to be a mis-

Digitized by Google

nomer; a seed-covering tool is referred to, drawn by animal power, and may have been a plow. Their thrashing drag would have made a tolerable harrow. It was a frame of boards, studded with spikes. See THRASHING.

The other reference to the harrow occurs in the account of the cruelty practiced by David upon the men of Rabbah, 1033 B. C.: "He cut them with

Fig. 2412.



Harrows.

saws, and with *harrows* of iron, and with *axes*." (1 Chron. xx. 3.) The parallel passage in 2 Samuel xii. 31 states that "he put them under saws and harrows," etc. Adam Clarke disputes the rendering, and declares that the original means he made slaves of them, putting them to work with saws, harrows, and axes. *Quien sabe.*

Although the images of Osiris are represented with a plow in each hand (*a*, Fig. 2412), and something like a harrow hanging by a cord over the left shoulder, still the harrow does not appear to have been in ordinary use in ancient Egypt. In the elaborate sepulchral paintings, the various operations of husbandry are carefully depicted, and these show that the clods were broken by hoes, and the seed was covered by hoes, plows, the tramping of men or animals, and perhaps by dragging bushes over the surface. Being sown on the mud left by the retiring Nile, the seed needed little attention and soon germinated. The amount of mud left by the Nile raises the cultivated land about six inches in a century at Elephanta.

An inscription of the age of the Emperor Antoninus on the pedestal of the vocal Memnon shows that the soil at Thebes has risen seven feet in 1,700 years, say five inches to the century. An excavation at the foot of one of the colossal sphinxes at Karnak shows a deposit of eighteen feet above the layer of spawls and rubbish forming the foundation. Beneath this is an alluvial deposit of unknown depth. The rise of eighteen feet indicates a period of 2,250 years B. C. for the erection of that sphinx. The elevation of the land by the sediment of the inundation decreases southwardly. The periodical rise commences about June 1, it increases for three months, remains stationary about twelve days, and then subsides. The rise is greatest in Upper Egypt, and less towards the mouth. Thirty-six feet rise is a "good rise" at Thebes, twenty-five feet at Cairo. The rise at the Damietta and Rosetta mouths may be about four feet. The land is gradually encroaching on the desert in most places; buildings and monuments originally erected on the barren land outside of cultivation have now a depth of many feet of soil around their bases. Many of the sites of antiquity are now buried. (See Wilkinson.) The amount of land inundated by the Nile is about 5,626 square miles (average). This does not include the river and lakes.

Harrows bore the same part in the operations of husbandry in the time of Pliny (A. D. 79) that they do now. "After the seed is put in the ground, harrows with long teeth are drawn over it."

The common harrow of the Romans was a hurdle, but they also used harrows made of planks studded with iron spikes.

The harrow is represented in the tapestry of Bayeaux, A. D. 1066, and is mentioned by Googe, in his "Heresbachius," A. D. 1578.

An act of the Irish Parliament was passed in 1634, forbidding harnessing horses by the "tayles" to harrows. See notice under HARNESS, p. 1062.

Harrows are made of various forms, and if we reject the harrow, if such it be, on the shoulder of Osiris (*a*), we may suppose it to have been originally a bundle of bushes (*b*) tied together at the butts, and thus dragged over the field. A log on the brush — as we of the West term it — would flatten as well as weight it, and would add to its efficiency. The bush-harrow is very efficient in covering timothy, clover, etc.

Directions for the construction of a harrow are given by an English agricultural writer in 1668, as follows: —

"Get a pretty big white-thorn tree, and make sure that it be wonderful thick, bushy, and rough grown."

In some parts of the north of Europe, the spiky limbs of fir-trees are bound together, and the spurs of the limbs make a reasonably fair substitute for the tines of a harrow.

In another form, the bush-harrow *g* is used under conditions where the teeth of an ordinary harrow

Digitized by Google

would penetrate too far, as in covering grass-seed. The bushes are cut and so disposed in a frame as to present a moderately level surface of limbs, which, as they pass over the land, reduce inequalities and cover the seed as deep as desirable. The object, of course, in putting land down to grass is to obtain a good level surface over which to mow.

The thrashing-sled of the Egyptians and Syrians, the tribulum of the Romans, may have been used for dragging over the ground to cover seed, but it does not so appear. As stated, the harrow in the time of Pliny had long iron teeth.

A convenient limb of a tree has often furnished a ready frame for a harrow, *c*, which is attached by a clevis to the double tree of the team or the chain of the oxen. In still earlier periods it was hauled by a withe, a grape-vine, or a rawhide rope.

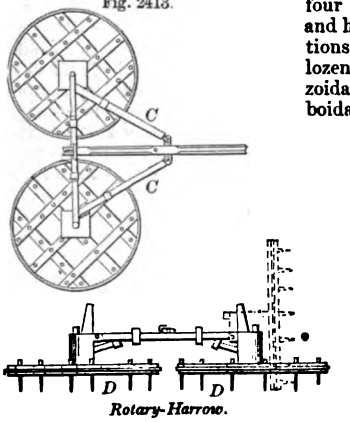
From this the step is easy to the letter "A" harrow *d*, which is a very familiar form in new countries. It is very handy in ground from which stumps have not been eradicated. It is easily lifted by the corner or by the bow.

The usual form of the British harrow is called the Berwickshire pattern, *e*. It consists of two parts joined together by iron rods, having hasps and hooks. Each part consists of four bars of wood connected by cross-bars mortised through them. The former of these are made of 2½ by 3 inch scantling, and the latter of 2 by 1 inch stuff. The bars meet at a certain angle, so that the figure formed is a rhomb, and the teeth are inserted into the bars at equal distances from each other. This obliquity is such that perpendiculars from each of the teeth, falling upon a line drawn at right angles to the line of the harrow's motion, shall divide the space between each bar into equal parts, so that the lines marked by the teeth in the soil shall be parallel and equidistant.

h is a double-harrow with folding sections. *f f'* is another form of double-harrow consisting of a triangular frame to which the team is hitched, and a square frame hinged to the former, so as to be brought into effective position or be laid over the other when not required. The rear portion has handles, and its teeth split the balks between the furrows left by the teeth of the preceding harrow. *f* is a top view, *f'* a side view.

Double-harrows are made in many other forms, two, three, or four leaved, and having sections square, lozenge, trapezoidal, rhomboidal, or triangular. Specimens of each would be given did space permit.

Fig. 2413.



Rotary-Harrow.

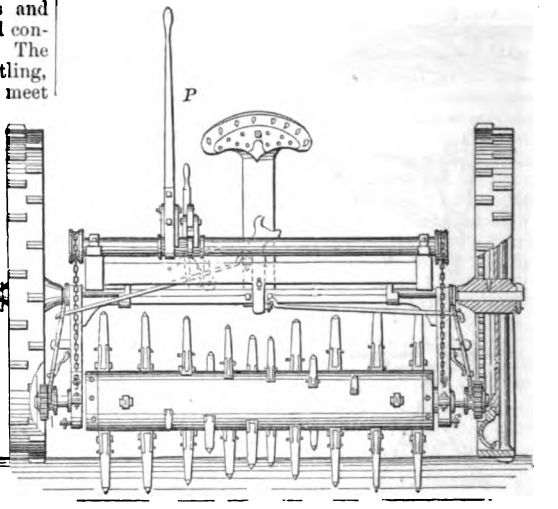
The harrow *i* is for grassy or weedy lands, and has teeth of cultivator form, presenting V-shaped blades which cut at a distance below the surface, say two or three inches. This in many cases is much more effectual than the mere jagged tearing action of simple spikes.

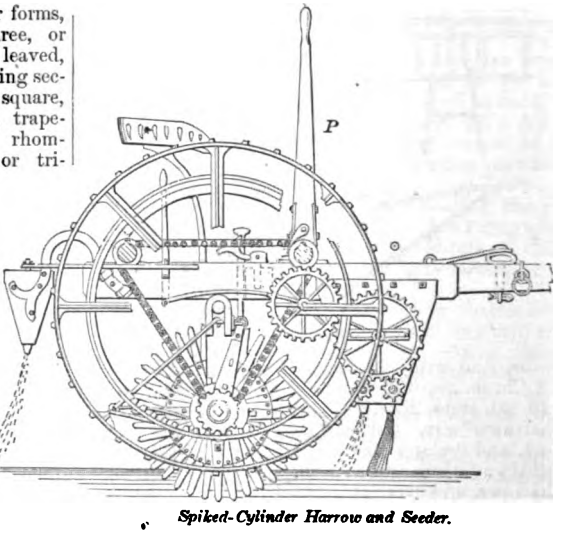
Another kind of harrow is drawn in the rear of and partly suspended from an axle and pair of wheels. This implement has also its proper place in some kinds of soil and modes of tillage.

Rotary harrows are made in many forms, and may have one, two, or more sections which lie flatly upon the ground, as in Fig. 2413. Each section *D* is eccentrically journaled by an upright axis to the frame *C*, and as a consequence of the eccentricity the sections rotate as the harrow advances over the ground. As a greater number of spikes are presented on one side of the axis of rotation than on the other, their hold on the ground is greater, and the lighter side is obliged to rotate forwardly.

The flexible spiked-chain harrow used in England is made of wrought-iron links, so shaped and com-

Fig. 2414.





Spiked-Cylinder Harrow and Seeder.

Digitized by Google

bined as to keep the harrow stretched, while a certain number of the teeth, at regular intervals, have dependent spikes.

The spiked-cylinder harrow, known in England as the Norwegian harrow, has three sets of rowels placed in gangs upon an iron axle. It is used for reducing the land to a fine tilth for the reception of seed, which it does to a depth of three or four inches in soil which is in suitable preliminary order. No amount of drawing spiked tools over a wet clay bed will make friable soil, and the use of this tool, as well as of crushing-rollers, is a thing to be done in the right time and place. Fig. 2414 shows an American form of this tool, which is intended for sowing fertilizers, grain, and grass-seed, and harrowing in the same. A portion of one driving-wheel is broken away in the upper view, in order to expose the internal cog-gear by which the spiked cylinder is rotated, as it does not depend upon its contact with the ground for its rotation. The feeding devices for seed and fertilizer are driven by chain-band connection with a wheel on the spiked drum. The spiked cylinder may be raised from the ground by the lever *P*, or adjusted as to depth of penetration.

Har'vest-er. (*Agriculture.*) A machine for cutting grain or grass. See MOWER; REAPER.

Hassock-Filler.

the radiated heat around the joint which is being roasted.

Hat. 1. A head-covering with a crown, sides, and continuous brim. Made of cloth, felt, straw, silk, splints, grass, etc.

Felt hats are as old as Homer. The Greeks made them in various forms; skull-caps, conical, truncated, narrow or broad brimmed (*petasus*). The Phrygian bonnet was an elevated cap without a brim, the apex turned over in front. This form is

Digitized by Google

very old, and indicates an inhabitant of Asia Minor. It is known now as the *cap* of liberty. In Rome, the ceremony of manumission of a slave, the head was shaved and a *cap* presented as an emblem of freedom. An ancient figure of Liberty, of the time of Antoninus Pius, A. D. 145, holds the cap in the right hand.

We even find them with brim and no crown. Tied before or behind, — we thought this was quite modern. A broad-brimmed hat is shown in the sculptures of Karnak.

Herodotus refers to the soft hats of the Persians. They wore round-top caps without peaks, somewhat resembling the modern *fez*. Hats encircled with plumes were the head-dress of the Lycian contingent in the army of Xerxes.

Herodotus said that the skulls of the bareheaded Egyptians were so baked that they would hardly decay, and were, in this respect, very different from the Persians, who protected their heads and kept them so soft that they soon rotted. He observed it, he says, on an old field of battle in Egypt; the former were as hard as a brick, and the latter decayed.

The broad-brim hat (*causia*) was worn by the Macedonian kings. It is said by Smith (Dictionary of Greek and Roman Antiquities) to have been made of felt. It is shown on a medal of Alexander I. of Macedon. It was adopted by the Romans, especially Caracalla.

In the accompanying cut are shown some of the forms which the ancient felt hat assumed. The *pileus* (Latin) was the common felt *cap*, the *fess* of the modern Greeks, the *fez* of the Turks. The *petasus* (Greek) was a *hat;* it had a brim; its name, in fact, comes from a word whose root meaning is extension, dilation.

a is from a sepulchral bas-relief in Bœotia.

b is a fisherman's cap, from a statue in the Townley collection, British Museum.

c is a coin of Bruttium, South Italy; the figures are Castor and Pollux. With us, *castor* means a *hat*, from the beaver (castor, from a Sanscrit word meaning *musk*), which supplies the best material.

d is a head of Dædalus, from a bas-relief in the Villa Borghese collection. This form is still worn by the shepherd boys in Asia Minor.

e is a head of Ulysses, from an ancient lamp. It represents him as tied to the mast while he listens to the songs of the sirens.

f is the modern Greek peasant's cap, introduced for comparison.

g is from a parian marble bust of Paris, wearing the Phrygian cap, and now in the Glyptothek, Munich.

h is from a coin of the Emperor Verus, now in the British Museum, and representing *Armenia capta*. The captive wears a *plug* hat.

i represents Dacia in mourning, with a pudding-crown hat on. It is the obverse of one of Trajan's coins.

j is from a coin of Antoninus Pius, and represents the goddess of liberty.

k is from a statue of the sleeping Endymion in the Townley collection of the British Museum.

q, from a vase of Sir W. Hamilton's.

r is from an ancient marble bust.

s t are from coins of ancient Italy, and representing heads of Mercury.

In the thirteenth century, Pope Innocent IV. allowed the cardinals the use of scarlet cloth hats.

Fig. 2419.

Ancient Hats.

The introduction of felt hats is credited to a Swiss, in Paris, in 1410, and in 1440 it is said to have become a common article of wear for travelers.

Digitized by Google

In 1449, Charles VII. made his triumphal entry into Rouen, wearing a felt hat lined with red velvet and surmounted with a fine plume of feathers. This set the fashion, and hats soon superseded the old chaperons and hoods.

Chaucer, who wrote during the latter part of the fourteenth century, represents the merchant as wearing a Flanders beaver hat. This may antedate our Swiss friend mentioned above.

The hats referred to in the reign of Richard II. (1385) were probably of cloth.

Felt hats are stated by one authority to have been first made in England in 1470; and by another authority (Stow) to have been first made there, by Spaniards, in 1510. Before this time the people, both men and women, wore close woolen caps; originally of cloth and afterwards knit. Knitting is quite a modern art.

Two centuries since, hats were customarily worn indoors.

"Home to bed; having got a strange cold in my head, by flinging off my hat at a dinner, and sitting with the wind in my neck." — PEPYS'S *Diary*, September 22, 1664.

"Home to supper, having a great cold, got on Sunday last, by sitting too long with my head bare, for Mercer [his wife's maid] to comb [his hair?] and wash my ears." —*Ibid.*, January 25, 1664.

"This day Mr. Holden sent me a bever, which cost me £4 5*s*." — *Ibid.*, 1641.

In Lord Clarendon's essay on the decay of respect paid to age, he says that in his younger days he never kept on his hat before those older than himself, *except at dinner*.

Hats, besides those of straw and similar material, are made of fur, principally that of the Russian hare or coney, mixed with a small proportion of wool or cotton.

There is a legend that the process of felting was accidentally discovered by St. Clement, who, having put some rabbits' fur in his shoes to protect his feet during a long journey, found at its conclusion that the fur had become compacted into a homogeneous mass.

The use of the fur of the beaver, which certainly dates back prior to 1585, threatens now to become obsolete, it being superseded to so great an extent by the imitation made by covering a body with silk plush.

In any process of making felt or fur body hats, the first operation is weighing out a sufficient quantity of the material to make a single hat-body.

In the hand process, the fur is bowed by being placed in a heap over a table above which is suspended the *bow*, much resembling a fiddle-bow, though having but one string which is vibrated by the workman striking it with his thumb until the hairs are brought into a light even layer. The wool is then treated in a similar way with a larger bow, and the two layers of fur and wool are, by means of a light wicker frame adapted to receive the material, placed one over the other and again bowed, when the mass is compressed by the wicker frame, and afterward by an oil-cloth pressed upon it by the hands until the fibers have become sufficiently united to bear handling.

A triangular piece of brown paper is then placed above it, over which its edges are folded, and the whole is wrapped up in a damp cloth and manipulated until the fibers have become thoroughly intertwined and the body is brought into a triangular form. This is called *basoning*.

In the next process, called *planking*, the body is alternately immersed in a kettle of very dilute sulphuric acid, to which beer-grounds or wine-lees are added, and then worked upon an inclined plane at the side of the kettle until it is shrunk to half its former size and much increased in thickness, the operation being completed by the aid of a rolling-pin which smooths and compacts the felt. The body is then dried in a stove, and sized with a brush dipped in shellac dissolved in alcohol, and again dried; any superfluous sizing is removed by dipping in an alkaline solution and scraping. Beaver fur is applied to the exterior by being mixed with fine cotton, and the two are felted, in manner similar to that described, into a thin sheet, which is affixed to the exterior of the body by manipulating it in the boiler and on the plank; in this process the cotton separates. The body is yet of a conical shape, and is partially brought into proper form by hand, and then stretched upon a cylindrical block, after which it is dyed by boiling in a solution of copperas, verdigris, gall-nuts, and logwood in water. It is now drained, dried, and removed from the block, and *finished* by placing over a jet of steam which softens it, when the brim is turned up, the stiffening of the crown inserted, placed upon a block, the nap smoothed, and a glossy surface imparted by means of warm and damp hair-brushes and a plush-brush called a *velours* (sometimes *lewer* or *lure*), finishing with a hot iron. The trimmings and lining are next sewed in, and the hat is finally warmed and such slight variation of shape imparted as the style requires.

In the present mode of making felt hats, after being *carroted* by treatment with a solution of mercury and nitric acid, in order to render the felting easier, the fur, when dry, is removed from the skin and assorted, according to quality, into back, belly, and side, the latter being the finest. These are mixed as may be required, according to the quality of the hat, and farther mixed in the proportion of 4 to 5 ounces, that being the quantity required for a hat body, with from ¼ to ½ ounce of fine carded cotton. This mixture is placed in a box above a toothed picker, revolving with great velocity, which seizes the material and conveys it on an endless belt to another picker. The agitation caused by the current of air from these assists in intermingling the ingredients.

The *stock*, as it is now termed, is next passed through a series of toothed rollers, where coarse materials and dirt fall into trays beneath, while the finer portions are forced out at the farther extremity of the machine. The stock, which is now said to be *blown*, is next placed on the feeding-apron of the *forming-machine*, in quantities just sufficient for one hat-body. Here it is drawn in between two horizontal, felt-covered feed-rollers, and seized by a cylinder provided with several longitudinal rows of stiff brushes, and making about 3,000 revolutions per minute. By this a current of air is generated, which scatters the stock and blows it out through a vertical slot at the top of the machine against a revolving copper *cone* having a great number of perforations, and partially exhausted of air by a rapidly revolving fan. When the stock from the first machine is thus all withdrawn and compressed against the side of the *cone*, a wet cloth is placed over it; a metallic cover is slipped on over this, and the whole transferred to a tank of hot water. The *mat* is next removed from the cone, small portions of stock added to strengthen any thin spots which may be detected, and it is rolled and worked in a piece of blanket. After a little manipulation, it is ready for the process of felting, which is done by experienced workmen, by constant rolling and dipping in hot

Digitized by Google

water for several hours, for the purpose of farther thickening and fulling it; or, in other words, felting the fur and reducing the large cone to the proper dimensions for making a hat. After being properly sized or felted, it is passed to the shaving-room, where the outer surface is shaved with a sharp knife by a skilled workman, to remove whatever hair may yet remain in the fur. It is then returned to the kettle for a second sizing, to farther close up and strengthen the felt. After the farther operations of being stiffened, cleaned, blocked, colored, shaped, and pounced, the body is ready for the finishing process.

The great improvement of the perforated exhausted cone, with its attendant slotted blowing cylinder, is due to H. A. Wells, by whom it was patented April 25, 1846. Williams, in England, had previously employed a partially exhausted cone in connection with a carding-machine for making hat-bodies from tow or waste silk. See BLOWING-MACHINE, p. 307.

In this country, fur, mixed with a little Sea-Island cotton, is generally employed. The forming and sizing of the body are done in a way precisely similar to that of felt hats, but a much less quantity of stock, from 1 to 1¼ ounces, is used.

After sizing, it is dipped into a solution of shellac and alcohol, drawn over a block and the brim flattened. A thick stiffening is placed in the crown and on the brim, and the body again blocked, slightly moistened, and ironed into shape. The brim is ironed on the brim-board, sand-papered smooth, again ironed and coated with a sizing of fine glue.

After this two coats of shellac varnish are applied and the body is ready to receive its silk plush covering. The plush for this purpose is imported from France and Germany, the former of superior quality.

The material is cut into two pieces which form the upper and under surfaces of the brim, and other two which constitute the body and crown. The under brim in one circular piece is first put on, and afterwards the upper brim, sewed to the crown and side piece; the whole forming a sort of bag, which is drawn over the body. The operation of sewing requires great neatness, to conceal the seam, and neatness is also required to conceal the joint where the two ends of the piece forming the side unite. This is effected by cutting off the overlapping part very exactly at the joint and brushing the nap over it; the application of a hot iron unites the plush to the body. The hat-band conceals the junction of body and upper brim, and the binding that of the upper and lower brim pieces.

The hat is finished by rubbing with small wire hand-cards and stiff brushes, after damping with a sponge, and afterwards ironing it. This straightens and lays the nap, a mixture of camphor and alcohol is applied to soften any adhering dirt, and the hat is then placed in the *luring*-machine, — an apparatus similar to a lathe, — in which the hat on its block is caused to revolve against pads of stiff woolen plush; this removes all dirt and water stains. The final gloss is imparted with the hot iron, after which it is trimmed. From the hands of the finisher the hat passes to the trimmers and curler, where the finishing touch is given and the brims molded into the shape, as the style and fashion may dictate, bringing out the Hogarth lines of beauty in their curves and curls, and adapting them to the taste of the correctly dressed gentleman of the day.

Two kinds of bodies are employed for silk hats. One consists of stiffened muslin, and the other of felt or fur.

The muslin, or, as it is termed, the gossamer body, is said to be the lightest and most durable of the two kinds used, and is rapidly superseding the fur or felt body for general wear.

Silk-hat making is known to those connected with the trade as an art, and was styled by them in olden times, "the art and mystery of hat-making."

The parts of a hat are as follows: —

a, body or crown.
b c, brim.
b, upper brim.
c, under brim.
d, rim.
The banding-point, or break of the band, is at the junction of the brim and crown.
f, side crown.
g, square. *h*, tip.

A cap differs from a hat in the shape of its brim, which projects from one side only, and is called a *fore-piece* or *visor*. A bonnet differs from a cap in the angle at which the brim projects from the body.

Fur-hat.
Leather-hat.
Paper-hat.
Silk-hat.
Spring-brim hat.
Straw-hat.

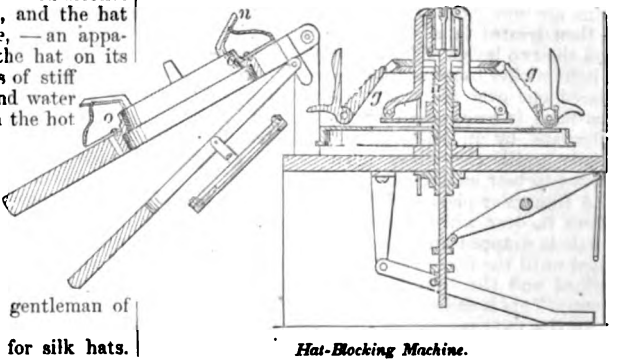
Collapsible hats, for opera or traveling, are made with springs or of springy material. See OPERA-HAT.

Panama hats are made of the leaves of the pandamus or seren pine (*Carludovica palmata*). These are gathered before they unfold, the ribs and coarser veins are removed, and the rest, without being separated from the base of the leaf, is reduced to shreds. After having been put in the sun for a day, and tied into a knot, the straw is immersed in boiling water until it becomes white. It is then hung up in a shady place, and subsequently bleached for two or three days, after which the straw is ready for use. The plaiting of the straw commences at the crown and finishes at the brim, and is a very troublesome operation. The hats are made on a block placed on the knees, and require to be constantly pressed with the breast. The coarser hat is usually finished in two or three days, but the finest often requires as many months.

2. (*Tanning.*) The stratum of bark on the top of a pile of hides and interposed bark, filling a tan-pit.

3. (*Metallurgy.*) A depression in the tunnel-head of a smelting-furnace to detain the gases.

Fig. 2421.



Hat-Blocking Machine.

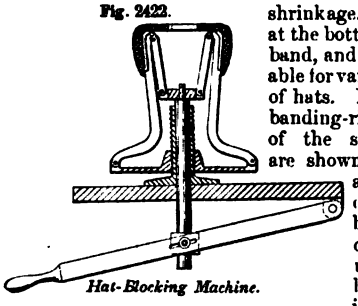
Digitized by Google

Hat-block. A form upon which the hat is finished. It is usually made of five pieces, four outside segments and a square central or key-block.

In finishing the exterior, a *spinner* is used as a stand, being simply a flat oval table, the face of which corresponds to the curve of the brim. It is removed when the under brim is to be worked.

Hat-block'ing Ma-chine'. A machine for blocking hats, stretching out the crown by means of expansible framework, and stretching out the brim by clamps, which take hold of the brim, and are then raised from an inclined to a horizontal position. The expansible framework is raised and lowered by a screw stem, so as to adjust it to varying depths of hats. The ring serves several purposes, giving pressure to the clamps by means of springs, and forming a point of attachment for the inclined projections for giving the edge of the brim an extra stretch to overcome the shrinkage. The rim *o* at the bottom *breaks* the band, and is changeable for varying sizes of hats. Fig. 2421, the banding-ring and a part of the stretching-arm are shown as laid over away from the cone; it is brought into operation upon the hat-body by swinging over, bringing the stretchers *n n* between the part *g g* and the banding-ring *o*, upon the band of the hat.

Fig. 2422.

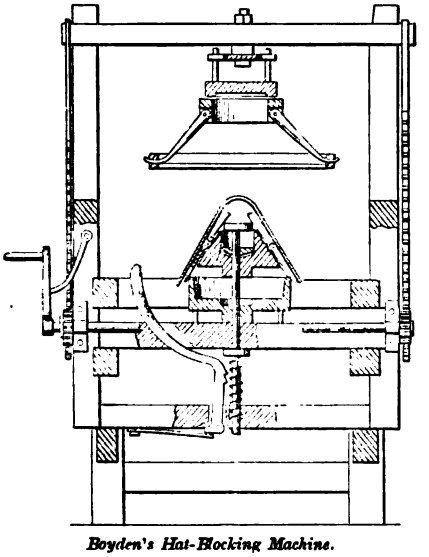


Hat-Blocking Machine.

Fig. 2422 shows the rubber over the crown stretchers to prevent undue corrugating of the body.

In Fig. 2423 the *cone* to form the body is placed upon the block *E*, which has two circumferential series of slanting ribs above it. When the carriage

Fig. 2423.



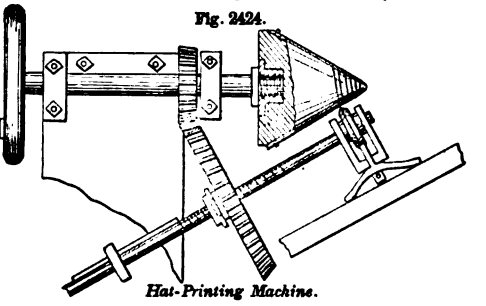
Boyden's Hat-Blocking Machine.

is raised so as to bring the cone within the hollow former above, the piston *D* expands the upper series of radial arms, distending the crown, which is thereby pressed against the sides of the block *T T*, and flattened against the crown-piece *H*; the crown and sides are then blocked. The brim is distended by the rising of the ring *L* against the inside edges of the lower and outer series of hinged arms, which are thus pressed against the under side of the brim and press the latter against and between the arms *V* of the former above.

Hat-bod'y. The entire body in an unfinished state, as the *cone* from a forming-machine, or the *shell* or *carcass* upon which plush is attached to make a silk hat; or the beaver hat before napping; or a cloth hat before stiffening.

Hat-bod'y Print'er. A machine fo printing a pattern on the exterior of a hat-body, to produce an ornamental effect or imitate a fabric. In the example, the block having the pounced hat-body thereon

Fig. 2424.



Hat-Printing Machine.

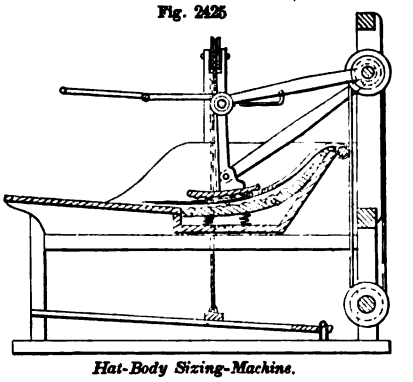
is screwed upon the end of a shaft, which is rotated in conjunction with a printing-roller, which may have more or less rapid feed given to it.

Hat-bod'y Siz'ing-ma-chine'. Sizing is a term synonymous with *hat-shrinking* and *hat-planking*. For hand process see HATTER'S BATTERY.

An operation for shrinking or reducing the hat-body to the proper size and form for making the finished hat. The apparatus consists of an elastic bed in a trough containing hot water, and a semicircular rocker, by which a kneading operation is performed on the body.

The elastic support of the corrugated bed sustains the lower end of the latter above the surface of the

Fig. 2425.



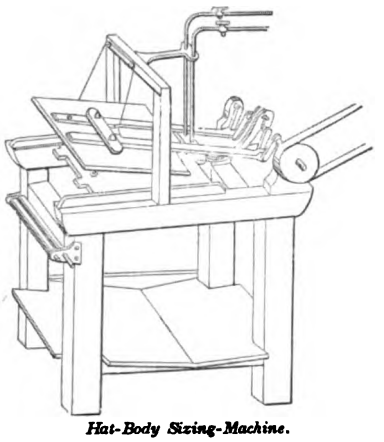
Hat-Body Sizing-Machine.

liquid, so that the roll of hats may be adjusted upon the bed without exposing the hands to the hot water. The handle, pivotal shaft, and impelling springs enable the machine to be operated by hand.

In Fig. 2426, the table has a simple horizontal reciprocation, and the platen an oscillating as well as a reciprocating motion, being rigidly attached to the pitmans. Jets of hot water or steam may be applied to the *bat* from pipes which end in a finely perforated box.

Digitized by Google

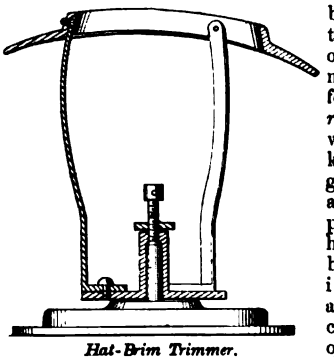
Fig. 2426.



Hat-Body Sizing-Machine.

Hat-brim Trim'mer. A pattern which determines the point at which the brim is to be trimmed. The operation is commonly performed by a *rounding-jack*, which is a curved knife carrying a gage which bears against the band while the hat is upon the block, and, being moved around the body, cuts the brim of an equal width all round.

Fig. 2427.



Hat-Brim Trimmer.

Hat-brush. A soft, drawn brush, of horse or goat's hair.

Hat-brush'ing Ma-chine'. A machine in which brushes are used to equalize and polish the nap, pile, or exterior fibrous matter forming the surfaces of hats. They sometimes rotate in contact with the body, or it is rotated while they are held in contact with it. After the forming operation, the brushing-machine removes the dust or liberated fiber.

Hatch. 1. A stop-plank falling in vertical grooves in a frame, and supporting a head of water in a weir. A *sluice*-gate. A *flood*-gate.

2. A grated weir for a fish-trap.

3. A breast-high or half door.

4. A shutter to cover a hatchway, or scuttle, in a ship's deck or warehouse floor.

5. A hatchway or opening in a deck or floor.

6. An opening into a mine.

Hatch-bar. (*Nautical.*) The bars by which the hatches are fastened down.

Hatch'el. (*Fiber.*) An instrument for cleansing flax or hemp from the *hards*. It consists of a number of teeth set in a board, upon which the hank of fiber is thrown and dragged through, so as to comb it straight and remove the coarser portions. A *hackle*.

Hatch'et. (*Carpentry.*) A one-handed chopping-tool.

Hatchets of the stone age have been found with eyes for the reception of the helve. No such perforation is found in any bronze axe or hatchet of the immense period during which the cutting tools were formed of this metal. Bronze was always cast, and it seems wonderful that no one thought of casting it with an eye. Natural holes in stones were utilized for eyes; two flint hatchets in the museum of Copenhagen are examples.

The early history of our race is written in the tools of stone, bone, and bronze. A few leaves from the chapters to be found in all our museums are transferred to these pages.

a is a copper celt from Waterford, Ireland, resembling in shape the earlier stone tools, such as axes, adzes, chisels, hoes, for the chase, war, carpentry, and agriculture.

b is a winged celt from Ireland, *c* a socketed celt from the same country.

d e f show the modes in which the celts *a b c* were stocked.

Fig. 2428.

Celts and Hatchets.

These celts vary in size from an inch to a foot in length. *g* is a stone celt.

h is a celt-mold from Ireland.

i is a decorated bronze celt from Ireland.

k l m are Danish celts of bronze.

n is a stone axe from Ireland.

o, a stone hatchet found in county Monaghan, Ireland, yet mounted in a pine handle 13½ inches long. Almost none of these weapons are found with holes for the handles. See AXE.

p is an ancient stone hatchet found at the streamtin works, Morbihan.

q is a bronze hatchet from Morbihan.

r is the Roman *securis*. It had a single edge, or a blade and poll, as represented in the figure. When it had a blade on each side of the haft it was known as *bi-pennis*. See DOUBLE-BITTED AXE.

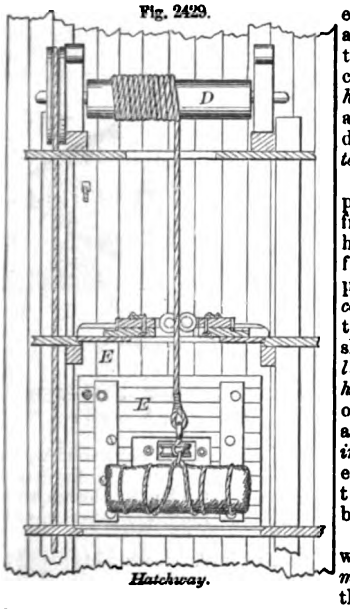
s is a shingling hatchet.

Digitized by Google

Hatch'ing. (*Engraving.*) A style of drawing or engraving in which the shading is performed by lines crossing at angles less than 90°.

Hatch'way. 1. (*Shipbuilding.*) One of the large square openings in the deck of a ship whereby freight is hoisted in or out, and access is had to the hold. The coverings are *hatches*. These are fastened down by *battens*.

Fig. 2429.



Hatchway.

There are four pieces in the frame of a hatchway. The fore-and-aft pieces are called *coamings*, and those athwart ship are *head-ledges*. The *head-ledges* rest on the beams, and the *coamings* or *carlings* extending between the beams.

The hatchways are *fore*, *main*, *after*, as the case may be, according to the size and character of the vessel.

2. An opening in the floor of a warehouse for the passage of goods. The illustration shows a part of three floors, the windlass *D* above, the hatch of the next floor closed, a floor yet lower has the hinged hatch *E* lifted and laid back against the wall.

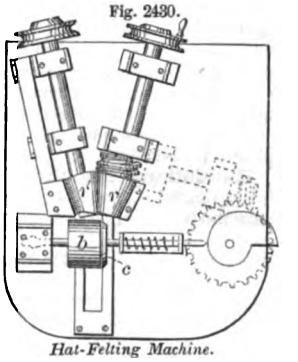
Hat-con-form'a-tor. A machine of French origin, by which the oval shape of the head is ascertained. It consists of a series of sliding arms, radially arranged in a frame, and carrying at their upper ends sharp points. When applied to the head as is a hat, the arms are thrust outward by contact with the head, and assume a position corresponding to the exact conformation thereof. While thus held an impression is taken upon a slip of paper pressed upon the points. This paper is trimmed to the form delineated by the points, and becomes a pattern by which an adjustable block is set for use in reshaping the form of a finished hat.

Hat-die. A block for holding a hat while pressing. Synonymous with HAT-MOLD (which see).

Hat-em-boss'ing. A means for beautifying the appearance of a hat, by producing a pattern upon its exterior by raising and depressing different parts of its surface. Generally done on a pattern-block upon which it is pressed. Dies are sometimes employed. A pressing tool, running in a lathe, is also used to impress a pattern.

Hat-felt'ing. A mode of forming hats by placing a disk of felting material between surfaces which by a rubbing and drawing action felt the fibers and cause the hat to gradually assume the required shape. In the example, the circular piece of felting material is placed between the disk *c* and *block b*, its outer portion being embraced between the conical rollers *r r'*. The parts being set in motion, the block is gradually slipped along its axis, causing the felt to assume the shape of the sides of the block. When the latter has been moved a distance equal to its length, the hat is formed, the remainder of it that is between the manipulators *r r'* constituting the brim.

Fig. 2430.

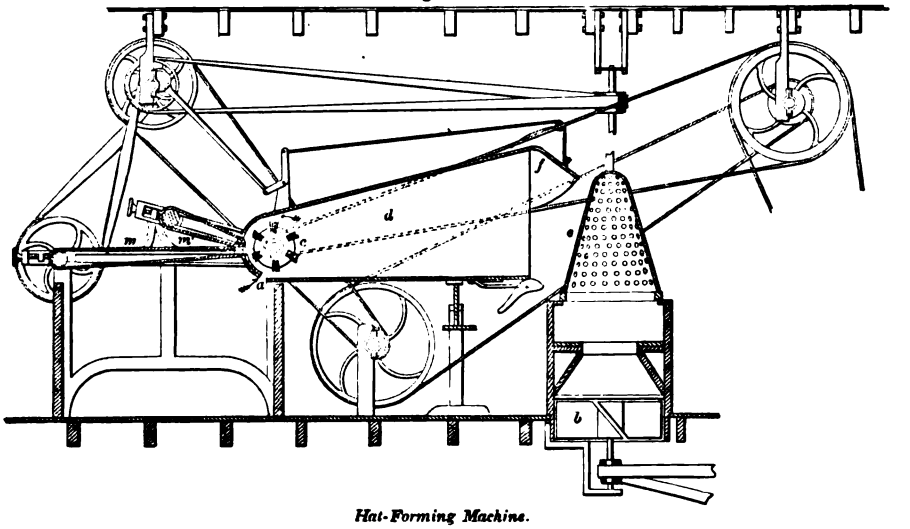


Hat-Felting Machine.

Hat-fin'ish-ing. The operations which complete a hat for market, — such as brushing to lay the nap, and ironing to smooth and impart a gloss to it; or pouncing to even the surface; or brushing to remove the dust; or dyeing and trimming.

Hat-form'ing Ma-chine'. Slivers of wool are taken from the doffer of a carding-engine and wound

Fig. 2431.



Hat-Forming Machine.

Digitized by Google

in different directions upon a cone, which revolves and traverses or vibrates to and fro, by which motions the filaments of wool are crossed at different angles, and perfect felting is accomplished.

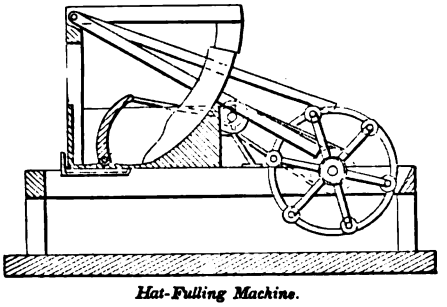
This class of machines is now superseded by that shown in Fig. 2431, which is a machine for loosening-up fiber and depositing it on a former, so as to form the hat-body. Various machines of this kind have been invented, embracing the same general principles, but differing in detail. That illustrated was patented by H. A. Wells, April 25, 1846. In this the fur, in regulated quantity, is supplied to the machine between a pair of feeding-belts *m m'*, and caught from the lips of the belts by a rotating brush or picker *c*, which separates the fibers and delivers them into the tunnel *d*, air being drawn through the aperture *a* by means of the draft caused by a fan-blower *b*, rotating with great velocity. The cloud of fur is drawn through the tunnel *d*, and deposited upon the revolving perforated cone *e*, from which the air is exhausted by the fan *b*. A vibratable deflector *f* hinged to the tunnel *d* governs the discharge of fur from the tunnel, so that an increased thickness may be given to the lower part of the hat-body.

When the charge or given quantity of fur to form a body has been deposited on the former, it is covered with a conical cloth or felt cap over which a metallic covering is placed and the whole removed from the machine, and immersed for a short time in a hot-water bath, to contract and compact the material. See also BLOWING-MACHINE, page 307.

The succeeding processes are those ordinarily employed in hat-making. See HAT; FELTING.

Hat-full'ing Ma-chine'. The function of a fulling-mill in hat-making is to thicken or consolidate the body. It commonly consists of two or more

Fig. 2432.

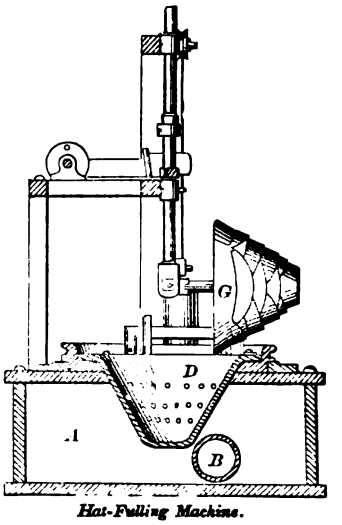


Hat-Fulling Machine.

sets of beaters or hammers, successively raised and dropped upon the mass of hats contained in the trough, where they are agitated or turned by mechanical means so as to constantly present new surfaces to the fulling-stocks. In the example the movement of the swinging side of the fulling-box causes the mass of hats to pass around regularly to insure equal action on all their parts.

In Fig. 2433 the *bat* is laid over the basin *D* and the forming-block *G* brought over it. Steam is admitted through perforations in the mold, and also in the *former*, if desired. The mold and its rim rotate continuously. The *former* has an adjustable reciprocating rotary motion, and also an up-and-down vertical one; the shingles or curved lapping surfaces serve to crowd down and aid in fulling the bat. By an automatic motion of a weight outward upon the beam-lever, a blow of gradually increasing force is given to the falling cone *G* as the work proceeds. *A* is the steam-chamber, *B* the steam-pipe.

Fig. 2433.

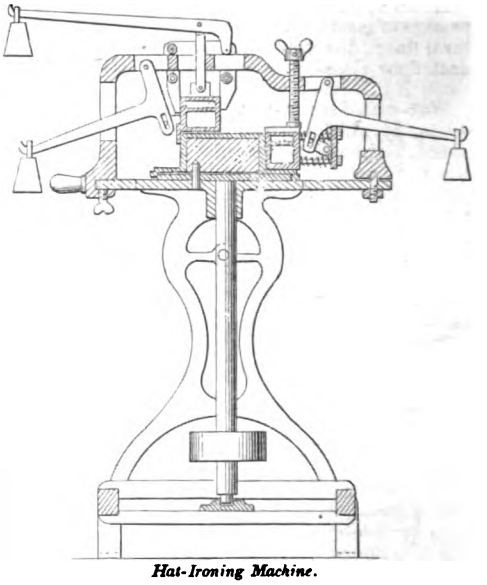


Hat-Fulling Machine.

Hat-hard'-en-ing Ma-chine'. *Hardening* or *basoning*; a preliminary felting operation which converts the fillers into a fabric dense and tenacious enough to enable it to be handled and put through the felting process. In cones from the forming-machine, it is usually done by an auxiliary cone moved over that on which the body was formed. Other bodies are steamed and rolled up in cloths (basoning-cloths). Flat bats are hardened between a table and a flat platen having short, quick reciprocating motion. See Emmon's patent, April 19, 1853.

Hat-i'ron-ing Ma-chine'. A machine for performing the ironing formerly done by hand, by

Fig. 2434.



Hat-Ironing Machine.

which the final operation of finishing a hat is accomplished.

The block supporting the body rotates at a high speed, while hollow irons, heated by interior gas-jets, steam, or hot air flowing through, or by heated slugs introduced within them, are held against the whole surface by pressure of a weight or spring. The tip-iron usually has a lip on one side, which bears over the square.

Digitized by Google

The under brim is either finished by hand or by inverting the block on the machine, so that an iron may bear upon it. In some instances the block is so supported on its spindle as to allow an iron to bear on the under brim at the same time that the crown is being treated.

In the example, the blocked hat revolves on a turn-table; the irons are pendent from an upper bridge-frame, and their pressure is regulated by levers and counterweights; the irons are heated by gas-burners.

Hat-mak'ers' Bat'ter-y. (*Hat-making.*) A large boiler with a surrounding set of benches for a number of workmen. The water has a small quantity of sulphuric acid to enable the fur to felt more readily.

At the battery the conical hat-body and the sheet of fur *napping*, each previously prepared, are united, so that the latter forms a fur covering to the former. The junction is accomplished by laying the napping

Fig. 2435.

Hat-Makers' Battery.

on the body, pressing, rubbing, and rolling with a pin. Boiling-hot water is sprinkled over them from time to time, by means of a *stopping* brush, and when a certain degree of cohesion is obtained the conical hat is ready for *shaping*.

The effect of the manipulations is to drive the butt-ends of the filaments into the interstices between the fibers of the body (see FELT), and it is persevered in no longer than is sufficient to give the nap a good hold on the body.

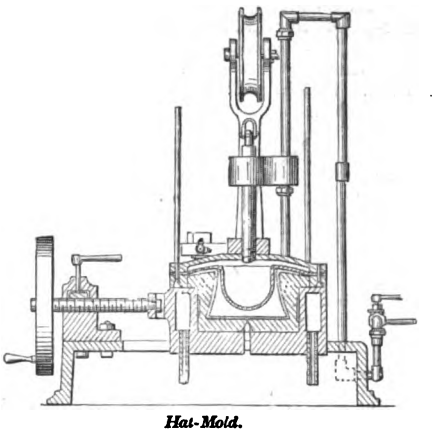
A wooden tool held in the palm of the workman's hand is the means of rubbing, and is held on by a string. It is called a *glove*.

Hat-meas'ure. A device by which the size of the oval head opening is ascertained. Usually a circular graduated ribbon, the ends of which slide in each other. See also HAT-CONFORMATOR.

Hat-mold. The die in which a hat or bonnet is formed or shaped by pressing. In the example, the *bat* to form the hat is shown as being driven into the heated mold by means of the pressure of a liquid introduced above an elastic diaphragm above the bat. See HAT-PRESSING MACHINE.

Hat-nap'ping Ma-chine'. A felted body is dipped into boiling water and its nap drawn out or carded up by a small hand-card. The process of

Fig. 2433.



Hat-Mold.

scalding in napping is described in English patent 7397 for 1837. Known also as *ruffing*.

Hat-per'fo-rat'ing Ma-chine'. A machine for cutting a multiplicity of fine holes in the hat-body to provide for ventilation.

Hat-plank'ing. A finishing felting operation. See FELTING.

The hat-body being *basoned* or *hardened* is passed through a cistern containing a heated acidulated water with dregs of beer, or other planking liquor, and between two series of pressing rollers, by which the fibers are knitted together or consolidated into felt, when they are ready for the blocking.

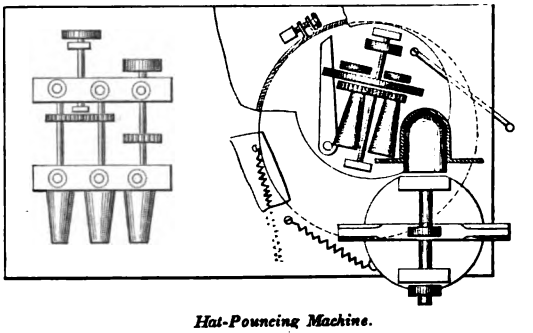
In hat-planking machines the bodies are repeatedly passed through a boiling acidulated bath and under pressure, being frequently *crozed*. See also HAT-BODY SIZING-MACHINE.

Crozing or *crosing* is refolding a hat-body so that in passing many times through a felting-machine it may present new surfaces to be acted upon.

Hat-poun'cing Ma-chine'. A machine for evening or equalizing the surface of a felted hat. It consists of a roller covered with sand or emery paper, and rapidly revolved in contact with the surface, by which the projecting fibers are ground off until the surface fibers are of equal length.

In the example, the cones are covered with sandpaper, and are mounted on shafts which have their bearings in a revolving disk in connection with a swivel plate and an adjustable revolving block on

Fig. 2437.



Hat-Pouncing Machine.

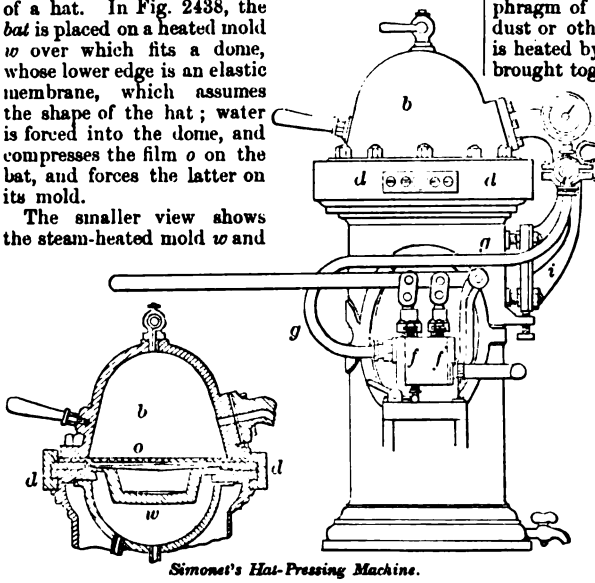
which the hats are presented to the pouncers. By the combined action of the feed and pouncing rollers

Digitized by Google

the brim is subsequently revolved automatically and operated upon by the bouncing cones.

Hat-press'ing Ma-chine'. A machine for bringing a *bat* or *cone* of hat-making material to the form of a hat. In Fig. 2438, the *bat* is placed on a heated mold *w* over which fits a dome, whose lower edge is an elastic membrane, which assumes the shape of the hat; water is forced into the dome, and compresses the film *o* on the bat, and forces the latter on its mold.

Fig. 2438.

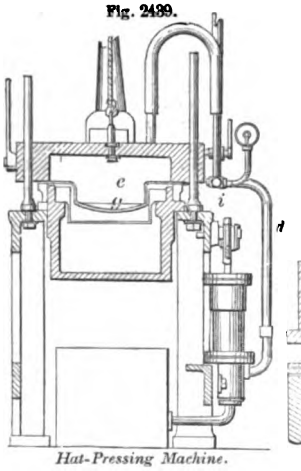


Simonet's Hat-Pressing Machine.

The smaller view shows the steam-heated mold *w* and dome *b* in section, while the larger view is a side elevation. *f f'* are the force-pumps by which water is forced into the dome *b* through the bent pipe *g* and trunnion-tube *c*, which is on an adjustable bracket *i*; the mode of connection allowing a vertical motion to the dome in closing and opening, and a horizontal motion when securing the foot of the dome in the ring *d* by means of a bayonet-joint attachment.

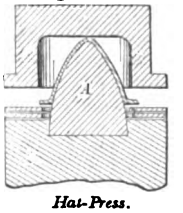
In Fig. 2439, the hat *g* is shown in process of extension downward to fill the hat-shaped mold. The pressure of water is at the first derived from a head, but as greater force is required, the cistern tap is closed and the force-pump is brought into action, injecting water through pipe *d* into the dome *e*; at *i* is a connection with a manometer which indicates the pressure.

Fig. 2439.



Hat-Pressing Machine.

Fig. 2440.



Hat-Press.

In Fig. 2440, *A* is a compressible block of rubber, which, under pressure, expands to fill the whole interior of the hollow die and press the hat-cone against the surface, while the brim is held between yielding surfaces which preserve its shape.

Fig. 2441 is a machine in which a paper, straw, or cloth hat is brought into the desired form in a hollow die, by means of a plunger formed of a diaphragm of rubber distended by packing with sawdust or otherwise. The chamber *C* behind the die is heated by steam or hot water, and the parts when brought together are secured by a bayonet-joint.

Hat-pro-tect'or. A cover approximating the shape of the hat, and applied to it to protect it in inclement weather.

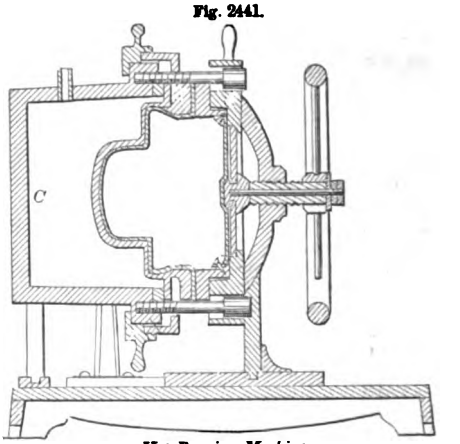
Hat-rack. A piece of hall furniture having pegs for holding hats.

Hat-shap'ing Ma-chine'. A machine for bringing the hat-body from the form of a cone to the hat shape desired. The same as HAT-PRESSING MACHINE (which see).

Hat-stiff'en-ing Ma-chine'. A machine with two compartments, one containing thin and the other thick size. Above its partition a pair of squeezing-rolls are arranged. The hats are dipped in the thin size, passed through the rolls, and then the brims (which require to be the stiffest) are dipped in the thick size, and again pressed.

Hat-stretch'ing Ma-chine'. A machine having a series of radially arranged arms, hinged to a head-block *b*, so as to be expanded. They stretch out the hat-cone, which is placed over them, and prepare it for blocking. In the example, Fig. 2442, the block is raised into contact with the stretched top of the hat, and then pushed up by means of a lever, so as to draw it up. The rubber bands fit on the body, and holds it when the stretcher-levers *B* are separated at their upper ends. The hat-cone *f* is shown as clamped to the conical system of levers by the band *T*.

Fig. 2441.

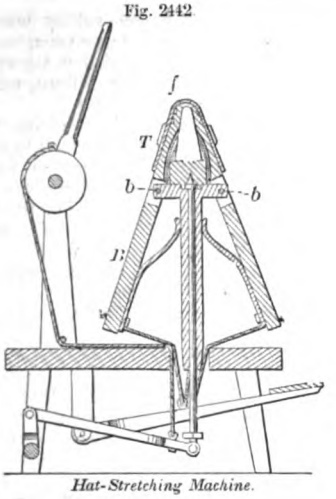


Hat-Pressing Machine.

In Fig. 2443, the pieces *b d' d'* are adapted to receive a cone supporting both the crown and brim portions; rising with the cone, they carry it against two other sets of ribs or rollers m^3 m^3 radially arranged, by which contact the body is crimped or stretched so as to have the requisite fullness to be

Digitized by Google

Fig. 2442.



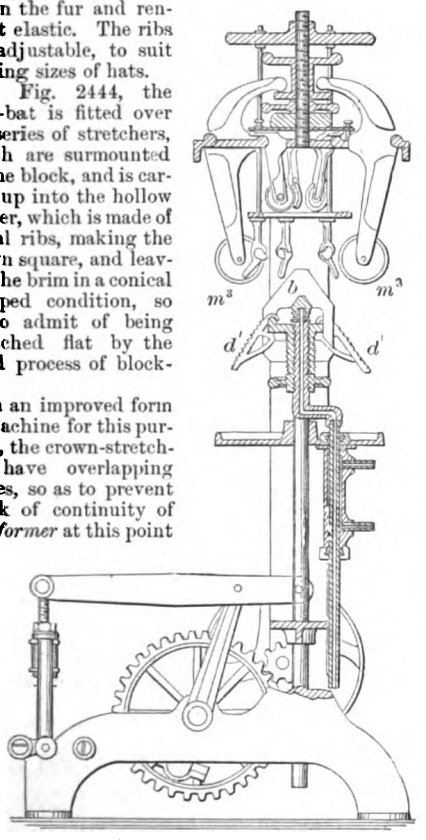
Hat-Stretching Machine.

brought into the hat form over a block. Jets of steam are introduced through the spindle to soften the fur and render it elastic. The ribs are adjustable, to suit varying sizes of hats.

In Fig. 2444, the cone-bat is fitted over the series of stretchers, which are surmounted by the block, and is carried up into the hollow former, which is made of radial ribs, making the crown square, and leaving the brim in a conical crimped condition, so as to admit of being stretched flat by the hand process of blocking.

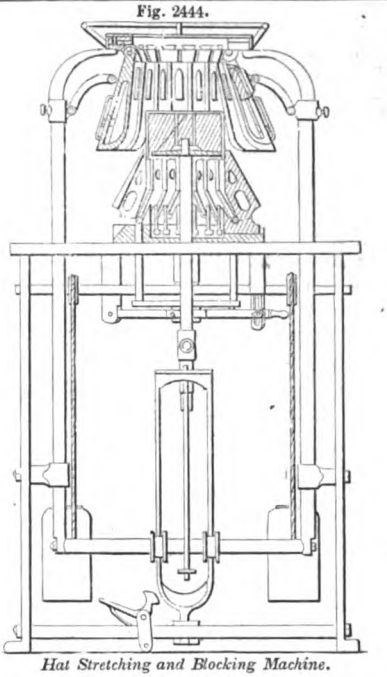
In an improved form of machine for this purpose, the crown-stretchers have overlapping plates, so as to prevent break of continuity of the *former* at this point when the parts are distended. This is also accomplished by an india-rubber cap. When the brim-stretchers clamp the brim on arriving at a horizontal plane, they expand radially, drawing the body against the banding-ring, stretching the brim circumferentially, pulling material out of the side-crown, which is thereby stretched.

Fig. 2443.



Hat-Stretching Machine.

Fig. 2444.

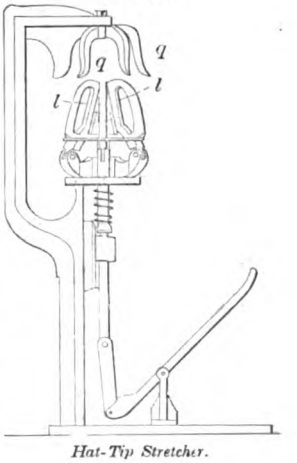


Hat Stretching and Blocking Machine.

Hat-tip Press. One in which gold printing is performed on fabric for hat-tips. The type are of brass, and kept hot. The gold-leaf is laid on the type. The leather or fabric has an adhesive material applied to it, so that the gold will remain on the impressed part and the remainder may be brushed off.

Hat-tip Stretch'er. A machine adapted for stretching the tip of the cone, so that it may be blocked flat. The top is held by the clamp, so that when the treadle is depressed and the stretchers *l* rise, they reach the hat and then expand, passing between the pendent arms *q* and crimping the tips.

Fig 2445.



Hat-Tip Stretcher.

Hat-ven'ti-la'tor. A means for promoting a circulation of air through a hat while in wear.

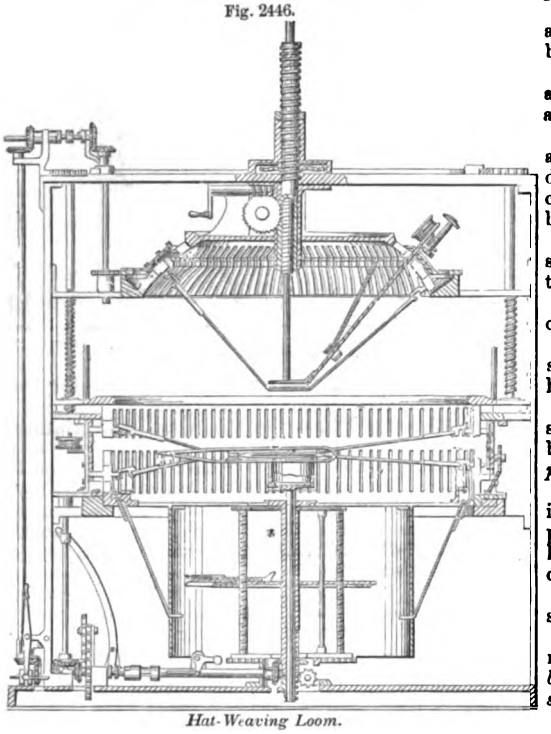
The simpler form is an aperture at the top of the crown, frequently provided with a means for closing it up. An orifice extending wholly or partially around the head opening, and formed by a perforated block interposed between the *sweat* and the *body*, acts in conjunction with the *tip* opening. The simplest and most common form is a covered crimped wire sewed between the *sweat* and *body*. The side crown is frequently filled with fine perforations, and in one

Digitized by Google

instance a stiff body pierced with large holes is covered with an open woven fabric, the pattern of which conceals the perforations.

Hat-weav'ing Loom. The warp strands for the hat are attached to carriers placed opposite each other in a circular series of partitions. The top of the crown is first woven, the warps being horizontal and moved to cross the path of the moving filling. When the top is completed the warp-carriers are removed to the upper series of partitions, and a circular or oval plate at the bottom of a follower gages the size of the crown; then, to weave the brim, the warp-carriers are removed to the lower series of

Fig. 2446.



Hat-Weaving Loom.

partitions, the crown being fitted to a hat-shaped block. During the weaving, additional warps and warp-carriers are thrown into action automatically. The edge of the brim is finished by hand, after the hat is removed from the machine.

Haul. (*Rope-making.*) A bundle of three or four hundred parallel yarns ready for tarring. Being dipped in a tar-kettle, the haul is dragged through a *grip*, *gape*, or sliding nipper which expresses superfluous tar.

Haul-up Gear. (*Saw-mill.*) A machine for dragging up logs from a fore-bay, pond, or log-yard, to be placed upon the log-carriage.

Haunch. (*Architecture.*) The shoulder of an arch between the *crown* and the *springings*. The *flank*, *haund*, or *hance*.

Haut'boy. (*Music.*) A wooden musical instrument played with a reed, and resembling a clarinet. Called also *oboe*.

Haute-pace. (Or *half-pace.*) A raised floor in a bay-window.

Hav'er-sack. 1. A strong linen bag for containing the rations of a soldier on the march or detached duty.

The haversack of the Roman soldier was an osier basket with a long neck. Sometimes, as on the Column of Trajan, a wallet carried on the spear. Its contents were salt meat, cheese, onions, and olives, and it held sufficient for three days.

2. A gunner's case for carrying a charge from the chest to the gun. See GUNNER'S HAVERSACK.

Hawk. (*Plastering.*) A piece of board ten inches square, and held by a handle at the bottom; it is used to hold a small quantity of plaster, and is grasped by the plasterer's left hand, while his right wields the trowel.

Hawk-bill. A pliers with curved nose, to hold pieces in blow-pipe soldering.

Hawk-bill-tooth Saw. A saw having a curving, hooked saw-tooth, somewhat resembling the upper mandible of the hawk.

Hawk'er. (*Nautical.*) A vessel built like a *pink*, but rigged like a *hoy*; that is, having a narrow stern and *sloop-rigged*.

Hawks-bill. (*Horology.*) A catch-piece attached to a vibrating arm, which acts as a detent in the rack of the striking part of a clock, and assists in effecting the proper number of strokes.

Hawse. (*Nautical.*) *a.* That part of a ship's bow in which are the *hawse-holes* for the cable.

b. The situation of a ship moored with anchors from each of the bows.

Hawse-bag. (*Nautical.*) A canvas bag stuffed with oakum, to stop a hawse-hole in heavy seas.

Hawse-block. (*Nautical.*) A block for stopping the *hawse-hole* when the cable is unbent and the ship at sea. Also called *hawse-plug*, *buckler*, etc.

Hawse-hole. (*Shipbuilding.*) A hole in the bow through which a cable or hawser passes. In iron ships it is a cast-iron tube having rounded projecting lips, inside and outside.

When the cable is unbent, the hole is stopped by a *hawse-block*, or *hawse-plug*.

The *hawse-holes* in large ships are four in number, the foremost pair being for the *bower-cables*, and the aftermost pair for the *sheet-cables*.

Hawse-piece. (*Shipbuilding.*) *a.* One of the cant-frames standing next to the knight-heads, and fitting close together, so as to form a solid mass of timber for the passage of the hawse-holes.

b. A wale on a ship's bow, which is pierced by the hawse-hole.

Hawse-pipe. (*Nautical.*) The tube lining a hawse-hole in a ship's bow.

Hawse-plug. (*Nautical.*) A HAWSE-BLOCK (which see).

Haw'ser. (*Nautical.*) A small cable, used in warping and mooring.

A *clear* hawse is when two cables are down and diverge from each other.

A *foul* hawse is when they are twisted by the swinging of the ship at her moorings.

When simply crossed, it is called *cross*-hawse; another cross makes an *elbow*; another makes a *round-turn*.

Disengaging it is called *clearing hawse*. Slackening it is called *freshening hawse*.

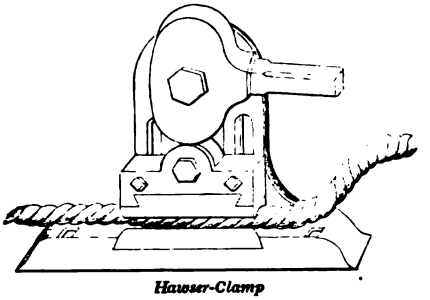
Speaking generally, a hawser is not over ten inches in circumference. Above this it is a cable. The *laying*, however, is not to be disregarded.

Haw'ser-clamp. (*Nautical.*) A gripper for a

Digitized by Google

hawser, to keep it from veering out. In the example, the lever is recessed so as to form a flange which acts as a cam upon a pin for the purpose of raising the guide with the movable jaw. The guide has a

Fig. 2447.



Hawser-Clamp

rib running in a slot in the upright bracket to which it is bolted. See CABLE-STOPPER.

Haw'ser-laid. (*Rope.*) Rope made of three strands, of three yarns each, *laid up* into a rope. The twist of the strands is the reverse of the individual yarns.

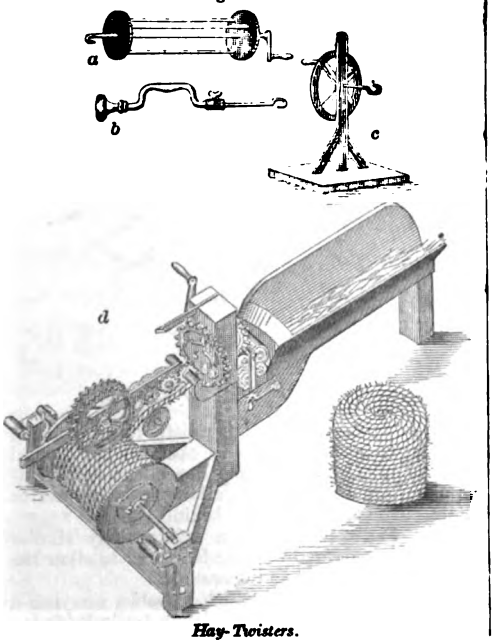
Shroud hawser-laid has four strands.

Three *hawser-laid* ropes are laid up into a *cable*, the twist being again reversed.

Hay-band Ma-chine'. (*Husbandry.*) Hay or straw bands are useful in binding an occasional bunch or sheaf of straw or hay, or for throwing over a new stack to hold the cap on until it has time to settle. They are made by drawing and twisting, as in the more elegant and precise operations of spinning cotton and wool.

A common device for this purpose is a reel or lantern cylinder *a* held under the left arm, while the right hand turns the crank and the axis, on whose end is a hook to which a wisp of hay is attached.

Fig. 2448.



Hay-Twisters.

The operator walks away from the bunch of hay, or an assistant pays out the hay in the quantity required.

A brace and hook *b* answer the same purpose.

Instead of the brace and hook, another device *c* may be used, in which the axis of the twister is mounted in a stand. One person turns the wheel and another catches a wisp into the hook and then backs out, like a rope-maker.

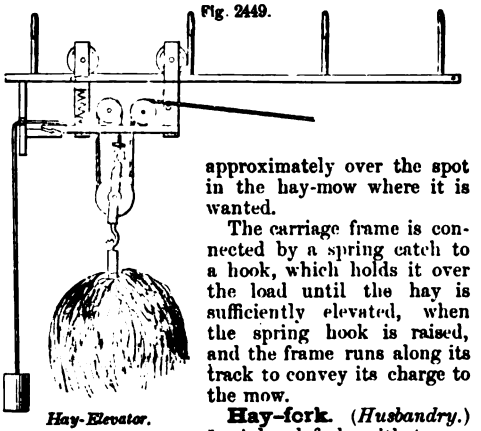
d is a machine which makes hay rope and winds it up into a coil for transportation. Rollers draw the hay from the trough, and the twisting is effected by a planetary action of the rollers longitudinally. It is then coiled on the reel.

Hay-cap. (*Husbandry.*) A piece of canvas to lay on the top of a haycock to shed rain.

Hay-cut'ter. (*Husbandry.*) A box in which hay is cut into chaff. There are many forms: wheels with radial knives, which cut into each other's intervals, or against a cylinder of rawhide; guillotine knives with a shear cut; rotary shearing knives, which glance athwart the throat at which the compacted mass of hay emerges, and so on. See STRAW-CUTTER.

Hay-el'e-va'tor. (*Husbandry.*) A means for lifting a forkful of hay, and conveying it to a place

Fig. 2449.



Hay-Elevator.

approximately over the spot in the hay-mow where it is wanted.

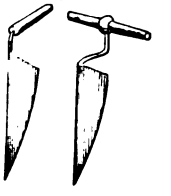
The carriage frame is connected by a spring catch to a hook, which holds it over the load until the hay is sufficiently elevated, when the spring hook is raised, and the frame runs along its track to convey its charge to the mow.

Hay-fork. (*Husbandry.*) 1. A hand fork, with two or three tines, for stirring or pitching hay.

2. A fork elevated by a rope and horse, in unloading hay from a wagon to a mow, or *vice versa*. See FORK.

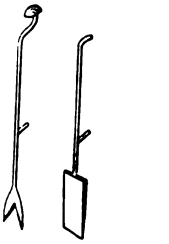
Hay-hook. (*Husbandry.*) An implement for pulling hay out of a mow or stack, instead of throwing it off the top, or cutting it off with a hay-knife. Such hooks are common in the Eastern States, but not in the West. Such a hook is described and pictured, page 893, Tome 5, "Encyclopédie de l'Agriculteur," Paris, 1861.

Fig. 2450.



Hay-knife. (*Husbandry.*) The *hay-knife* has a straight blade, one edge, and a bent shank, so that the hand does not come in contact with the upright face of the stack. The same effect is obtained by placing the handle at right angles to the plane of the blade.

The hay-spade has a sharp blade, a handle, and a tread. One form has a re-entering angle with sharpened edges. It is said to be peculiarly efficient.



Hay Knives.

Digitized by Google

Hay-load'er. (*Husbandry.*) A device attached to a wagon to collect or raise the hay from the swath, windrow, or cock, and deposit it on the wagon.

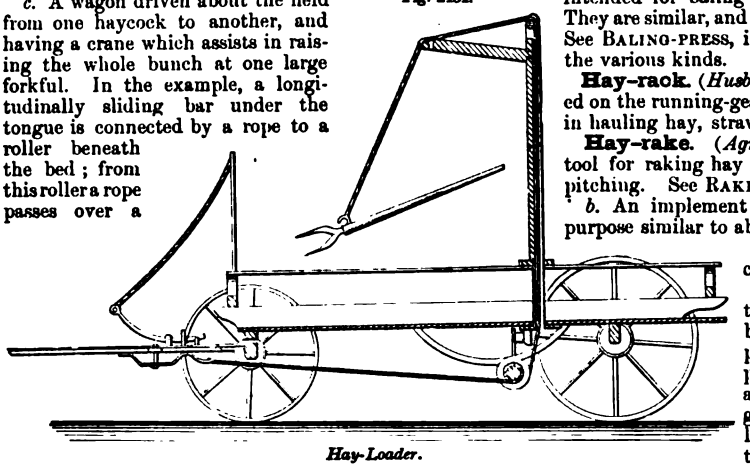
There are several forms: —

a. A rake trailing behind the wagon or alongside of it, and a traveling band with teeth carrying up the hay and dropping it into the wagon rack or bed. (See Fig. 2458.)

b. A drag-rake gathering the hay, and a crane on the wagon lifting it therefrom.

c. A wagon driven about the field from one haycock to another, and having a crane which assists in raising the whole bunch at one large forkful. In the example, a longitudinally sliding bar under the tongue is connected by a rope to a roller beneath the bed; from this roller a rope passes over a crane to the loading-fork. The draft on the rope applies the rubbers to the wheels.

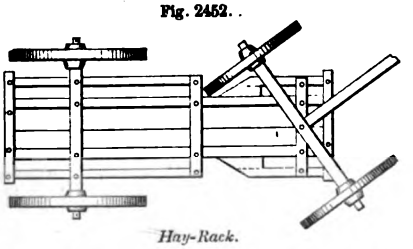
Fig. 2451.



Hay-Loader.

d. A crane on wheels or a sled. A mast or tripod on a sled.

Fig. 2452.



Hay-Rack.

Hay-mak'ing Fur'nace. Mr. Mechi writes to the "London Times" that he shall hereafter arrange to make his hay by furnace-heat. The apparatus consists of a coke-furnace, and a fan by which the heat is driven through a small chamber filled with grass. In fifteen minutes the grass is converted into hay, sweeter and greener than can be made by sun-drying. The apparatus works in all weathers, and dries grain, corn, and roots as well.

Hay-press. (*Husbandry.*) A press for baling loose hay for greater compactness in storage and transportation. The old form is the lever or screw; latterly much ingenuity has been exercised in this direction, some machines being especially intended for baling hay, others for cotton. They are similar, and are considered together. See BALING-PRESS, in which place are cited the various kinds.

Hay-rack. (*Husbandry.*) A frame mounted on the running-gears of a wagon, and used in hauling hay, straw, sheaves, etc.

Hay-rake. (*Agriculture.*) *a.* A hand-tool for raking hay into windrow ready for pitching. See RAKE.

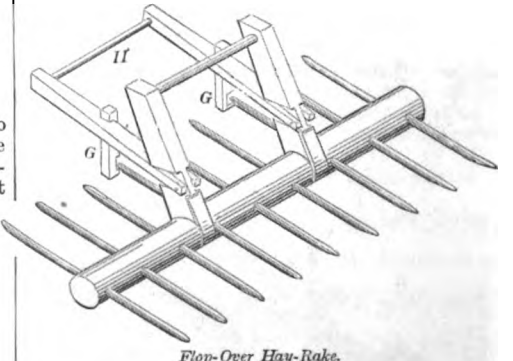
b. An implement drawn by a horse for purpose similar to above.

There are several typical forms: —

1. A series of curved teeth depending from a bar behind an axle supported on wheels. The points of the teeth trail along the ground and gather the hay, which collects in the bend of the teeth. To discharge the collected load, the teeth-bar is rotated on its axis, lifting the points of the teeth, while the clearer bars protruding behind the axle sweep the hay from the teeth. This motion of the teeth is by means of a lever which is conveniently placed for the driver.

2. Another type is that shown in Fig. 2454, in which the rake-head rests on the ground, the front ends being tipped down sufficiently to catch the hay as it lies in the swath. When a load has collected

Fig. 2454.



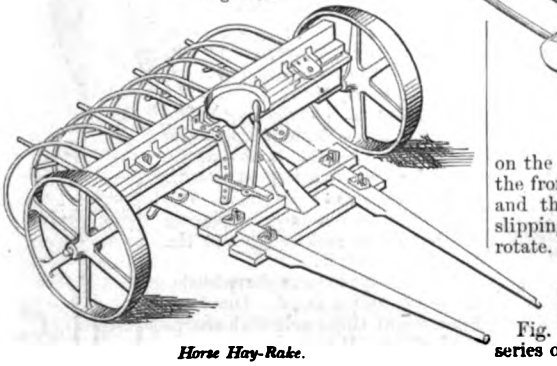
Flop-Over Hay-Rake.

on the rake, the handle *H* is a little raised, causing the front ends of the teeth to catch in the ground and the rake to upset, the dependent catcher *G* slipping from the teeth, to allow the rake-head to rotate. The operator walks behind.

Fig. 2455 shows a substantially similar rake mounted on wheels, so as to allow the person to ride and operate it.

Fig. 2456 is a form in which a frame, carrying a series of rakes on an endless band, trails behind a

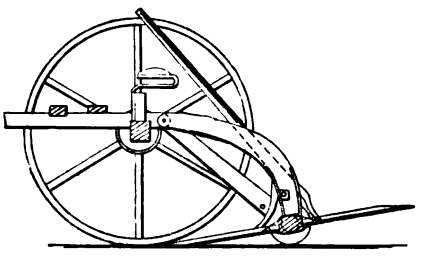
Fig. 2453.



Horse Hay-Rake.

Digitized by Google

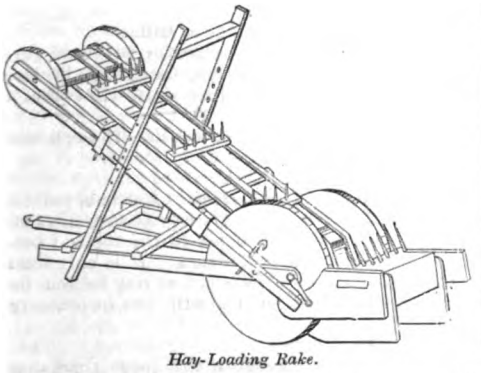
Fig. 2455



Horse Hay-Rake.

wagon so as to rake up from the swath and discharge it on to the vehicle. After the wagon is loaded the raking-frame is detached and left in the field, or attached to another wagon. See also RAKE.

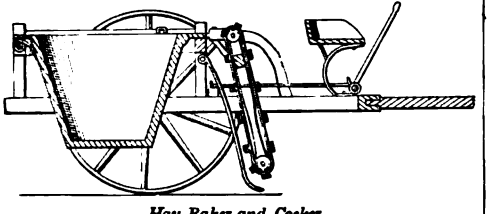
Fig. 2456.



Hay-Loading Rake.

Hay Rak'er and Cock'er. (*Husbandry.*) An implement for raking hay in the swath and cocking it. In the example, the hay is gathered by a rake, carried up by an endless elevator, and received in a

Fig. 2457.



Hay Raker and Cocker.

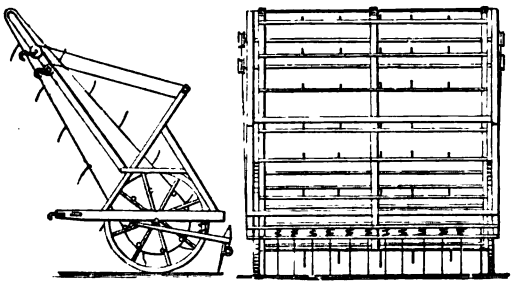
conical receiver which is inverted when filled, leaving the haycock upon the ground.

Hay-rak'er and Load'er. (*Husbandry.*) An implement for raking hay in the swath and delivering it on to a wagon. It is usually attached to the hind axle of the wagon, and is dragged in the rear, a rake gathering up the hay in the swath as the wagon goes over the ground; a traveling apron with teeth lifts the gathered hay, carries it up, and discharges it on to the wagon. When the wagon is loaded the implement is detached.

Hay-spread'er. (*Husbandry.*) A machine for scattering cut hay to expose it to sun and air. A *tedder.* (See Fig. 2460.)

Hay'stack-boil'er. (*Steam.*) A tall form of steam-boiler introduced by Smeaton, and shaped like a kettle or a haystack, with flaring sides and rounded top.

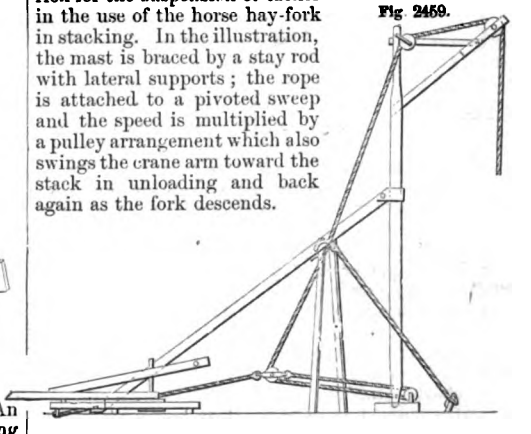
Fig. 2458.



Hay Raker and Loader.

Hay-stack'er. (*Husbandry.*) A portable derrick for the suspension of tackle in the use of the horse hay-fork in stacking. In the illustration, the mast is braced by a stay rod with lateral supports; the rope is attached to a pivoted sweep and the speed is multiplied by a pulley arrangement which also swings the crane arm toward the stack in unloading and back again as the fork descends.

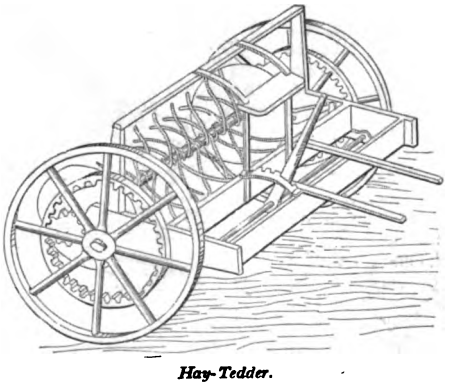
Fig. 2459.



Hay-Stacker.

Hay-ted'der. (*Husbandry.*) A machine to scatter hay to the sun and air. The hay-tedder was invented about 1800 by Salmon of Woburn, England, and is more useful in the humid climate of that country than in the United States. It consists of a pair of wheels supporting a reel consisting

Fig. 2460.



Hay-Tedder.

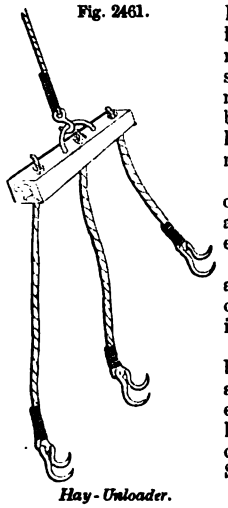
of an open cylindrical frame, formed by arms proceeding from it, and carrying bars set with curved tines, pointing outward. This reel may be lifted

Digitized by Google

out of operative position when going to and from work in the field, and when at work is rotated by pinion connection to a spur-wheel in the hub of one wheel.

Hay-un-load'er. (*Husbandry.*) A device for bringing the power of a horse to bear in unloading a load of hay in stacking or mowing. The example shows a triple claw which may be made to grasp a bunch of hay, but the horse hay-fork is the usual implement. See FORK.

Fig. 2461.



Hay-Unloader.

Head. The upper end or portion of an object or of a mast, sail, page, column, etc. The other end is the *foot*.

The larger end of a thing, as of a nail, bolt, screw, cane, etc. The other end is the *point* or *tip*.

The effective portion or blade of a tool or weapon, as of a spear, axe, hammer, etc. The other end is the helve, stock, handle, according to circumstances. See HANDLE.

1. (*Machinery, Forging,* etc.) *a.* The striking portion of a hammer, as distinguished from the helve.

b. The *poll* of a hammer, as distinguished from the *claw* or the *peen*, as the case may be.

c. The upper or steel portion of an anvil. The surface is the *face*.

d. That stock of a lathe containing the *live-spindle*. A *poppet*. The other stock is the *tail-stock*, and contains the *dead-spindle*, — as it does not rotate. See LATHE.

2. (*Books*, etc.) *a.* The top of a standing book; sometimes gilded to allow the dust to be blown off. The lower end is the *foot*.

b. The upper end of a page or column.

c. A *sunk-head* is a blank portion at the beginning of a book or chapter.

d. The cross-beam of a printing-press.

3. (*Shipwrighting* and *Nautical.*) *a.* The fore-part, *beak*, or *stem* end of a vessel, the after end being the *stern*.

b. A figure-head, or ornamental device on the prow. According to its character, it is known as a *billet-head*, *bust-head*, *family-head*, *fiddle-head*, *scroll-head*, etc.

c. The upper part of a timber in a frame. The other end is the *heel*.

d. The part of a mast between the *hounds* and the *top*.

e. The forward end of a bowsprit.

f. The top or *drum* of a capstan.

g. The flattish part of a *dead-eye* at the side of the channel or groove.

h. The upper edge of a sail. The lower end is the *foot*.

i. The fore-foot of the keel.

4. (*Carpentry.*) *a.* The top of a *door*, *window*, or *bay*; as a *circular* head.

b. The top-beam or ridge-beam of a bridge or trestle.

c. The square block which slips on the stem of a gage, and carries the scribe.

5. (*Founding.*) The *sprue*, *sullage-piece*, or *riser* on a casting, which is knocked off.

6. (*Mining.*) *a.* The end of *gallery* or *drift*. The *heading* is a passage excavated in the line of an intended tunnel.

b. The top part of a fuse, containing the priming.

7. (*Spinning.*) The system of rollers in a DRAWING-FRAME (which see).

8. (*Hydraulics.*) *a.* The vertical hight or available fall of water from a dam, race, reservoir, standpipe, or forebay; or the difference between the hights of water inside and outside a dock-gate or lock-gate. The vertical pressure usually expressed in pounds.

b. The up-stream end of a canal-lock.

9. (*Architecture.*) The capital (*caput*, head) of a column.

10. The cover of an alembic or still.

11. (*Fortification.*) The salient or advanced portion of a work. A work covering the end of a bridge.

12. (*Coopering.*) That which closes the end of a cask.

13. The *obverse* of a coin or medal. The opposite side is the *reverse*, or *tail*.

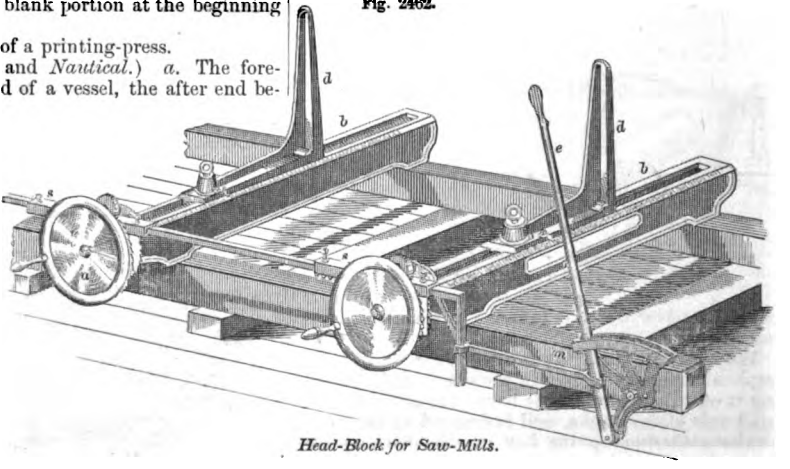
14. The *cap* of a windmill.

Head-band. (*Bookbinding.*) A strip of plaited silk over a mill-board core, or a projecting fillet of fabric which serves as a finish to the top and bottom of the sheets inside the back. It is only used in binding of superior character, as may be seen by comparing a fine calf binding with one in ordinary cloth.

Head-bay. (*Hydraulic Engineering.*) That part of a canal-lock between the upper pond and the head-gates of the lock. See CANAL-LOCK.

Head-block. 1. (*Saw-mill.*) *a.* The block on which the head — or forward end — of a log rests in the ordinary saw-mill; the other end is the tail-block, and they are parts of the carriage on which the log is moved to the saw and gigged back.

Fig. 2462.



Head-Block for Saw-Mills.

b. One of the pieces forming the log-bed in a circular or veneer saw mill. (See CIRCULAR SAW.) In the example the sliding knees *d* form abutments for the log which rests on the head-blocks *b*, and are

Digitized by Google

moved by screws in the head-blocks. On the ends of the screws are the wheels *a*, which are moved simultaneously by the lever *e*, rod *m*, and racks *s s*.

2. (*Vehicles.*) A piece of wood attached below to the upper ring of the fifth wheel and above to the front spring, also having the front end of the perch mortised through its middle.

Head'er. 1. (*Bricklaying.*) A brick laid with its end or *head* in the face of the wall. It acts as a bond. Bricks laid lengthwise are *stretchers*. See BOND.

2. (*Husbandry.*) A form of reaper. See HEADING-MACHINE.

Head-fast. (*Nautical.*) A rope by which the *head* of a vessel is made fast to a quay or vessel alongside.

Head-gate. (*Hydraulic Engineering.*) *a.* One of the upper pair of gates of a canal-lock. See CANAL-LOCK.

b. A *crown*-gate, *flood*-gate, *water*-gate, by which water is admitted to a race, run, sluice, etc.

Head-gear. (*Harness.*) The bridle of a horse. The head-stall and bit.

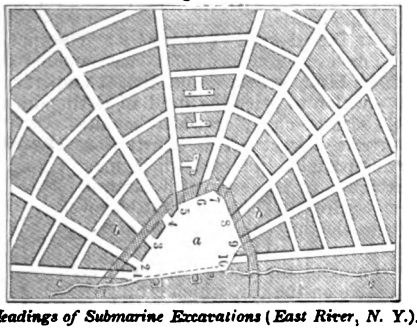
Head'ing. 1. (*Mining.*) *a.* The end of a drift or gallery, as "the *heading* is in solid rock and is *driven* by blasting and quarrying."

b. A *gallery*, *drift*, or *adit* in a mine; or in the line of an intended tunnel, especially one of relatively small size, which forms a *gullet* in which the workmen labor, and which is afterwards enlarged by extension sideways and downward to constitute a tunnel.

c. A horizontal passage between the shifts or turns of the working parties.

The illustration shows the headings driven into one of the submarine rocks which render the navi-

Fig. 2463.



Headings of Submarine Excavations (East River, N. Y.).

gation of the East River, N. Y., so dangerous. *a* is the shaft; *b*, coffer-dam; *c*, shore line. The headings are all tunnels, and it is the intention to blow up the roof, all the rock to fall back into the cavity.

2. (*Coopering.*) The pieces which compose a cask-head. The central piece is called the *middle*, and the side pieces the *cants*.

3. (*Sewing.*) The extension of a line of ruffling above the line of stitch.

4. (*Fireworks.*) The device of a signal-rocket; such as a *star-heading*, a *bounce-heading*.

5. (*Masonry.*) A course of *headers*; the ends of the stones presented outward.

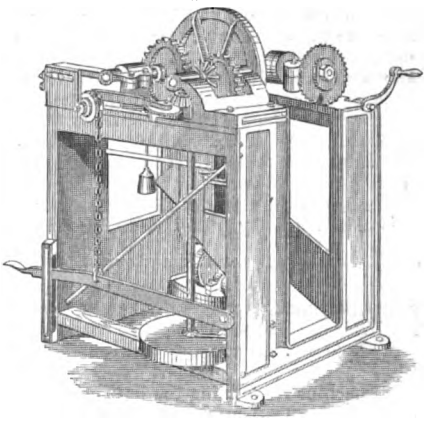
6. (*Books.*) *a.* An inscription at the head of an article, written or printed.

b. A running-title at the top of a page.

Head'ing-chis'el. A chisel for cutting down the head of a mortise. A mortise-chisel.

Head'ing-cir'cler. (*Coopering.*) A machine for cutting down and dressing the pieces to form the head of a cask. The heading stuff is clamped between two disks, trimmed circular by a saw, and dressed by revolving cutters.

Fig. 2464.



Heading-Circler.

Head'ing-course. (*Bricklaying.*) A horizontal course of bricks or masonry in which the pieces are laid with their heads in front; that is, across the thickness of the wall.

Head'ing-joint. 1. (*Joinery.*) A square or butting joint of two pieces, as of sections of hand-railing, floor boards, etc. The junction is secured by dowel, tongue, and groove, or otherwise.

2. (*Masonry.*) The joint between two voussoirs in the same course.

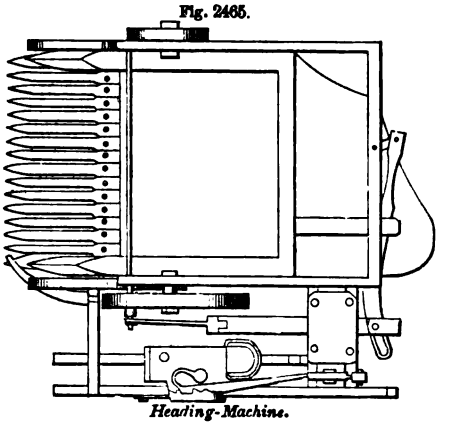
Head'ing-knife. 1. (*Saddlery.*) A round-headed knife used to cut out holes in leather, too large for the application of punches, and smaller than are conveniently made by the *round-knife*, which is the ordinary cutting-tool of the saddler.

2. The currier's knife with one straight and one cross handle, and a turned-over edge. It is used in scraping hides and reducing them to an even thickness. (Fr. *couteau à revers.*)

3. (*Coopering.*) A knife for cutting the chamfer of the head of a cask.

Head'ing-ma-chine'. 1. (*Agriculture.*) A machine for cutting off the heads of grain in the field, instead of harvesting the whole straw. The machine was tried awhile in Illinois, but its use is believed to have been abandoned except in California. The machine is now always associated with a traveling thrasher, the ripe heads of grain being cut

Fig. 2465.



Heading-Machine.

off, thrashed, and bagged. These machines vary in their cutting apparatus; some have the reciprocat-

Digitized by Google

ing knife usual with reapers, a reel sweeping the heads into a well, from which they are raised by a conveyor to the thrashing-cylinder, and thence pass to the sieves and fan.

Another favorite form is a comb with long teeth of a lance shape; the comb presents its teeth towards the grain, the stalks pass between the teeth, and, reaching the narrow portion, the head is detained and torn off, or is cut off by a revolving brush, a rotating reel, or a traveling belt with scrapers.

The *header* is the oldest form of reaping-machine, and is mentioned by Pliny and Palladius. See REAPER.

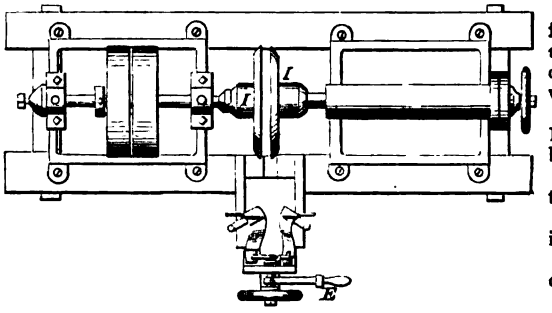
Clover-seed is also harvested in this way, the machine simply tearing off or cutting off the heads. See CLOVER-HEADER.

2. (*Metal-working.*) A machine in which bolt blanks are headed by swaging between dies, or upsetting.

3. A machine for forming the heads of pins.

4. (*Coopering.*) A machine for making heads of casks. The *middle piece* and *cants* are jointed and

Fig. 2466.



Heading-Machine.

doweled together and placed between two circular disks *I I*, so arranged upon lathe mandrels that the stock from which the head is to be cut is placed between the heads and clamped by screwing up the loose mandrel; when the heads are revolved, the heading passes between two adjustable arms, having the tools that cut the head to the desired diameter, and bevel the edge at the same time. These arms can be changed to cut heads of greater or less diameter by turning a graduating screw, or they can be expanded to work thicker stuff by oscillating a lever *E* that works a shaft, to which, on the opposite sides, are short levers pivoted to the arms.

Fig. 2467.

Heading-Tools.

Head'ing-tool. (*Forging.*) A tool used in swaging heads on stems of bolts. The rod is run through the hole of the required form and size, and the projecting portion is *upset* or hammered down, forming a knob. This is brought to shape by a swage. A swage with an angle of 60° is used for making hexagonal bolt-heads. (See Fig. 2467.)

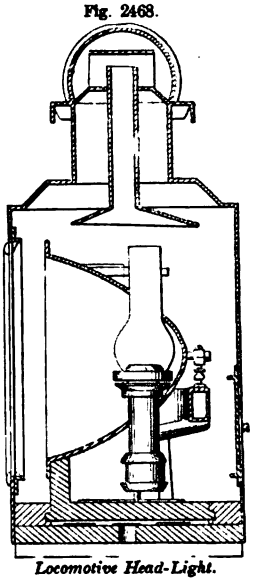
Heading-tools for nail, rivet, and brad forgers are made like nippers to open and release the nail, etc., after the head is swaged down.

Head-knee. (*Shipbuilding.*) A piece of compass-timber fayed edgeways to the stem and cutwater. A *cheek-knee.*

Head-ledge. (*Shipbuilding.*) One of those portions of the raised rim around the edge of a hatchway which run athwart ship. The parts running fore and aft are *coamings.*

Head-light. (*Railway.*) The light carried at the front end of a locomotive, to illuminate the way and act as a signal. It has usually an oil-lamp, whose flame is in the focus of a parabolic reflector. In the example, the lamp is of the Argand variety, air being admitted to the center and around the tubular wick, while the heated air is received from the chimney by a flue above.

Fig. 2468.



Locomotive Head-Light.

Head-line. 1. (*Printing.*) The top line of a page in which the running-title and folio are given.

2. (*Nautical.*) The rope at the head of a sail.

Head-mold'ing. (*Architecture.*) A molding over a door or window.

Head-plate. 1. (*Artillery.*) The plate which covers the breast of the cheeks of a gun-carriage.

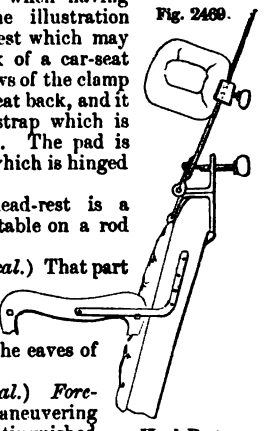
2. (*Saddlery.*) The plate strengthening the point or *cantle* of a saddle-tree.

Head-post. A stanchion by the manger, in a stable.

Head-rail. (*Carpentry.*) The upper rail, or horizontal piece of a door-frame.

Head-rest. A cushion or support against which to place the head in sitting in a car-seat or chair, or when having a portrait taken. The illustration shows a portable head-rest which may be attached to the back of a car-seat when required. The jaws of the clamp embrace the top of the seat back, and it is held in place by a strap which is passed around the back. The pad is adjustable on the bar, which is hinged to the clamp.

Fig. 2469.



Head-Rest.

The photographic head-rest is a cushion vertically adjustable on a rod supported by a tripod.

Head-rope. (*Nautical.*) That part of a bolt-rope sewed to the head of a sail.

Heads. (*Roofing.*) Tiles which are laid at the eaves of a house.

Head-sail. (*Nautical.*) *Foresail.* For purposes of maneuvering ships, the sails are distinguished into *head* and *after* sails; *head-sails* comprehending all sails whose centers lie before the general center of effort of all the sails, and *after*-sails, all whose centers lie abaft that point.

Head-stall. (*Menage.*) *a.* The bridle minus the bit and rein.

b. The halter minus the hitching-strap.

Head-stick. 1. (*Printing.*) A piece of furniture forming the margin at the heads of pages.

2. (*Nautical.*) A short, round stick, with a hole at each end, through which the head-rope of some sails is thrust.

Digitized by Google

Head-stock. 1. (*Lathe.*) That portion of a lathe which contains the mandrel or *live* spindle on which the work is chucked or to which it is dogged, in contradistinction to the *tail*-stock which contains the *dead* spindle. The *live*-head as distinguished from the *dead*-head.

2. The head which supports the cutters in a planing-machine.

Head-tim'ber. (*Shipwrighting.*) A crooked timber in the frame of a ship's head, to support the gratings. A *bracket.*

Head-valve. (*Steam-engine.*) The delivering valve. The upper air-pump valve.

Head'way. 1. The clear hight of a passage-way, tunnel, gallery, doorway, arch, etc.

2. A gallery at right angles to the main passage-way to the shaft of a coal-mine. A *heading.*

Healds. (*Loom.*) The harness for *shedding* the warp-threads in a loom. The *heddle.* The threads are doubled in pairs, and arranged in sets so as to shift the warp-threads as may be required for plain, twill, or figured weaving.

Heal'ing. (*Roofing.*) The covering a roof with lead, tin, slates, etc.

Heap. 1. (*Printing.*) The pile of wet paper to be fed to, or of printed paper delivered from, a press.

2. (*Mining.*) The refuse or sterile gangue thrown into a pile.

3. The pile of wood stacked for burning into charcoal.

Hear'ing-trum'pet. An acoustic instrument to collect a larger volume of sound and conduct it to the ear. See EAR-TRUMPET.

Hearse. A carriage for the conveyance of dead bodies. In the hearses of the ancient Egyptians we may see traces of the fabled "passage across the lake" which separated the land of life from the land of death, and from which the Greeks derived their Styx and Charon. The legendary custom was to hold an assize at the point where the corpse was embarked, to determine whether the deceased had by

Fig. 2470.

Egyptian Hearse.

his virtues or atonement merited the land of rest. When the determination was favorable, the bier was placed on the boat, which bore his remains to the city of silence. In after times, — as it would seem, — when no lake intervened, the bier or body of the hearse was made to represent a miniature boat, with lilliputian rowers, and was mounted on four wheels, or on runners. Instances of both occur in the sepulchral paintings, and the car is shown drawn by oxen or men, and sometimes by both. The Greeks preserved a portion of the legend, turned the practical into the mystical, as usual, in time forgot all about the moral, and degraded the grand assize into a morose old waterman, a great stickler for pennies, and not afraid of ghosts.

Hearses in England are not noticed till the time of James II. Previous to this time, bodies were carried on men's shoulders, on biers, or on horse-litters.

Heart. 1. The interior, as of wood. The solid portion divested of sap-wood or alburnum.

2. The central solid portion or core of a twisted column.

3. (*Nautical.*) *a.* A dead-eye of triangular shape, having but one eye, whose lower edge has *scores* for the lanyard which hauls taut the backstay occupying the outside *groove.*

Fig. 2471.

Hearts.

Collar-hearts are open at the lower ends; a double score is cut round the outside, and two grooves on each side for the seizing, which keeps the collar in the scores of the heart.

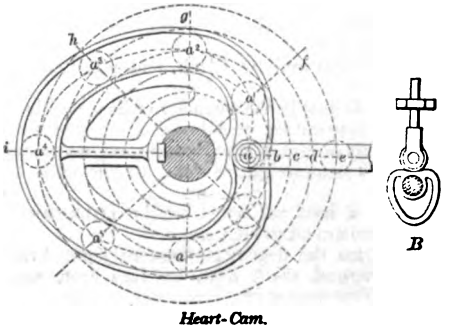
b. The inner part of a shroud-laid rope.

4. A heart-shaped wheel or cam used for converting a rotary into a reciprocating motion. See HEART-CAM.

Heart-bond. (*Masonry.*) A bond in which no header-stone stretches across the wall, but two headers meet in the middle, and their joint is covered by another stone laid *header* fashion.

Heart-cam. A form of cam which serves for the conversion of uniform rotary motion into uniform rectilinear reciprocating motion. The principle of its construction is, that for each successive equal part of one half revolution of the cam, the rod must have been moved by its periphery through a corresponding equal part of the entire stroke. If *a e* represent the stroke required, then divide the same into any number of equal parts, *a* – *b*, *c* – *d*, *d* – *e*, and describe from the center of rotation circles passing

Fig. 2472



Heart-Cam.

through these points of division; divide half the circumference of these into as many corresponding equal parts, and draw radial lines through the points of division *e f g h i*, then a^1 a^2 a^3 a^4 will represent the successive positions of the point of the rod as the cam revolves, and of course for the return stroke these divisions will recur in the reverse order. To lessen the friction, the rod is provided with a roller, to suit which two equidistant curves are made, forming a groove in which the roller runs.

Hearth. 1. (*Metallurgy.*) The floor in a reverberatory furnace on which ore, metal, etc., is exposed to the action of the flame from the furnace. The hearth has a domed ceiling, and is divided from the furnace by a *bridge*, over which the flame passes. See REVERBERATORY-FURNACE.

2. The floor of a fireplace.

Hearth-brush. (*Domestic.*) A small hair broom for brushing up ashes and tidying around the hearth of an open grate.

Hearth-ends. (*Metallurgy.*) Particles of unreduced lead ore, expelled by decrepitation and the blast from the lead-smelting furnace. This becomes

Digitized by Google

mixed with lime and fuel used in smelting, and is collected from time to time, is washed to remove earthy particles, and then smelted.

Hearth-plate. (*Metallurgy.*) A cast-iron plate forming the sole of the hearth of a forge or refinery furnace.

Heart-wheel. This is one form of cam-wheel, which acts by a regular impulse and recession to reciprocate the object against which it impinges. (See HEART-CAM.) *B* shows a vertical bar or rod which is raised by the heart-wheel as the point of the heart ascends, and conversely, returning by gravity; keeping constantly in contact with the face of the cam.

Heat. (*Forging.*) *a.* The mass or piece of iron undergoing forging. Where it is made from the end of a rod or bar, the latter is called the *porter*, and forms the handle. When the mass is heavy, a long iron rod is welded to it in continuation of its axis. The mass is then swung from a traversing crane and is guided by the *porter-bar*.

b. A single exposure to the fire, as "to make a weld," or "to shape a horseshoe at a *single heat*."

c. Latent heat "is the heat which is absorbed by bodies in passing from one state to another, but it does not manifest itself by producing an increase of temperature, and is on this account called *latent* heat. . . . . A pound of water at 212° mixed with a pound of *water* at 32° gives two pounds of water at 122°, the mean of the two components; if, however, a pound of *ice* at 32° be mixed with a pound of water at 212°, we have two pounds of water at 51° only, ... the difference being equal to that required to raise two pounds of water through a range of 71° . . . . representing the heat required to liquefy one pound of ice." — BALFOUR STEWART'S *Treatise on Heat*.

It was discovered by Black, and was taught by him in 1762.

d. Specific heat is the quantity of heat required to raise the temperature of a body of a given weight 1°; the unit of measure being the quantity required to raise the same weight of water to the same temperature.

Degrees of heat are noted by the THERMOMETER or the PYROMETER (which see).

In practice the degree is frequently noted as *red* heat, *cherry-red*, *white* heat, *welding* heat, and so on. See FUSING-POINT.

Heat-en'gine. A thermo-dynamic engine in which motive power is produced by the development of heat. Such are steam and hot-air engines, and others which are effective by the explosion of gas, etc. See AIR-ENGINE; STEAM-ENGINE.

Heat'er. 1. A stove or furnace for warming a building, dry-house, or some portion of a machine, as a calendering apparatus in a paper-mill, etc. See list under STOVES AND HEATING-APPLIANCES.

2. A block of iron, made red-hot in a fire, and then placed in an urn or smoothing-iron.

3. A pan in which the juice of sugar-cane, or the water gathered from the maple, receives a preliminary heating before reaching the evaporating-pan.

Heat'ing-ap'pa-ra'tus. See specific list under STOVES AND HEATING APPLIANCES.

The various contrivances employed for warming buildings may be classed under: —

Methods of Warming independently of Ventilation.

1. By close stoves, the heating surface being either of iron, earthenware, or soapstone.

2. By hot-air flues, passing under the floors, or around inside the walls.

3. By a system of endless pipes heated by a current of hot water from a boiler, the circulation being caused by the cooling, and consequently greater weight, of the water in the lower or returning pipe.

4. By steam pipe and radiators.

5. By gas.

Methods of Warming combined with Ventilation.

6. By open fires placed in the several apartments.

7. By causing air, which has been previously heated, to pass through registers into the several rooms.

In the time of Seneca a large stove, or several smaller ones, was constructed in a cellar beneath the living-apartments, and the flue conducted into dining-room and bedchambers. It is probable that the plan resembled some of our green-house arrangements. It was originally used by the Romans in their baths, the *calidarium* being heated by the flues of the fire by which the warm baths were prepared. (See HYPOCAUST.) These caliducts were, no doubt, of various kinds, the architects and engineers of the Imperial City being very skillful and thorough; but it was no doubt true of Italy at that day, as it is at the present, that the provision of means for artificially heating apartments was lamentably deficient. Chimneys were almost unknown. The references to these are very scant and few. See CHIMNEY.

The Italian architect, Palladio, who wrote at A. D. 1560, thus writes of the heating arrangements of the ancient Romans: —

"The Romans were sensible that a continual flame and a great heat from live coals were hurtful to the eyes; they therefore went very wisely about finding out a remedy. They found how dangerous it was to carry fire about the house from one room to another. Stoves are an abominable invention: they cause a continual stench, swell the head, and make men drowsy, dull, and lazy. Most people that use them grow tender and weak: some cannot stir out of these rooms all the winter. The ancients used to light their fire in a small furnace under the earth. Thence they conveyed a great many tubes of different sizes into all the different stories and rooms of the house, which tubes or pipes were invisible, but laid in the thickness of the walls and ceilings, just like water-pipes. Each of these opened at that part of the furnace which joined to the wall of the house, and through these ascended the heat, which was let in whenever they had a mind it should, whether in dining-rooms, bedchambers, or closets, much in the manner as we see the heat or steam of water contained in an alembic to ascend and warm the parts most distant from the fireplace. The heat in that manner used to spread so equally that it warmed the whole house alike. It is not so with chimneys or hearths; for if you stand near, you are scorched; if at any distance, you are frozen; but here a very mild warm air spreads all around, according as the fire that warms the pipes laid along the wall opposite to the hearth is more or less burning. Those pipes which dispensed the heat did not open into the furnace itself, in order that neither smoke nor flame should get into them, but only a warm steam should enter, which they let out again; thereby creating a continual moderate heat. The fire needed not to be large, provided it was continual, to supply those confined and enclosed pipes with a sufficient power of warming. They dressed their meat at the mouth of the furnace; and all along the walls were disposed kettles, or other vessels, filled with hot water to keep the meat warm."

From this it would appear that the conduits were

Digitized by Google

actually hot-air pipes, and not flues; the heated current in the pipes proceeding from a chamber around the furnace, but not contaminated by the gaseous and sooty results of the combustion of fuel.

In the partially exhumed city of Pompeii there are some traces of the conducting of heat by pipes from the bath-room to the triclinium and other private apartments. Heating by braziers was, however, the ordinary practice when artificial heat was needed, and there are many days in the year when the climate of even Southern Italy is anything but salubrious.

The Chinese call a stove which is heated by a furnace a *kang;* in the *ti-kang* the flue runs under the floor or pavement of the room; the *kao-kang* is used for heating their sleeping and sitting places. In the *tong-kang* the heating flue is carried along the floor, with openings from it at which the heated air and smoke ascend into the spaces of a hollow wall, thus nearly approaching the principle of the chimney.

A *tong-kang* was erected in 1761 by Sir William Chambers for heating the orangery at Kew Palace, near London.

In imitation of the Chinese method, he introduced heated air through an air-pipe or flue in contact with the heating flues.

The method of obtaining warmth in Persia is by means of a large jar, called a *kourcy*, sunk in the earthen floor, generally in the middle of the room. This is filled with wood, dung, or other combustible; and when it is sufficiently charred, the mouth of the vessel is shut in with a square wooden frame, shaped like a low table, and the whole is then covered with a thick wadded quilt, under which the family, ranged around, place their knees to allow the hot vapor to insinuate itself into the folds of their clothing; or, when they desire more warmth, they recline with the quilt drawn up to their chins. The immovable position necessary for receiving the full benefit of the glowing embers is inconvenient; and the effluvia from the fuel is nauseous and deleterious. The *kourcy* also serves for an oven, and the pot is boiled on its embers. This rude and unwholesome method is adopted in the noblest mansions of the cities, as well as in the dwellings of the poorer classes; only, in the former, a more agreeable fuel is burnt, and the ladies sit from morning till night under rich draperies spread over the wooden cover.

The palace of the Khalif of Cordova, A. D. 1000, was heated by hypocausts in the vaults below, the warm and perfumed air being conducted by earthen pipes or caliducts in the walls, and discharged into the apartments.

Heating by a circulation of hot water, proceeding from a boiler and returning thereto in a comparatively cool condition, was invented by Bonnemain in 1777. (See INCUBATOR.) In 1816 a conservatory at Brompton, England, was thus warmed. See CALORIFÈRE; HOT-WATER HEATING-APPARATUS.

James Watt, in 1784, heated his study by a steam box or heater made of sheet-iron, the plates 2½ by 3½ feet and 1 inch apart. This box had an air-escape cock, a steam-induction pipe, and a water-escape. It was supplied by the boiler of the establishment.

The experiment was repeated by a system of copper pipes, under Hoyle's patent, 1791. The steam ascended to the top of the building and passed downward.

Lee of Manchester erected a heating apparatus of cast-iron pipes, which also served as supports for the floor. This was constructed by Boulton and Watt in 1799.

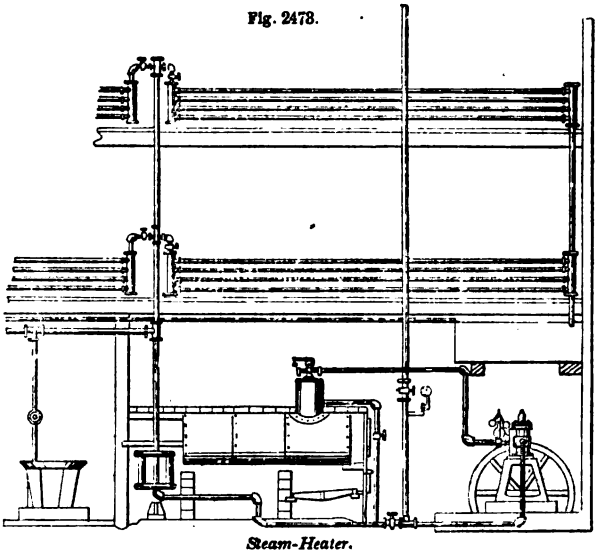
Fig. 2473 shows one form of steam-heating apparatus, in which exhaust steam from the engine is conducted to a heater back of the second fire bridge, and thence by a stand-pipe to the sets of pipes on the different stories of the building.

Gas has been used for warming, sometimes in connection with plates exposed to the jets, and sometimes has been adapted to the ordinary fireplaces where the perforated coil is disposed in a manner resembling grate-bars. Goddard's gas-heater, English, is of the latter description, and asbestus is spread over the bars so as to afford a mass of material capable of preserving incandescence, and affording radiation without consumption.

Warming apartments by hot air, as has been stated, was practiced by the Romans.

The modern mode is by a furnace in the basement story; air from the outside is admitted to a chamber around the furnace and conducted by pipes to the auditorium of, the church or to the hall and apartments as the case may be.

Fig. 2473.



Steam-Heater.

The effectiveness of the hot-air current is materially interfered with by the opening of external doors and windows, the circulation depending upon the ascent of the rarefied air.

In the Reform Club House in Pall Mall, London, the circulation is secured by a large fan rotating in a cylindrical case and driven by a steam-engine of 5-horse power in the basement. 11,000 cubic feet of air per minute are forced through a tunnel and then through a cellular steam-heater, where it acquires a temperature of from 75° to 85° Fah. From a brick chamber it passes by pipes to the various apartments, where it is admitted by dialed registers. See HOT-AIR FURNACE; VENTILATION.

Dr. Arnott calculated the quantity of heat-radiating surface necessary to warm a room in winter to 60° when the external temperature is 22°, to be a foot square of surface heated to 200° for every six

Digitized by Google

feet of glass, as much for every 120 square feet of wall or ceiling, and as much also for every six cubic feet of air escaping per minute by ventilation. See GRATE; FIREPLACE.

Heat'ing-pan. 1. A flat pan with stirrers, in which linseed meal is warmed before being bagged and pressed.

2. The first pan into which sugar-water of the maple, or the juice of the sugar-cane, is warmed before dipping or running into the evaporator.

Heat'ing-stove. The stove of Russia, Poland, and Northern Germany consists of a combustion-chamber and a number of reverting flues in which the heated current gradually parts with its caloric. The fire-chamber is surrounded by a good non-conductor of heat, and the heated products of combustion are retained within the stove as long as possible, in order to communicate the greater part of their heat to the stove, and thence to the air of the room.

This is effected by an arrangement similar to that shown at *A* (Fig. 2474), in which the lower space represents the fire-chamber, at the back of which is an upward passage *b* for the flame and smoke, which are successively diverted on their upward course by the partitions *d e f g c*, passing through their openings until discharged through the opening *h*, which is controlled by a damper.

These stoves are mounted on pillars, are made narrower toward the top, and are not placed in contact with the wall, so as to expose their whole heated surface.

In other cases they are built within partition walls, so as to heat two apartments at the same time. The fronts of these stoves are frequently quite ornamental, being built up into several stories of white porcelain in tasteful designs, and having polished brass doors.

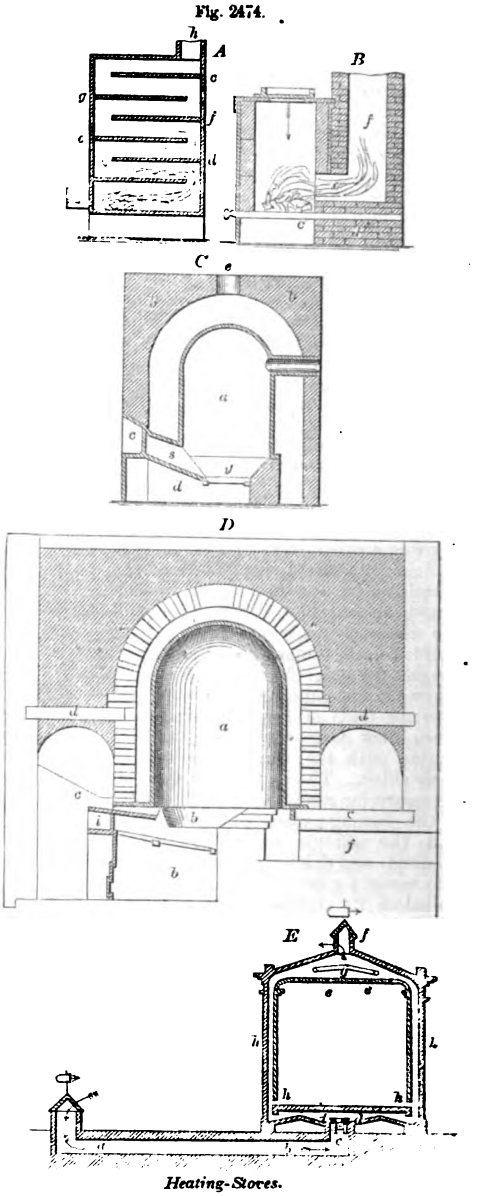
Beaumont's English stove (*B*) acts by a downward current. Two iron plates *c* are laid upon the foundation *d*, and between them is a sliding plate which covers the ash-pit. They are surmounted by a drum lined with firebrick and having a flue *x*. The drum is covered with a circular plate of cast-iron, having an opening for the admission of fuel and covered by a lid, pivoted to serve as a register. On lighting the fire this is slightly opened, and though the smoke at first tends to rise that way, the heat soon determines a downward current which deflects it through the flue *x* into the chimney *f*.

The Cockle stove *C* (Ger. *Kachel*, a tile; *Kachel-ofen*, a tile-stove), as made by Strutt, of Derby, England, has a cylindrical iron fire-chamber *a* with flat or dome-shaped head, around which is built, leaving a certain interval, a structure *b b* of brick.

The fuel is fed at *c*, sliding down the inclined plate *s* to the grate *g*. *d* is the ash-pit and draft-hole. The heated air between the stove and its casing is admitted into the room through one or more apertures *e*. This is also known as the "Belpre" stove, as the cotton-factories of the inventor in that town were warmed by it in 1792.

D is a stove erected by Sylvester for the Derby infirmary, on this principle. *c c* are the openings leading from the exterior of the building and supplying fresh air. The *cockle a* is cubical in form, and has a groined arch dome. It is made of iron plates riveted together. The smoke passes off by a narrow passage at the base of the cockle through the flue *f*. The brickwork surrounding the cockle is built with alternate openings between the bricks. Through these apertures are inserted pipes of sheet-iron, or porcelain, so as to extend within an inch of the cockle, by which means the air to be heated may be thrown near, or in immediate contact, with the surface of the cockle, if desirable. The horizontal partition *d d* cuts off the communication between the lower and the upper portion of the air-chamber, the arched openings in the lower half *c c* being the openings of the main air-flue leading from the exterior atmosphere. The fire-room

Fig. 2474.



Heating-Stoves.

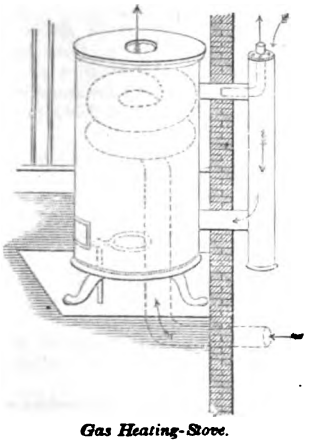
and ash-pit are shown at *b b*, and the fuel is introduced by the opening at *i*.

The air passing from the lower flues *c c* through the apertures beneath the horizontal partition, and coming in immediate contact with the surface of the cockle, finds its way into the upper air-chamber *e e* through the numerous pipes or openings of the upper division, by which circuit its velocity will be sufficiently retarded to obtain the necessary elevation of temperature from the heated cockle.

Digitized by Google

In the plan submitted by Sylvester, 1835, for warming and ventilating the Houses of Parliament (*E*, Fig. 2474), the fresh air was to be admitted through an underground channel *a b* to a cockle *c* beneath the floor of the building. It is thus heated about 15° in winter or cooled a like amount in summer. On passing through the cockle it spreads into the open space *d d*, and thence is distributed to all parts of the chamber through apertures in the floor. The ascending vitiated air, passing through openings *e e* in the ceiling, is discharged through the turn cap *f*, the opening of which is always opposite the wind. Heated pipes *g* near the roof were to insure a sufficient upward draft. When necessary to obtain a greater heat the apertures in the ceiling are closed, and the air escapes through openings in the walls *h*.

Fig. 2475.



Gas Heating-Stove.

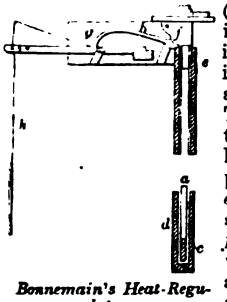
Fig. 2475 is a gas-heater. The cold air entering through the bottom is heated during its passage through the coil by annular gas-jets, and discharged into the room through the opening above. The products of combustion within the smaller drum are partly discharged through a small upward pipe, and the rest, in conjunction with a small quantity of cold air admitted through the apertures above the drum, is reverted, passing downward to aid in keeping the larger drum warm.

Heat'ing-sur'face. (*Steam-engineering.*) The fire-surface or amount of surface exposed on one side to fire and the other to water. The allowance is from 11 to 18 square feet per horse-power.

Heat'ing-tube. (*Steam.*) A water-tube in a steam-boiler surrounded by flame and connecting at each end with a water-space.

Heat-reg'u-la'tor. A device invented by Bonnemain, to keep up an equable heat in his INCUBATOR (which see). An iron rod *a* is tapped at its lower end into a brass nut *c*, inclosed in a leaden box *d*, terminated above by a brass collet *e*. The greater expansibility of the lead causes it, when the heat rises to the desired point, to elevate the collet *e*, which presses against the shorter arm of the bent lever *f g*, to the longer arm of which is connected a rod *h*, and serves to open or close a register that admits air to the fire. The instrument is provided with a dial graduated to indicate if there is an excess or deficiency of heat. See THERMOSTAT.

Fig. 2476.



Bonnemain's Heat-Regulator.

Heave. (*Nautical.*) *a.* To careen a vessel and expose the hull below the water-line, for the purpose of cleaning or repair. Known as *heaving-down* or *heeling*.

b. To haul on a rope or cable.

c. To cast the lead in sounding.

The term is frequently compounded; as, —

To *heave in stays;* to bring a ship's head to the wind. To *heave down*, to careen.

To *heave astern;* to draw the vessel aft.

To *heave and set;* to ride hard.

To *heave short;* to bring the ship above the anchor.

Heav'er. (*Nautical.*) A handspike.

Heck. 1. (*Weaving.*) A device through which the yarns pass from the warping-mill to the reel on which they are wound in order for transference to the warp-beam of the loom. The *heck-box* slides vertically on a bar as the reel rotates, and thus disposes the warp spirally on the reel.

The *heck* consists of a series of steel pins with eyes, through each of which one thread passes. The *heck* is in two parts, one a little raised from the other. The eyes of the parts being alternate, by raising one of them a little, the *bands* of the warp are separated; when the other part of the *heck* is raised, the position is reversed, the former upper band becoming the lower. This produces the *lease*, which is tied up, to form a guide for setting in the loom.

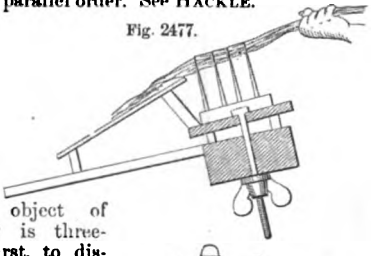
2. The *fly* of a spinning-wheel.

3. A fish-trap.

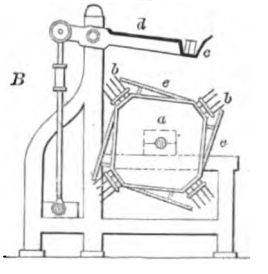
Heck-box. (*Weaving.*) A box suspended between the *travers* on which the bobbins of warp yarn are mounted, and the warping-frame on which the yarns are wound. Its duty is to divide the warp threads into two alternate sets or *leas*, one set for each *heald* or *heddle*. Also called a *jack*. See WARPING-MILL.

Heck'le. A board with sharp steel wires over which flax or hemp is combed, to clean, split, and arrange the fibers in parallel order. See HACKLE.

Fig. 2477.



The object of *heckling* is threefold: first, to disentangle and straighten the fibers; secondly, to split the wider ribbons, to lessen them and equalize their size; and, thirdly, to remove the shorter stuff from the longer, the *tow* from the *line*.



Heckle.

Heckles are of various grades of fineness, but the finer have shorter and more slender teeth; the grades are known as the *ruffer*, *common* 8, *fine* 8, 10, 12, 18; in allusion to the number of pins in a row. The pins are driven through a tin-covered board, which is clamped to the bench in a backwardly slanting position, as shown in the illustration. The bunch of flax, known as a *strick*, is thrown upon the *heckle* and drawn towards the operator, a sloping board at the back preventing its penetrating too far. One end being dressed, the *strick* is reversed in the hands of the operator, and the other end is *heckled*.

Digitized by Google

From 100 pounds of well-cleaned flax, 45 to 50 pounds of *heckled line* are obtained by hand labor of twelve hours.

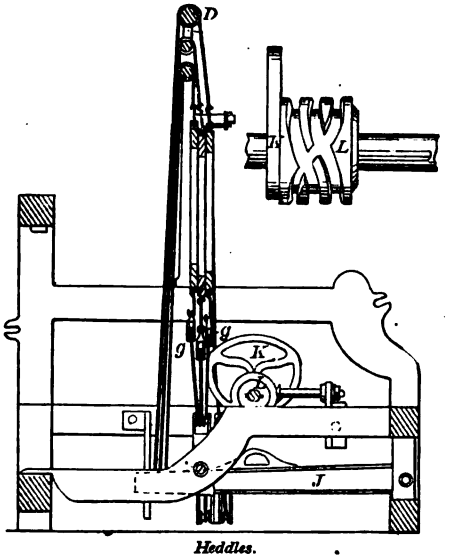
Heck'ling-ma-chine'. A machine for *heckling*, that is, separating the fibers of flax. The illustration (*B*, Fig. 2477) shows one of the earliest forms, designed to imitate the process of hand-heckling. It consists of a rotating square *a* with truncated corners, at which the heckles *b* are fixed. A *strick*, about four ounces of flax, previously slightly straightened and dressed, is fixed in the holder *c* on the arm *d*, which is oscillated while the heckle-carrier is being rotated. The separated fibers which collect on the heckles are removed by hand, and the strick, when thoroughly heckled on this, is again heckled on a similar machine with finer teeth. *e e* are back-boards limiting the depth of penetration.

A machine in which the strick of flax was made to vibrate over fixed teeth, so as to heckle the two sides at once, has also been employed.

Machines in which the strick was held over an endless band provided with heckle teeth, or drawn between two such bands, have been used to a considerable extent. The machine now in general use consists of an exterior drum, at the periphery of which are placed removable holders; this has a slow rotary motion, while rapid revolution is imparted to a toothed drum within; the flax hanging down from the holders is, when sufficiently heckled on one side by these teeth, removed, turned, and heckled on the other side.

Hed'dle. (*Weaving.*) One of the sets of parallel knotted cords forming loops for the warp-

Fig. 2478.



Heddles.

threads; and by whose vertical reciprocation the warp-threads are shifted so as to make the *shed* for the passage of the shuttle. The heddles, with their appliances for moving, constitute the harness. See HARNESS.

Heddles are a necessary integral feature of all looms, having sets of strings for separating the warp-threads into two or three groups, between which the weft is passed. This is called *mounting the loom*, and consists in dividing the warp among the *leaves of healds* or *heddles*.

In *plain weaving* but two heddles are required, which raise and depress alternate threads; but in twills the *heddles* are equal in number to the number of threads contained in the interval between two intersections of the warp and weft. In *blanket twill* every third thread is crossed. In finer fabrics the threads intersect each other at intervals of 4, 5, 6, 7, or 8 threads. In full satin twill there is an interval of 15 threads. With the Jacquard the devices rise to the highest order of merit. See JACQUARD.

In the illustration, the twilling-cam *K* depresses such one of the set of levers *J* as is beneath it for the time being. The cam *K* is attached to a circumferentially grooved hub L, which slides on the shaft *y* and is controlled in its motions by a switch, so that the motions of the heddles *g g* follow in proper sequence. The heddles are suspended by cords which pass over a roller *D* and down to the levers.

Hed'dle-eye. (*Weaving.*) The loop in a heddle through which the warp-thread is passed.

A glass ring in the eye is known as the *mail of the heddle*.

Hed'dle-hook. (*Weaving.*) A hook used in heddling the warp-threads.

Hed'dling. (*Weaving.*) Drawing the warp-threads through the *healds* or *heddles*; a weaver's harness.

Hedge-bill. (*Husbandry.*) A cutting-tool used in making stakes for repairing and for trimming hedges. See BILL-HOOK.

Hedge-clip'per. (*Husbandry.*) A favorite device for dividing land into fields, especially where lumber and stone are scarce. For obvious reasons, the thorn has always been a favorite for this purpose; Micah (vii. 4) says, "Sharper than a thorn hedge." It is yet the ordinary fence in Palestine.

The relevancy of the subject here arises from the fact that tools and machines are made for planting, training, and trimming hedges.

Thorns for hedges were used by the Greeks 1000 B. C. Homer represents Ulysses as finding Laertes digging, and preparing to plant a row of quick-sets.

"The art of clipping trees," says Pliny, "was invented by C. Martius, a friend of the late Emperor Augustus, within the last eighty years" (A. D. 79). He had not seen the beautiful gardens of Egypt.

In some of the principal apple counties of England, the hedges are made of apple and pear trees trimmed to the proper proportions. In Brecknockshire, hazel is much used; blackthorn and hawthorn are also common; the latter is more used than any other hedge shrub.

The osage-orange (*Maclura*), honey-locust, and some varieties of thorn, are used in the United States for hedges. Hawthorn is the favorite in England, but does not stand our climate. Ornamental hedges are made in this country of privet, althea, spruce, arbor vitæ, rose, and occasionally a pear or other trees and shrubs. In England, the laurel, laurustinus, arbutus, Portugal laurel, bay, and other beautiful evergreens are used, but they do not so well suit this climate.

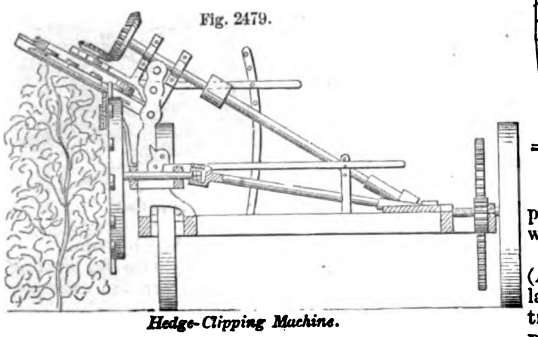
Hedges are planted in single or double rows, the latter from eight to twelve inches apart. The plants about the same, except that in single row they are at a distance of six inches. The maclura or osage-orange is the favorite, and has a great tendency to run up. It must be clipped savagely to make it spread below, allowing it an extra three inches of hight at each of the three clippings during its first year's growth. In succeeding years it may be allowed to advance about a foot a year, and at the end

Digitized by Google

of five years it should be five feet broad at bottom and five feet high, slanted on each side to a central ridge. A first-rate fence is horse-high, pig-tight, and bull-strong.

Planted in a single row, six inches apart, a mile of hedge will take 10,560 plants. A double row — the plants eight inches apart in the rows — will take 15,840 plants. A fence eight rails high, staked and double-ridered, will, for the same distance, take 7,680 rails. Board fence, five boards high and the posts six

Fig. 2479.



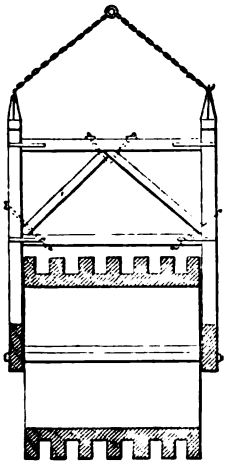
Hedge-Clipping Machine.

feet apart, will take 1,173 posts and 13,200 feet of lumber, the boards being six inches wide and one inch thick. To this latter calculation add the value of the nails; and in each mode of fencing consider the first cost of putting in order and the subsequent wear and tear, and the cost of renewal of the rail and board fences, and of clipping the hedges.

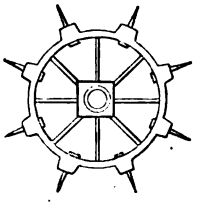
Hedge-clipping tools are usually shears (see HEDGE-SHEARS); but machines are made which pass alongside the hedge and, by their revolving cutters, trim it to the shape to which the cutting apparatus is adjusted, as in Fig. 2479.

Hedge'hog. (*Hydraulic Engineering.*) A machine attached to the stern of a steamboat or barge,

Fig. 2480.



Hedgehog.

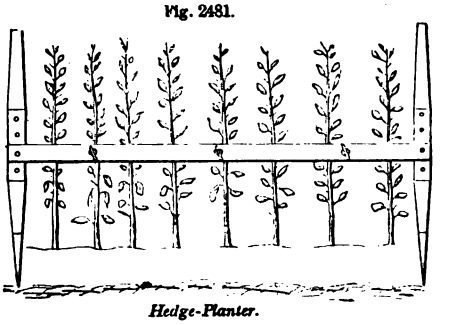


and dragged along the bottom of a river or watercourse to remove the mud or accumulation on the land side of a sluice, by raising and disturbing the mud and silt so that the current will carry it off. It consists of a frame with a revolving reel armed with shovels, which dig into the mud and spade it up as it is dragged along.

The frame is of 4 × 6 oak scantling, braced, and diagonally bolted. The spades are 4 inches wide, 7 inches long, and 7 inches apart. In some cases it is hauled by capstan and tackle, or moved by the current.

Hedge-plan'ter. (*Husbandry.*) A frame for holding plants in order as to distance and position while being set in the furrow prepared for them. The plants are clamped and supported at their

Fig. 2481.

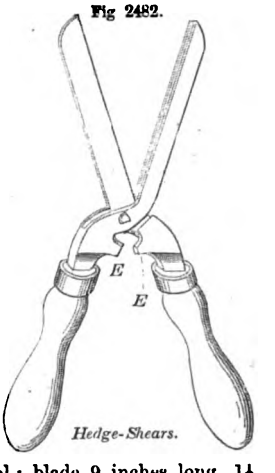


Hedge-Planter.

proper relative distance between adjustable bars which engage perforated plates in the posts.

Hedge-shears. (*Husbandry.*) A large scissors for trimming the rampant growth of hedges. In the example, the blades are for the shearing action, and a more powerful cutter *E E* is provided for stray stalks.

Fig 2482.



Hedge-Shears.

Hedg'ing-tools. (*Husbandry.*) The implements for hedging are thus enumerated by English authority. The items may be useful.

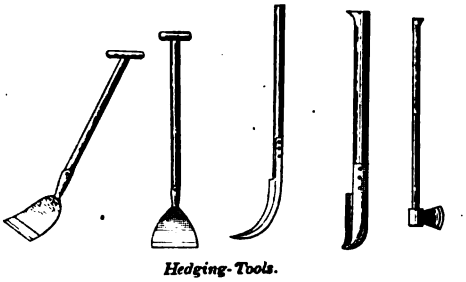
A scuffle hoe; blade 7 inches long, handle 5 feet long.

A hedging spade 3½ feet long, blade 6 inches wide.

A hooked cutting-tool; blade 9 inches long, 1½ inches broad; shaft 2½ feet long; weight, 2¼ pounds.

A heavier bill-hook for cutting stems; blade 7

Fig. 2483.



Hedging-Tools.

inches long, 2½ inches broad; handle 2½ feet long. Tool weighs 6 pounds.

A light axe weighing 3 pounds; helve 3 feet long.

Heel. A term as opposed to *toe*.

1. (*Shoemaking.*) A block built up of pieces of leather, and serving to elevate from the ground the rear portions of the boot or shoe.

Digitized by Google

Heels are usually made of several thicknesses of leather, called *lifts* or *taps*, which are fastened together and to the *insole* and *quarter* by pegs or nails.

Other materials are used for heels, such as, —

Wood.	Cast-iron.
Vulcanite.	Metal. Plated

Brass shells filled with wood.

Shell of leather, filled with composition of sawdust, waste-leather scraps, and glue or resin.

Pieced heels are made of scraps approximately fitted together in a mold having movable sides, and then compressed so as to bring them to close conjunction and the required form. See Bigelow's patent, in which the *blank-heels*, built up in readiness for attachment to the boot, are punched while in a state of compression, and have the nails partially inserted ready for the final driving which fastens them to the boot. In some cases, as a substitute for the shaved *rand*, the upper lift is made basin-shaped by compression. The punching is done by a gang of awls. See also Ellis's patent of December, 1863, reissued, for punching the lifts of boots and shoes.

After the blank-heel has been made, it is placed in the socket of a machine against the boot in position, and a plunger drives the whole gang of nails at once through the insole and counter, and clenches them against the anvil which rests on the insole of the boot. Or, nails are forced through the inner sole into the heel from within; also, from the outer or wearing surface down through the heel-lifts by means of rods arranged to pass through nail-plates.

Julius Cæsar wore high-heeled shoes to increase his apparent stature. The shoe covered the foot.

2. A term as opposed to *head*.

(*Nautical.*) *a.* The after end of a ship's keel.

b. The lower end of a spar or timber, as the heel of a *mast*, of a *boom*, of the *bowsprit*, of the *sternpost*, of the rudder, of a *shore*, of a spar when used as a *jib* or *shear-pole*, etc.

c. The lower end of a timber in a frame; the other end is the *head*.

(*Carpentry.*) The lower end or foot of a *rafter* where it rests on the wall or plate.

(*Fire-arms.*) The upper end of the butt-end of a musket when in firing position.

The tail of a gun-lock hammer.

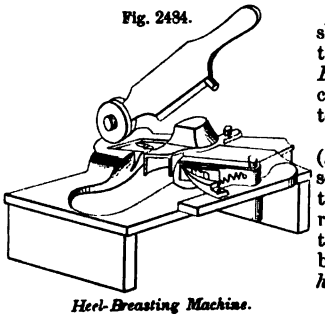
3. A lean or inclination.

(*Nautical.*) *a.* The inclination laterally of a vessel as she careens under a press of sail. Allowance for the heel is made in laying guns, a pendulum being used for the purpose.

In careening the "Royal George," 120 guns, at Spithead, 1782, to get at a water-pipe which discharged below the water-line, the vessel was sunk at her moorings.

"They made the vessel heel
And laid her on her side."

Fig. 2484.



Heel-Breasting Machine.

b. Said of a ship when deep in the water aft. *By the heel*, in contradistinction to *by the head*.

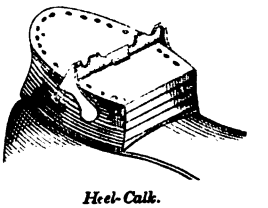
Heel-blank. (*Shoemaking.*) A set of *lifts* fastened together in readiness for attachment to a boot. A *blank heel*.

Heel-breast'ing Ma-chine'. A machine for cutting down the straight front face of a boot or shoe heel, as in the example, which has two adjustable jaws as a means of holding the heel, and a cutter and gage-plate combined with the said jaws, and a lever with pawl and rack operating on one of the jaws.

Heel-bur'nish-ing Ma-chine'. See HEEL-POLISHING MACHINE; BURNISHING-MACHINE.

Heel-calk. (*Shoemaking.*) A roughing for a heel, to prevent the slipping of the wearer on ice or slippery pavement. In the example, it consists of a strip of metal fastened to a heel by making two holes on either side of the heel. It is armed with points, and easily removable on account of its elasticity.

Fig. 2485.

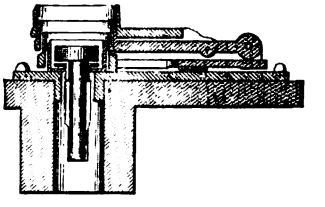


Heel-Calk.

Heel-chain. (*Nautical.*) A chain for holding out the jib-boom.

Heel-cut'ter. (*Shoemaking.*) One for cutting out the lifts which form the heel. In the example, the cutters are various in size, and are hinged to the frame, so that they can be let down over each other. The heel-lifts are cut to graduated size, and merely require beveling after attachment. The leather is placed on the cutters and forced down by blows of a wooden mallet.

Fig. 2486.



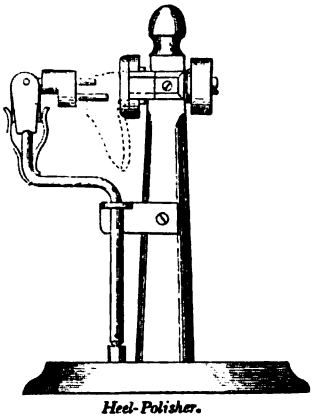
Boot-Heel Cutter.

Heel-face Dress'er. (*Shoemaking.*) One for rasping and dressing off the lower face of the heel. The boot is held by a clamp, the guides of which enter the rand, and so hold it parallel to the rotary disk-wheel which trues the face, and a burnishing-wheel which polishes the side.

Heel-i'ron. (*Shoemaking.*) A plate on the lower surface of a boot or shoe heel, to increase the durability. Sometimes put on to make a clattering, as in some fancy dances, perhaps the *cracovienne*.

Heel-ma-chine'. (*Shoemaking.*) The series of machines for this purpose are for cutting out *lifts*, or making them up of pieces and compressing them to shape; building up blank-heels by fastening together in proper order as to size the several lifts of which a heel is composed; trimming or burnishing the heels to give the required curve; *breasting*, that is, cutting down the front; cutting the seat for the heel; laying on and securing the *rands*; fastening the heels

Fig. 2487.



Heel-Polisher.

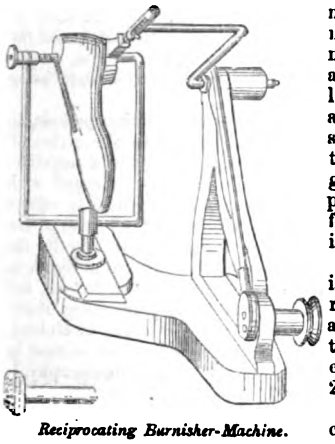
Digitized by Google

to the boots; dressing the heel-faces; polishing the heels; giving the stitch-marks on the upper surface along the edge. These operations are usually done by separate machines, and with great rapidity.

Heel-plate. The plate on the butt-end of a gun-stock.

Heel-pol'ish-ing Ma-chine'. (*Shoemaking.*) One for smoothing the surface of a heel after it is shaped and trimmed. There are several modes.

Fig 2488.



Reciprocating Burnisher-Machine.

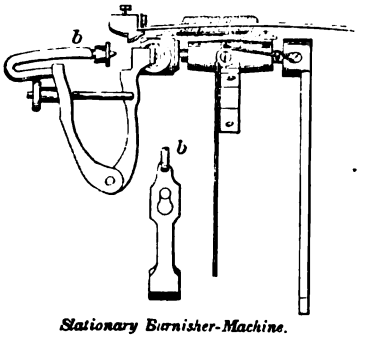
1. In the Ellis and Glidden machine, trimming and burnishing devices, actuated by a lever, move around the surface of the heel, guided by a plate having the form of the finished heel.

2. The boot is jacked and is revolved against a rotating burnisher, as in Fig. 2487.

3. The boot is clamped to the sliding frame, and the polisher reciprocated over the surface of the heel by an eccentric, whose rod is connected to the oscillating arm. (Fig. 2488.)

4. The boot is jacked, the arm *b* (Fig. 2489) reaching down the boot-leg and holding the heel to its seat. The heel is held up to the polisher, and the edge of the heel against the polisher-flange, which prevents the outer lift from spreading away at its

Fig 2489.



Stationary Burnisher-Machine.

edge while the jack is being rocked to bring the whole edge of the heel under the action of the stationary polisher.

Heel-post. 1. (*Shipbuilding.*) The post which supports the outer end of a propeller shaft.

2. That stile of a gate to which the hinges are attached.

3. The post to which a gate or door is hung.

4. The quoin-post of a lock-gate.

Heel-ring. (*Husbandry.*) The ring which is tightened by wedges and confines the scythe-blade to the snath.

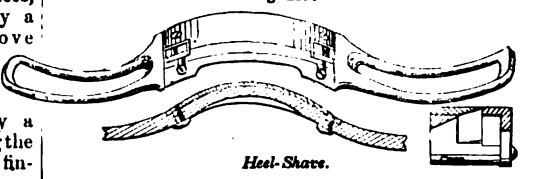
Heel-rope. (*Nautical.*) A rope for hauling on the heel of the bowsprit to run it out.

Heel-seat Cut'ter. (*Shoemaking.*) One employed to cut out the concavity in the heel to fit upon the convexity caused by the filling piece of the shank. The invention combines with a reciprocating gouge-like shank means for relative adjustment between the knife and heel-holder, adapting the same machine to cut heel-seats to fit upon different shanks.

Heel-shave. (*Shoemaking.*) A hand-tool like a *spoke-shave*, to shape the heel after the lifts of approximate shape have been fastened together.

The attaching screws of the curved blade pass

Fig. 2490



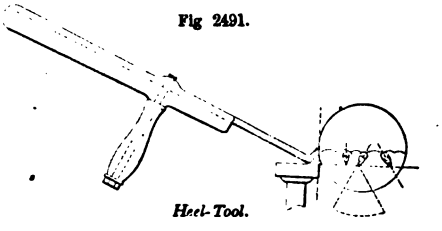
Heel-Shave.

through slots in the bridge-piece and allow adjustment of the blade. The guard-piece is removable, to admit sharpening of the blade.

Heel-tap. (*Shoemaking.*) One of the pieces or thicknesses of leather of which a heel is built. A *lift.*

Heel-tool. (*Metal-turning.*) A form of metal-turning tool in which the *heel* of the tool is supported on the rest. The helve has one piece which

Fig 2491.

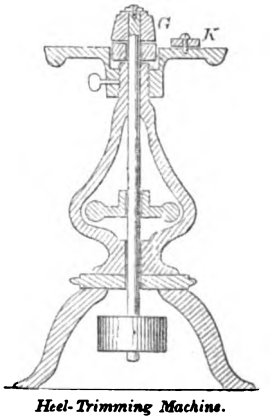


Heel-Tool.

rests on the shoulder, and a handle whereby the cutting edge is adjusted as to presentation to the work.

Heel-trim'mer. (*Shoemaking.*) *a.* A machine in which the edges of the lifts are pared down so as to bring the heel to symmetrical shape. In the example, the collar limits the depth of cut made by the bur. The adjustable table board adapts the bur cutter to the varying depths of the boot-heels, and the stud or roller steadies and supports the heel while being trimmed. The shape of the rotary cutter *G* determines the contour of the heel, which is oscillated on the roller *K* to bring each part of its surface to the cutter.

Fig 2492



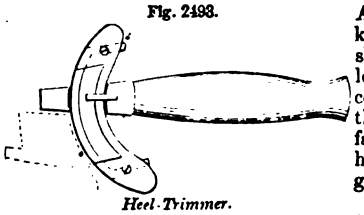
Heel-Trimming Machine.

See also HEEL-POLISHING MACHINES, which differ but slightly in construction, the principal variance being in the surface of the roller.

b. A hand-tool for shaping the curve of the heel.

Digitized by Google

Fig. 2493.



Heel-Trimmer.

A curved knife set in a shank whose lower end by contact with the lower surface of the heel forms a guide.

Heer. (*Weaving.*) The length of two cuts or *leas* of linen or woolen threads.

Hel'i-cal Spring. A spring whose coils have a gradually decreasing diameter, as the mainspring of a watch. It may lie in one plane like a fake of rope, one layer of rope as coiled up; or it may be like the architectural helix or the helix of a shell, and assume a conical form.

A spiral spring is a coil whose rounds have the same diameter.

A helical spring whose coils are in the same plane is used by alternately expanding and contracting in that plane, as with the pendulum spring and mainspring of an ordinary watch.

When the spring is more or less conical, it may be used either in the way just stated or by compression in the line of its axis.

Hel'i-co-graph. An instrument for describing helices. The small wheel rotates on the screw-shaft and revolves around the fixed point, moving towards or from the said center, according to the direction of its revolution; the pencil describing a helix, the distances between the intersections of an ordinate with the spiral are equal to the *pitch* of the screw.

Fig 2494.

Helicograph.

Hel'i-con. (*Music.*) A form of wind-instrument of metal, resembling a French-horn, but having keys and valves. They are made *en suite*, that is, of various sizes and compass. See HORN, *c.*

He'li-o-chrome. (*Photography.*) The name given by Niépce de St. Victor to the products of his process for photographing in the natural colors. A consummation devoutly to be wished, often announced with a flourish of trumpets and a new name, but not yet seen. Some indications yet afford a hope.

He'li-o-chro'mo-type. (*Photography.*) A sun-picture in the natural colors: long desired, partially obtained, but always fugitive — so far.

He'li-o-graph. (*Photography.*) 1. A sun-picture. *Heliography* is the name given to the art of taking *sun-pictures* by Nicéphore Niépce, who was the first to take a permanent picture. He used the bitumen of Judea on tin and pewter plates. He commenced in 1814, thus preceding Daguerre, who worked upon silver plates with the vapors of iodine and mercury. In 1829 they became associated, and thereafter they worked together. See PHOTOGRAPHY.

2. An instrument constructed by De la Rue for obtaining photographs of the sun. It is mounted equatorially. The image of the sun, 0.466 inches in diameter at the focus, is enlarged to nearly 4 inches by means of a secondary object-glass, and this image is received on a photographic plate. The sun's light is so intense that not only has the aperture to be cut down to 2 inches, but an instantaneous apparatus of peculiar construction has to be employed. When the picture is about to be taken, an opening, $\frac{1}{16}$ of an inch wide, flashes across the axis of the secondary object-glass, and the rays from the different parts of the disk pass through it in succession and are depicted on the collodion plate. — BRANDE.

He'li-o-graph'ic En-grav'ing. (*Photography.*) The process of Niépce de St. Victor was to coat a plate with bitumen; expose it with an engraving over it, the bitumen being, by the joint action of light and oxygen, rendered insoluble by the usual solvent. The solvent then removes the parts protected by the lines of the engraving, and the bare metal is etched by an acid.

Fox Talbot coated the plate with gelatine and bichromate of potash, and exposed it under a positive. The gelatine became insoluble where the light acted; where the film had been protected by the lines of the engraving it was washed away by water, and the lines were *bit in* by bichloride of platinum, or perchloride of iron, the other parts of the plate being protected by the film.

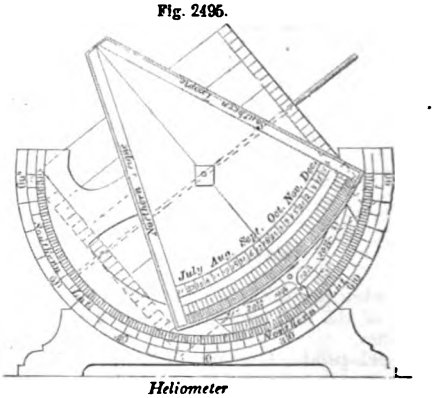
Salmon and Garnier produced another process, in which a brass plate was subjected to the action of iodine vapor and then exposed under a negative. Being then rubbed with wadding charged with globules of mercury, the latter is found to adhere only to the parts corresponding to the blacks of the negative. An ink-roller being passed over it, the amalgamated parts refuse the ink and form lights on a black ground. The variations in the process, and also those incident to the different proceedings thereafter, to fit it to be used as a copper-plate by etching, or in the manner of a lithographic stone, cannot be here detailed. See Sutton's Dict., "Photography."

He'li-om'e-ter. 1. (*Optics.*) A double object-glass micrometer (see MICROMETER), called a heliometer from its being originally used for measuring the angle subtended by the sun. The telescope, in whose field it is placed, is usually of large size and mounted equatorially; that is, having two axes of motion at right angles to each other; one parallel to the axis of the earth and the other to the equator.

The instrument was suggested by Roemer about 1678, and brought into use by Bouguer about 1748. G. Chambers credits its application or improvement to De Charmères, a French naval officer of the last century.

The object-glass is divided diametrically, and the parts are capable of motion in their own planes, and

Fig. 2496.



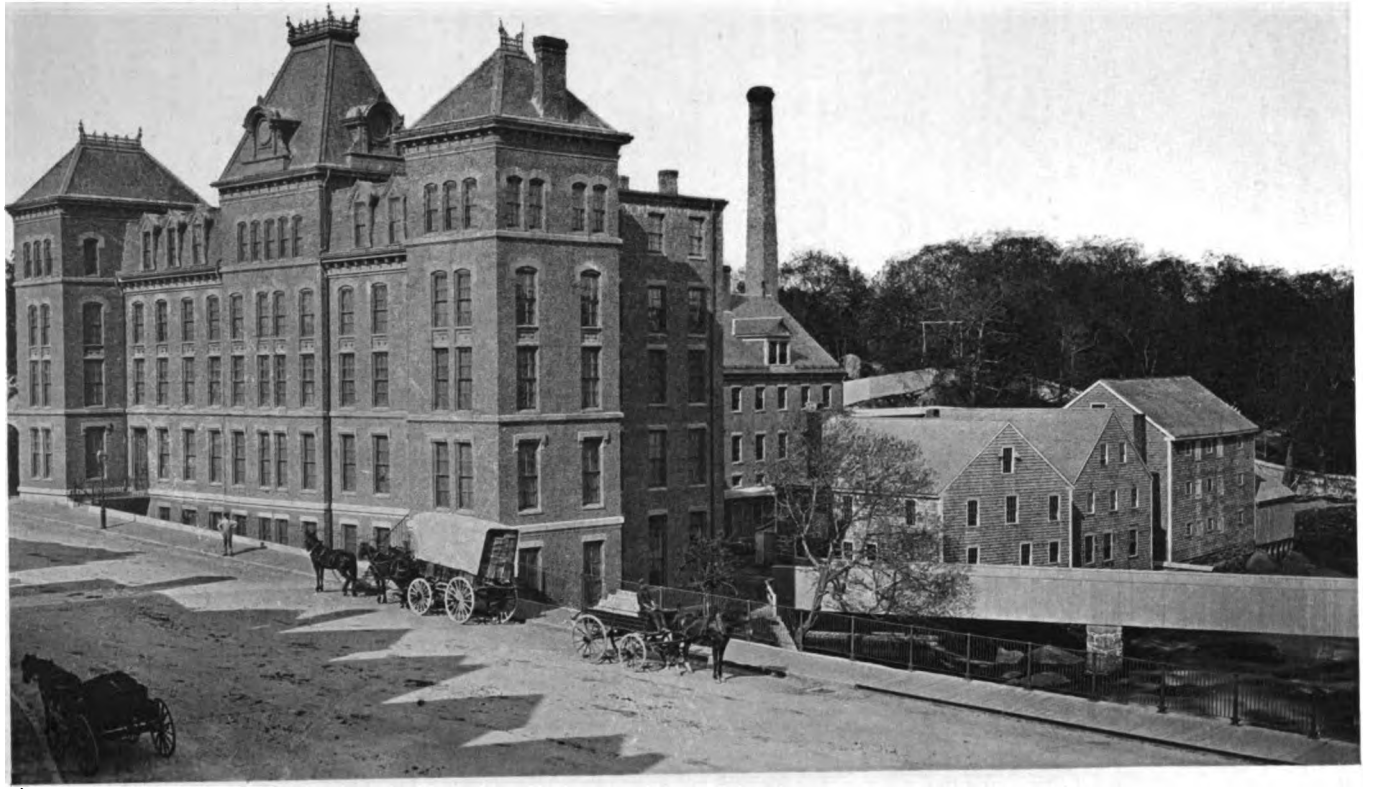
Heliometer

through considerable intervals by means of screws, and thus their optical centers can be separated. Each half-glass forming a separate image of any object, the two images will be at an angular distance, dependent on the amount of separation of the centers of the two half-glasses. Dolland called it "a *divided object-glass* micrometer."

2. A form of dial. An instrument for ascertain-

Digitized by Google

Digitized by Google



Digitized by Google

ing the solar time in all latitudes, and for ascertaining the latitude when the apparatus is set at noon according to the date. Also for ascertaining the date and length of day, sunrise and sunset, other conditions being established. Also, the differences of time between two places, the position of the earth's axis in relation to the level at the point of observation, etc. It does not admit of a brief description.

He'li-o-scope. (*Optics.*) The name given by Scheiner (1625) to an instrument of his own invention for observing the sun without hurting the eye.

Such instruments have a semi-opaque medium; shut off the greater portion of the rays; or have reflectors which transmit but a small portion of the rays.

Huyghens, in making a comparison of the intensities of the solar light and that of Sirius, employed upon the former a tube having a very small aperture at one end, into which was inserted a minute globular lens, which allowed only $\frac{1}{27664}$ part of the solar disk to be seen. He found this portion afforded a light equal to that of Sirius, and concluded that Sirius was 27,664 times more distant than the sun.

He'li-o-stat. (*Optics.*) An instrument invented by Gravesand, 1719, by which a sunbeam may be steadily directed to one spot during the whole of its diurnal period. Improved by Malus, Foucault, and Dubosq.

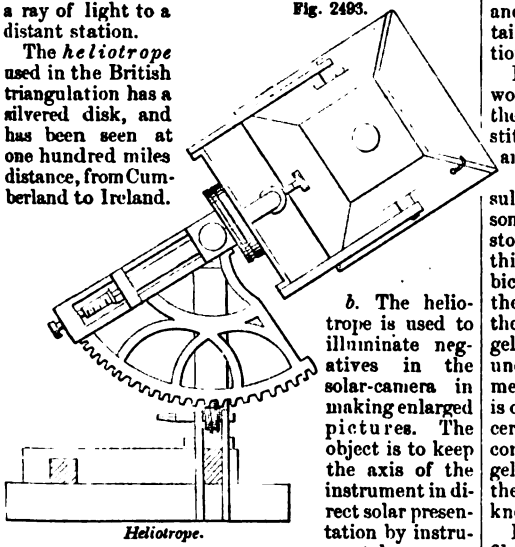
The object of the instrument is to make a sunbeam apparently stationary for purposes of experiment, obviating the inconvenience arising from the continual change of direction of the solar rays.

It consists of a plane metallic mirror, having a vertical and horizontal movement, and of a clock, the index of which moves in a plane parallel to that of the equinoctial. The extremity of the index is connected by a rod attached behind the mirror in the line of its axis. See HELIOTROPE; SOLAR-CAMERA.

He'li-o-trope. (*Optics.*) *a.* A geodetical instrument used to reflect a ray of light to a distant station.

The *heliotrope* used in the British triangulation has a silvered disk, and has been seen at one hundred miles distance, from Cumberland to Ireland.

Fig. 2493.



Heliotrope.

b. The heliotrope is used to illuminate negatives in the solar-camera in making enlarged pictures. The object is to keep the axis of the instrument in direct solar presentation by instrumental means. In the example, the optical axis of the instrument is brought parallel with the sun's rays, and kept coincident therewith by the adjustments described, a motor and a pendulum, or other time-keeper.

c. The ancient Greek *polos* or *heliotrophion* was a basin in the middle of which was a perpendicular staff or finger, whose shadow indicated on lines the twelve parts of the day; so it was a kind of dial.

He'li-o-type. (*Photography.*) Speaking generally: any process for obtaining pictures by the actinic power of the sun's rays on a prepared surface, from which to print in fatty inks. Specifically, the Edwards process developed step by step in the following way.

The action of hot water on gelatine is to dissolve it; the action of cold water is not to dissolve it, but to fill up the pores and swell it up, just as in the case of a sponge. As, after exposure to light in presence of a bichromate, hot water will no longer dissolve gelatine; so, after exposure, cold water will no longer expand it, — can no longer penetrate the pores. The light has had the effect of closing the pores, and thus rendering the gelatine water-proof. If a plate be covered with bichromated gelatine, and exposed to light under a negative, certain pores will be *completely* closed; the medium-tones will have the pores partly closed; and in the unlighted parts the condition of the gelatine will be unchanged. If this plate be steeped in cold water, some portions of it — those where light has not acted — will absorb water, and others will refuse to do so, having been water-proofed by light. On rubbing grease over the plate, the result will be that where the pores are full of water — that is, where the light has not acted — the grease will not touch the gelatine; but where the light has acted, the pores are closed, there is no water, and grease attaches itself readily; where the light has partly closed the pores, the small quantity of water absorbed does not prevent a small quantity of grease attaching itself. Lithographic ink is simply grease to which coloring matter has been added; and a lithographic roller charged with such ink, and rolled over such a plate, speedily reveals the light-produced image.

This method was discovered by Poitevin, and patented by him, as early as 1855. The process was not immediately successful, owing to the spongy and delicate nature of gelatine, the difficulty of obtaining intensity in the inking of the depressed portions, and the lack of sharpness.

Du Motay and Marechal used a very thin film in working by the Poitevin method, but failed to make the gelatine withstand the pressure. They also substituted alkaline trichromates for acid bichromates, and proposed the addition of reducing agents.

Herr Albert of Munich next produced some results by a similar method. His plan of working is somewhat as follows: instead of a lithographic stone, a glass plate is employed, of considerable thickness. On this is placed a layer of gelatine and bichromate, which, when dry, is hardened through the glass from the back, by exposure to light. On the top of this is placed a second thin coating of gelatine and bichromate; and this is exposed to light under a negative, and then hardened by chemical means. In this manner a compound printing film is obtained, having the necessary thickness to stand a certain amount of wear and tear, whilst, from its construction, the difficulty of the swelling of the gelatine is to a great extent got over; the plate is then inked and printed in the usual way. This is known as ALBERTYPE (which see.)

Edwards added to the known data, producing a film which is movable. By the addition of alum, more especially chrome alum, to the gelatine, a film can be produced consisting of a tough, tawny, insoluble substance, like leather or parchment, capable of standing an apparently unlimited amount of rough usage. Edwards discovered that gelatine might be converted into this substance, but that it still retained its property of being acted on by light in presence of a bichromate, and of receiving and

Digitized by Google

refusing greasy ink. The practice is to produce by light on a sheet of bichromatized gelatine, by means of a photographic negative, the same result that is produced in lithography by drawing on a stone with a greasy ink; that is to say, where the light has acted, just as where greasy ink has been used, water is repelled; where light has not acted water is absorbed and grease repelled, and where light has partly acted, as in the half-tones of a negative, water is partly absorbed and grease partly repelled. Ordinary gelatine is dissolved in warm water, and a sufficient quantity of *bichromate of potash* is added to render it sensitive to light, and of alum to make it very hard and durable. This is poured on a level plate, previously rubbed over with wax, and is dried in the dark by means of heat. As soon as dry, or when required for use, the sheet of gelatine is stripped from the plate, and printed under a photographic negative; the side of the gelatine which has been next the glass, and which is consequently free from dust, etc., being that on which the image is obtained. When the picture appears sufficiently plain, the sheet of gelatine is taken from under the negative, and made to adhere to a metallic plate. The method of adhesion used is that of atmospheric pressure. The sheet of gelatine and the metallic plate are put together under water; as much of the water as possible is got rid of from between the two surfaces, the gelatine absorbs the remainder so that a vacuum is created, and the picture is thus attached to the plate by the weight of the atmosphere. The superfluous chemicals are soaked out with water, and the plate, with the printing-surface of gelatine attached, is placed on an ordinary platen printing-press, and inked up with ordinary lithographic ink. As in lithography, it is necessary after every impression to damp the plate with water. A mask of paper is used to secure white margins for the prints, and the impression is then pulled and is ready for issue. Two or more inks are sometimes used in the production of one picture, as it is found that where the light has acted deeply a stiff ink is required, but where it has acted not so deeply — that is, in the half-tones — a thinner ink may be used. So that a stiff ink is first used for the shadows, and a thinner ink afterwards for the half-tones. In this manner several inks may be used in printing one impression. The effect of India or other colored tint is obtained by using, instead of ordinary water for dampening the plate, water with some color in it. The paper absorbs a certain amount of water out of the plate, and with it the desirable amount of color. The ordinary rollers are not found to be satisfactory, and a mixture of gelatine, glycerine, and castor-oil is used.

Edwards's process is worked in the United States by James R. Osgood & Co., publishers, of Boston, who own the patents.

He'lix. 1. A curve generated by winding a line around in a coil of gradually increasing radius, and maintaining the same plane; or by winding the line on a cone on which it ascends in winding.

The flat watch-spring, or the *fakes* of rope in a *tier*, are instances of the *flat helix*.

The *conical helix* is shown at *w x* (Fig. 1143), and is common as a spring in bed-bottoms and upholstery.

2. (*Architecture.*) The volute under the abacus of the Corinthian capital.

The words *helix*, *coil*, and *spiral* should not be used as if they were mere synonyms. Preferably, *coil* is the generic word, and signifies a winding; a *helix* is a flat or conical coil, as just described; a *spiral* is a coil which advances in the direction of the length of its axis, like a wire which is wound around a cylinder maintaining contact therewith throughout the length of the wire so wound, and progressing in the length of its axis; the spiral is seen in the chronometer-balance (Fig. 532) and in the car-springs *m* to *v* (Fig. 1143).

Hel-len'o-type. (*Photography.*) A picture in which two finished photographs are used. One is taken very light, the paper made translucent by varnish, tinted on the back, and laid the stronger print, so that there is a combination of effects.

Helm. (*Nautical.*) The rudder and its operative parts; such as *tiller* or *wheel*.

"The ships . . . . are . . . . turned about with a very small *helm*, whithersoever the governor listeth." — JAMES iii. 4.

When the helm is *a-starboard* the tiller is over to the right side, the helmsman looking forward.

A-port; it is to the left side.

Up; it is to the weather side.

Down; it is to the lee side.

Helm-port. The opening in the counter through which the head of the rudder passes.

Hel'met; Helm. *a.* Defensive armor for the head. *Casque*, *head-piece*, *morion*, are other names for the same thing. It was anciently formed of skins, leather, brass, iron, and still survives in the metallic and leather helmets of European armies.

Dr. Abbott's collection in New York has the helmet of Sheshonk or Shishak, with his cartouche upon it.

Herodotus states that "the Carians were the inventors of three things, the use of which was borrowed from them by the Greeks; they were the first to fasten crests on helmets, to put devices on shields, and handles on shields."

Herodotus describes (Book VII.) the following head-dresses of the nations forming the motley army of Xerxes: —

"The Assyrians had helmets of bronze or iron." Layard found some of the latter metal at Nineveh.

The Scythians had "tall, stiff caps, rising to a point." They were probably of felt.

The Ethiopians "wore upon their heads the scalps of horses, with the ears and mane attached; the ears were made to stand upright, and the mane served as a crest."

The Paphlagonians had leather helmets.

"The Thracians wore skins of foxes upon their heads."

"The Chalybes had brazen helmets, and above these they wore the ears and horns of an ox fashioned in brass. They had crests on their helms."

"The Milyæans had skull-caps of leather."

The Moschians and Colchians, wooden helmets.

The Mares had plaited leather helmets.

The Persians, soft caps.

The Lycians, hats with plumes.

Some of the Assyrian contingent wore fillets round the head, — perhaps turbans.

b. A diver's helmet is made of thin sheet-copper, furnished with eye-holes, the glass of which is protected by brass wire. It comes well down over the breast and back, and is fastened by rivets to a water-proof canvas jacket, so tightly that no water can penetrate.

To the helmet are attached the elastic tubes by which vital air is supplied to the diver and the exhausted air removed. The supply-pipe communicates above with the barrel of an air-pump, and the fresh air from above is made to impinge upon the inside surface of the glasses so as to evaporate the moisture condensed from the breath of the diver. See ARMOR, SUBMARINE DIVER'S, page 714.

Helve. 1. The handle or shaft of a chopping-tool, such as an axe, adze, or hatchet. See HANDLE.

Digitized by Google

2. A tilt-hammer, used for shingling the balls as they come from the puddling-furnace.

Helve-ham'mer. A ponderous blacksmith's hammer, tripped by the helve and oscillating on bearings. A *trip-hammer*.

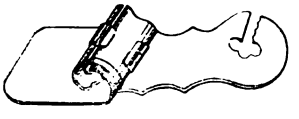
Hem'a-drom'e-ter. (*Surgical.*) An instrument for measuring the velocity of the blood in the arteries.

Hem'a-dyn'a-mom'e-ter. (*Surgical.*) An instrument for measuring the force of the current of blood in the arteries, by ascertaining the hight to which it will raise a column of mercury.

Hem'i-spheres of Mag'de-burg. Devised by Otto Güericke, 1654, to illustrate the pressure of the atmosphere. See MAGDEBURG-HEMISPHERES.

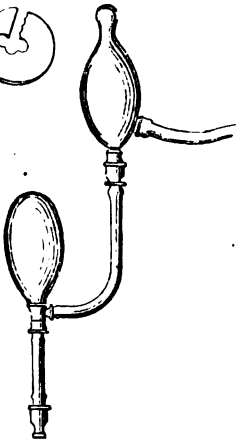
Hem'mer. An attachment to a sewing-machine for turning over the edge of a piece of fabric or a garment, in order that the flap may be stitched down. As the fabric is fed along, the edge is turned over in a curved path, and is then flattened by the presser-foot ready for stitching by the needle.

Fig. 2497.



Hemmer.

Fig. 2498.



Hemorrhoidal-Syringe.

Hem'or-rhoid'al-syr'inge. (*Surgical.*) A form of injection-syringe for the treatment of piles. In the example, the nipple on the bulb enters the rectum, and a stream of cold water is passed through the bulb, and circulates within the closed portion within the rectum.

Hemp. Hemp is not mentioned in our translation of the Hebrew Scriptures, and but sparingly in the Greek classics.

Hesiod and Homar make no mention of hemp. It is first mentioned by Herodotus: —

"Hemp grows in Scythia; it is very like flax; only it is a much coarser and taller plant; some grows wild about the country, some is produced by cultivation. The Thracians make garments of it, which closely resemble linen." — HERODOTUS, IV. 74. He elsewhere states that they buy it of the Northern people.

Hesychius says the Thracian women made sheets of hemp. The people of that country yet wear tunics of hemp, and some are employed in towing the boats on the Danube between Pesth and Vienna.

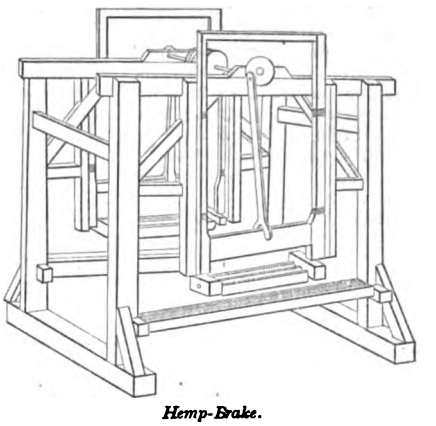
Hempen ropes were used on board the "Syracusia," built for Hiero, as recorded by Moschion. There are many other notices of hemp by later authors. It was imported in the hank or bale from the country of the *Rhodaunus*, which empties into the Vistula. The Greeks and Romans used tow for calking the seams of their vessels, but did not cultivate it before the Christian era.

Hemp was known to the Roman naturalists, but does not seem to have been used as a fiber plant. It was known to the Anglo-Saxons, and the mode of preparing and beating it is given by Strutt. Hempen cloth became common in Middle and Southern Europe in the thirteenth century.

For specific list of appliances in the treatment and manufacture of hemp and other fiber, see COTTON, FLAX, WOOL, HEMP, etc., APPLIANCES.

Hemp-brake. A machine in which rotted and subsequently dried hemp-stalks are beaten to remove the bark and cellular pith from the fiber. Among the forms of the machine may be noticed the simple sword or slats driven between two slats set edge up; the hemp is laid crossways of the slats, and is violently bent by the blow, cracking off the scale of bark and powdering the pith.

Fig. 2499.

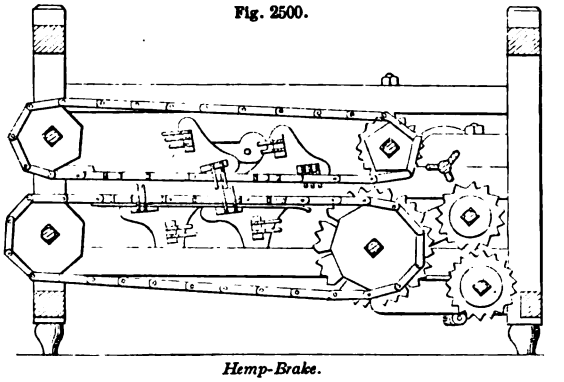


Hemp-Brake.

In Fig. 2499 the slats of the reciprocating portion and of the bed are arranged in gangs, to break the stalks which are laid crossways between them. The brake is in a gate which moves in guides by means of a pitman from a wheel above.

Other forms of brakes have rotatory motion. A series of fluted rollers whose projections interlock like cogs. Slatted interlocking cylinders. Planetary systems of fluted rollers, operating on beds of fluted rollers. In the example, the hemp is passed between braking rollers and thence is carried forward by and between endless slatted carriers, where it is broken by the action of oscillating beaters above and below, whose teeth strike it in concert between the bars of the carriers.

Fig. 2500.



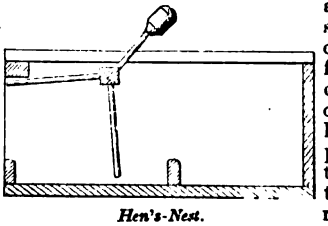
Hemp-Brake.

Digitized by Google

Hemp-har'vest-er. (*Agriculture.*) A reaping-machine for hemp. Hemp-harvesters resemble those for corn in their adaptation to operate upon tall top-heavy stalks, but as the stalk of the hemp is the valuable portion, the machine is made to cut low. One form of the machine is a puller which grasps the stalks near the ground and uproots them. Among the varieties of machines may be cited a low platform on wheels, with a cutter-bar in front, a reel to gather them to the knife and direct them over into a cradle where they are collected in a bunch. In another form, the stalks are caught by an arm till a shock is collected. In another, the stalks fall on an obliquely traversing apron which conducts them laterally and discharges them upon the ground out of the way of the horses the next time round. A stalk-puller consists of a pair of revolving disks on axes set at an obtuse angle with each other, so as to grip the stalks which are conducted between them at the lowest part of their revolution, and then open as they rotate and allow the stalks to fall into a cradle or on to the ground.

Hen's-nest. A box which furnishes a place for a fowl to lay her eggs. Contrivances have been suggested more curious than useful, and some so complicated that only well-trained hens could be expected to occupy them, and not then if in a hurry. The example has a pivoted or suspended door, counterpoised and arranged in such a manner that but one hen can enter and sit upon the nest at once. The object is to prevent hens laying eggs in the nests of setting hens, and also to prevent one hen from driving another off the nest.

Fig. 2501.



Hen's-Nest.

Her-ba'ri-um. A collection of dried plants.

Aristotle is considered the founder of the philosophy of botany, 347 B. C. The "Historia Plantarum" of Theophrastus was written about 320 B. C. Authors on botany were numerous at the close of the fifteenth century. The Botanic Gardens of Padua, Leyden, and Leipsic were established respectively in 1545, 1577, 1580; the Jardin des Plantes, in Paris, in 1624; Oxford, 1632. The system of Linnæus was made known in 1750; and Jussieu's system, founded on Tournefort's, and called the "natural system," in 1758. The latter is now accepted by such authorities as Lindley and Loudon. The Linnæan was founded upon sexual differences, the classes being determined by the number of stamens, the orders by the number of pistils. The natural system of Jussieu is founded upon modes of growth and fructification. At the death of Linnæus, the number of species described was 11,800. The number of species now recorded is probably nearly 100,000. See Loudon's "Encyclopædia of Plants," 1829.

Amateur collectors may be interested in hearing the statement of a German naturalist, that the catalogue of useful plants has risen to about 12,000, but that others will no doubt be discovered, as the researches yet made have been completed only in portions of the earth. Of these plants there are 1,350 varieties of edible fruits, berries, and seeds; 108 cereals; 37 onions; 460 vegetables and salads; 40 species of palms; 32 varieties of arrowroot; and 31 different kinds of sugars. Various drinks are obtained from 200 plants, and aromatics from 266. There are 50 substitutes for coffee, and 129 for tea. Tannin is present in 140 plants, caoutchouc in 96, gutta-percha in 7, rosin and balsamic gums in 387, wax in 10, and grease and essential oils in 330; 650 contain dyes, 48 soap, 260 weaving-fibers; 365 fibers used in paper-making; 48 give roofing-materials, and 100 are employed for hurdles and copses. In building 740 plants are used, and there are 615 poisonous plants. Some of these groups are evidently underestimated.

Her'is-son. (*Fortification.*) *a.* A beam armed with iron spikes and used as a barrier to block up a passage.

b. A barrier of the nature of a turnstile.

Her-maph'ro-dite. (*Nautical.*) A form of vessel having the forward mast and bowsprit of a brig and the after mast of a schooner, each with its proper proportions, station, rig, and sails.

Her'ni-al Sup-port'er. See Truss.

Her'ring-bone. 1. (*Masonry.*) Rows of stone or paving-blocks sloping in different directions in alternate rows. See Masonry.

2. (*Building.*) Strutting-pieces between thin joists, diagonally from the top of one to the bottom of another, to prevent lateral deflection.

3. (*Sewing.*) A cross-stitch in which the threads are laid diagonally in rows.

Her-schel'i-an Tel'e-scope. A form of reflecting telescope having no second mirror, but a speculum placed in an inclined position so as to bring the focal image near the edge of the tube, where it is viewed directly by the eye-piece, without materially interfering with the light entering the telescope from the object observed.

The magnifying power is equal to the focal length of the object-mirror divided by that of the eye-glass. See Telescope.

Herse. 1. (*Fortification.*) (From French *herse*, a harrow.) *a.* A gate with cross-bars and spiked, and serving to obstruct a passage-way, on occasion. A *portcullis.*

b. A frame with spikes, acting as a *cheval-de-frise*, to impede an advance. A *hersillon.*

c. An openwork gate which obstructs passage along a ditch or watercourse, or a sally-port traversable by boats.

2. A rectangular frame made of four bars, and having pegs on which are wound the straining strings attached to the edges of a skin which is stretched in the frame, to remove its wrinkles and hold it while being scraped. Skins for parchment are thus stretched for fleshing, scraping, and grinding. See Parchment.

Her'sil-lon. (*Fortification.*) A beam, frame, or plank set with spikes to stop a breach or way. A *herse*; a *cheval-de-frise.*

Hesp. (*Weaving.*) The length of two hanks of linen threads.

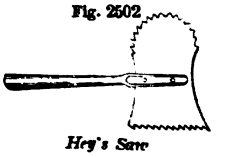
Het'e-rod'ro-mous Lev'ers. The windlass, capstan, winch, crank, crane, etc.

Hewn-stone. Stone blocks in which the faces are hammer-dressed to shape.

Hex'a-chord. A musical instrument with six strings.

Hey's Saw. A saw invented by the celebrated surgeon whose name it bears. It has one curved and one straight serrated edge. Used in making exsections, operating on the cranium, and removing carious bones from deep-seated places.

Fig. 2502.



Hey's Saw.

Hide. A flayed skin of an animal. For specific index see Leather.

Digitized by Google

The ancient Scythians made quiver-covers of the skins of the right arms of their enemies. The nails were left hanging to them. "Now the skin of a man is thick and glossy, and in whiteness surpasses almost all other hides. Some even flay the entire body of the enemy, and, stretching it upon a frame, carry it about with them wherever they ride." — HERODOTUS, IV. 64.

Cambyses killed and flayed a venal judge, afterwards cutting his skin into strips for a chair-seat, as a reminder for the son, the subsequent occupant of the chair and office. See CHAIR.

The skin of the Silenus Marsyas, flayed by Apollo, as the Phrygian story goes, was hanging in the market-place of Celænæ in the time of Herodotus. It was still shown there in Xenophon's time.

The sides of hides are the *flesh* side; and the *grain* or *hair* side.

Depilation is known as *unhairing*.

Piling is unhairing by hanging in a damp heat.

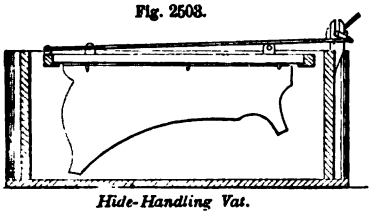
Fleshing is paring to a smooth surface by removal of fat and integuments.

Swelling is puffing it out by stuffing, etc.

Dressing embraces a number of operations in preparing the tanned hide for the use of the shoemaker, saddler, etc. See list under LEATHER.

Hide-hand'ler. A machine or vat in which

Fig. 2503.



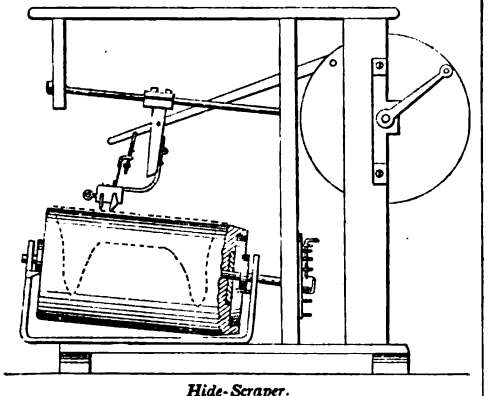
Hide-Handling Vat.

hides are moved in the liquor to expose them to the liquid in circulation, and sometimes alternately to the air and the liquor.

Hide-rope. Rope made of strands of cow-hide plaited. It is used for wheel-ropes, traces, purchase-ropes, etc. See RAWHIDE.

Hide-scrap'er. (*Leather.*) One to perform by machinery the business of scraping the flesh-side of

Fig. 2504.

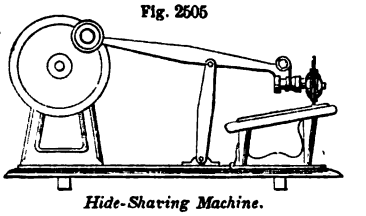


Hide-Scraper.

hides. In the example, below the reciprocating scraping-knife is a drum, upon which the hide to be scraped is secured. The drum may be vertically adjusted to the knife by means of eccentrics, and is partially rotated after each movement of the knife to bring a fresh portion of the hide into the proper position to be scraped.

Hide-shav'ing Ma-chine'. (*Leather.*) A machine having a cutting, shaving, or scraping-tool which reciprocates above an inclined table on which the hide is stretched. In the example, the tool has also a rotary motion imparted to it by means of a band.

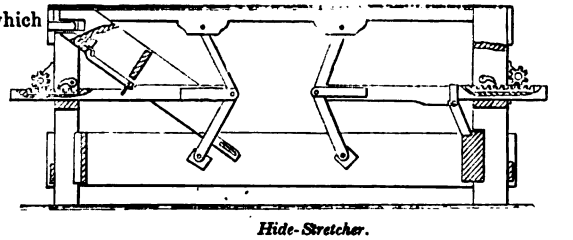
Fig. 2505



Hide-Shaving Machine.

Hide-stretch'er. (*Leather.*) A frame on which a hide is stretched to bring it to shape and remove wrinkles. In Fig. 2506, the hide is laid over a beam, and the edges of its depending sides are depressed by clamps and toggles, which are operated

Fig. 2506.

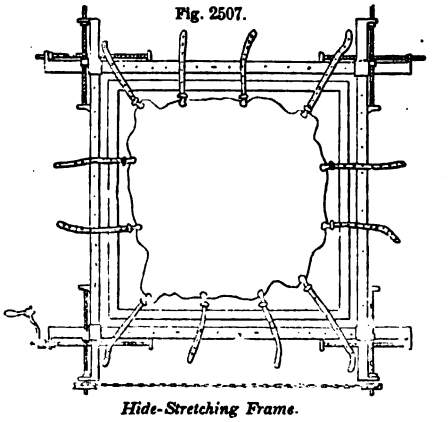


Hide-Stretcher.

by rack-bars and pinions, the adjustment of the latter being maintained by pawls.

In Fig. 2507, the pivoted nippers are tightened on the hide by the straps that suspend it within the

Fig. 2507.



Hide-Stretching Frame.

frame. The latter is expanded by screws at the corners.

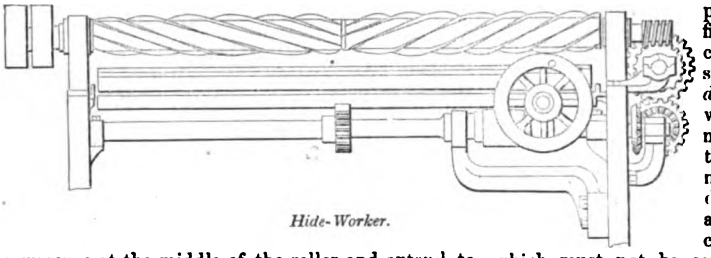
Hide-work'er. A machine for performing that part of the currying operation which consists in evening the thickness by means of knives, which, in the hand-operation, are applied to the hide while lying upon a slanting post called a *beam*. See CURRYING.

In the machine (Fig. 2508) the table moves in a frame and is covered successively with cork or vul-

Digitized by Google

canized rubber, felt, and cow-hide; it passes under a roller armed with two sets of spiral blades which

Fig. 2508.



Hide-Worker.

commence at the middle of the roller and extend to its ends.

High-fur'nace. (*Metallurgy.*) A smelting-furnace of full hight, in contradistinction to a certain smaller furnace known as the *half-high furnace.*

High-press'ure A-larm'. The object of this device, as the name indicates, is to give notice and prevent an explosion of a steam-generator. It consists mainly of two classes: 1. Fusible plugs in the side of the boiler, which give way when a certain heat is attained, and allow the steam to escape. 2. Valves which open when the pressure becomes excessive, and allow exit to steam, which blows an alarm-whistle. The first depend upon temperature, the second upon pressure. Pressure and temperature bear a certain ratio to each other.

1. Asheroft's patents of March 19, 1850, and February 18, 1851, refer to methods for the protection and insulation of the plug which is destined to give way at a certain temperature and relieve the boiler.

The patent of C. Evans, May 8, 1834, describes the use and operation of the fusible plug, which is composed usually of lead and tin, with the addition, in some cases, of bismuth. The ingredients are so proportioned as to melt at the heat at which it is desired that notice shall be given. It is used as a low-water detector, as well as to indicate high pressure, and for protection of the boiler may be placed at that portion which is most likely to be unduly heated when the water is low. See FUSIBLE ALLOYS, p. 62.

2. The alarms acting by pressure are of the nature of the *safety-valve;* the noise of the escaping steam or its impingement upon a whistle causing an audible alarm. See LOW-WATER ALARM; SAFETY-VALVE.

High-press'ure En'gine. (*Steam.*) A steam-engine, condensing or non-condensing, in which the safety-valve is loaded with a weight equivalent to a boiler-pressure of, say, fifty pounds to the square inch. In England, above twenty-five pounds to the square inch is sometimes considered as *high* pressure. This is but an indefinite definition, but customs vary. Low-pressure engines are usually *condensing,* high-pressure engines on locomotives, saw-mills of moderate size, and Western steamboats, are *non-condensing;* but the question of condensing is not necessarily one of pressure. Things took their names early, and it is not easy to bring modern forms under an old nomenclature. All the engines of Newcomen and the early ones of Watt were single-acting and condensing, and steam much over a temperature of 212° Fah. was considered high pressure; the use of steam being merely to expel the air from below the piston, in order that the atmospheric pressure may be availed when the steam is condensed. This was all the use of steam in the Newcomen period and the early patents of Watt, which concerned the separate condenser, parallel motion, four-way cock, puppet-valves, and some other features of the engine now known as the CORNISH (which see). Watt subsequently used actual pressure of steam, was the first to use it expansively by cutting off at a part of the stroke, and also invented *double*-action engines in which the steam was admitted to alternate sides of the piston, making both motions effective. He made drawings for this in 1774, and exhibited it in 1782. He called it a "double-engine," which must not be confounded with the double-cylinder engine of Hornblower of Penryhn, patented in 1781, revived by Woolf, and much improved by Worthington. See plate opposite page 763.

Oliver Evans of Philadelphia has hardly had sufficient credit for his part in the matter, but he struggled for many years to make his townsmen believe that the high-pressure, double-acting engine was to be the engine of the future, both on roads and boats. He was active in the running of his hobby from 1787 to 1803, and in the former year obtained a patent from the State of Maryland for steam-carriages on common roads. His townsmen thought him crazy, and he could obtain no patent in Pennsylvania. He exhibited his engine running in 1803, sawing wood and stone, and grinding plaster. He put it on wheels and made it move itself to the Schuylkill, put it on board a scow, and made it drive a stern-wheel, working down the river to the junction with the Delaware, and then up the latter to the city of brotherly love but weak faith. This was some years before Fulton. He had no backers, and, having spent all his money, he, at the age of fifty, turned his excellent talents into a more lucrative channel, and was rewarded with success in business. He does not seem to have been such a fretful genius as Fitch and some others of his contemporary inventors; his portrait shows a comfortable and genial man, who retired from the unequal contest before he lost his own self-respect and became a bore. "The time" was "out of joint," and he could not convince the folks against their will. Seventy years afterward the "Pennsylvania" steamed down the river, but the intervening time might count for centuries if measured by the progress made. It may be remarked that Evans used a cylindrical flue-boiler.

Next, perhaps, we should state the work of the man who has done more than any other one man to make the locomotive what it is: Richard Trevethick of Merthyr Tydvil, in South Wales. He had not got over the idea of the necessity for something more than the weight of the engine to give tractional adherence to the rails, and used a cog-wheel and rack rail. (See LOCOMOTIVE.) He used a blast of exhaust steam in the chimney, patented his locomotive in 1802, and it was in use on the Merthyr Tydvil Railway in 1804.

Trevethick and Vivian patented the application of high-pressure steam to engines. Trevethick is described in the Catalogue of the South Kensington Museum, London, as "the inventor and constructor of the first high-pressure steam-engine, and of the first steam-carriage used in England." Blackett improved on Trevethick, and used smooth wheels on a plate-way.

The multitubular boiler is stated to have been used by Rumsey, and subsequently, in 1790, in England. It was used by John Cox Stevens of New Jersey,

Digitized by Google

1791–1807; English patent, May 31, 1805. He used a Watt engine, cylinder 4½ inches diameter, 9 inches stroke. Boiler 2 feet long, 15 inches wide, and 12 inches high, with 81 copper tubes 1 inch in diameter. Boat, 25 feet long, 5 feet beam; tried in May, 1804; velocity, 4 to 8 miles per hour.

Not desiring to anticipate what should be said under LOCOMOTIVE and STEAMBOAT, suffice it to say that William Hadley's locomotive "Puffing Billy" was built in 1813, and had a long career of usefulness. Stephenson's first locomotive was built after seeing Trevethick's, as improved by Blackett for Lord Ravensworth's colliery, in 1814, and had grooved sheaves to increase adherence. Locomotives on Stephenson's plan were used on the Stockton and Darlington Railway, opened in 1825. Stephenson's "Rocket" was successful over three other competitors in the trial on the rails of the Liverpool and Manchester Railway, 1829. It used the multitubular boiler by the suggestion of Mr. Booth of that railway company, also the exhaust-blast in the chimney, invented by Trevethick. Hackworth's "Sanspareil" had a cylindrical flue-boiler on the Evans plan, and a very effective exhaust-blast in chimney. The "Rocket's" competitors broke down at various points in the trial. Stephenson was an excellent workman. The very insincere book called the "Life of Stephenson" ignores most of these facts, and pettifogs the whole case; it is about as one-sided an affair as Abbott's Life of Saint Napoleon, but has done much less harm, as it is only ungenerous and unfair, and does not debauch the judgment of the rising generation.

High-re-lief'. The projection of a sculptured figure, half or more, from the plane surface. Called also *alto-rilievo*. See RILIEVO.

Hight. 1. (*Hydraulic Engineering.*) The *fall* of a body of water. The *head*.

2. (*Shipwrighting.*) The distance between decks.

Hight-board. (*Carpentry.*) A carpenter's gage for *tread* and risers of a wooden stairway.

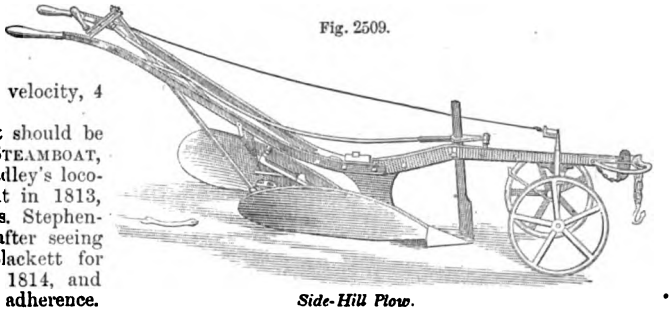
Hight-staff. (*Shipbuilding.*) A rod having marked upon it the hights above the keel of all the frames at the beam-line of the ship.

High-warp Loom. (*Weaving.*) A tapestry loom in which the warp-frame is vertical and the weaver works standing, thus being able to constantly inspect his work as it proceeds, an advantage which he does not possess in the *basse-lisse* or low-warp tapestry loom in which the warp is horizontal.

Hill'o-type. (*Photography.*) A process invented by L. L. Hill, of Westkill, New York, and much debated in the photographic journals of twenty years ago and since. He claimed — see "Photographic Art-Journal," October, 1852 — to have discovered "a method of heliotyping the colors of objects truthfully, brilliantly, and imperishably." The correspondence is voluminous, some of it acrimonious; the colors certified to have been produced heliotypically in the pictures are rosy, red, blue, green, orange, violet, buff. The process is not explained in these articles. Niépce worked long at this object, and called the products *heliochromes*. And yet we wait.

Hill'side-plow. (*Husbandry.*) One which has a turning share, so as to plow on side-hill or sidling places, returning in the last-made furrow and throwing down hill each way. The plow shown in the example is turned at the headland or end of the furrow, and by the movement of a lever the share is turned over and one *breast* is put into its proper position for work while the other is raised and carried clear on the land-side. The colter is moved by a separate lever. Such plows in England are called *turn-wrest* plows.

Fig. 2509.



Side-Hill Plow.

Hind-car'riage. (*Vehicle.*) The rear part of the running-gears of a four-wheeled vehicle. The hind wheels and axle, with or without the coupling.

Hinge. A means of connecting a door, casement, or leaf, with its frame or an object, so that it will swing thereon.

The ancient Egyptian hinges were crude affairs, and were similar in construction to those made in our early Western log-cabins. A pin projecting from the upper edge of the door was socketed in a vertical hole made in a bracket attached to the wall, and a similar pin on the lower edge of the door was stepped into a socket in the floor or threshold. The illustration *a* (Fig. 2510) is from a model house found by Mr. Salt in Egypt, and now in the British Museum. When found, it contained a supply of grain in the little store-room, but this was eaten by a rat when the model was at the Lazaretto in Leghorn, on the route for England. The grain remained in apparent good order for over 3,000 years, and was then consumed by a modern rat while the little house was in quarantine. The doors of Egypt were either single or double, and were secured by bars and bolts, as seen in the figure. The hinge-pieces were made of bronze in many cases. The accompanying figures *b c* show the upper and lower door-pins and the sockets in which the edge of the door is received, and in which it is secured by bronze pins. The projection on the upper piece was to keep the door from striking against the wall.

o shows the general form of a door in remains of stone, marble, wood, and bronze. *p* is a bronze hinge in the Egyptian collection of the British Museum. *q* is the plan of the threshold of an ancient temple with the arrangement of the folding-doors. *r s* are four Roman hinges of bronze now in the British Museum.

The term *cardo* (Lat.), a pivot or hinge, was applied to the North and South poles, on which the earth was supposed to turn. *East* and *West* being added, made the *quatuor cardines orbis terrarum*, the term yet surviving in our *cardinal points*.

Several bronze hinges, remains of ancient Egypt, are in the British Museum. One of them is 7 inches high and 11 inches long. The basalt socket of the lower one is also in the same museum. They are from the granite sanctuary of the great temple of Karnak.

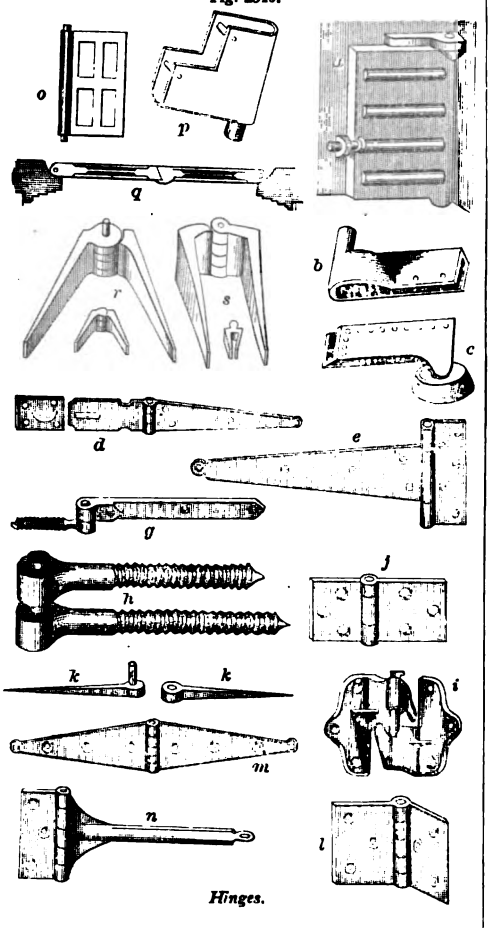
The doors of the temple of Solomon had hinges of gold. The temple seems to have been remarkable rather for lavish expenditure of gold and ornaments than for architectural beauty. Of the contemporary styles, the Egyptian and Doric, the former is the more likely to have been copied, as the Israelites

Digitized by Google

are not supposed to have originated any. They had been for several centuries in a state of transition from a nomadic to a settled life. The popular representations of the Corinthian order in the temple are anachronisms, for the temple was built 560 years before Callimachus.

There are several beautiful examples of hinge constructors in the natural world. Among them we may cite the mason-spider of the tropics and of Southern Europe. The subterranean cell of this animal is tapestried with silk and closed by an earth-

Fig. 2510.



Hinges.

kneaded door, hung upon a silken hinge and self-closing with an elastic spring, after each entrance and exit of the cavern's occupant.

Hinges are known by purpose, as, —

Blind-hinge (*i*).	Gate-hinge (*g h k*).
Carriage-hinge.	Hasp-hinge (*d*).
Chest-hinge.	Reaper-hinge.
Door-hinge.	Table-hinge (*j*).

Or by some structural peculiarity or shape, as, —

Back-flap hinge.	Screw and strap (*g*).
Butt-hinge (*l*).	Screw hook and eye (*h*).
Cross-garnet hinge (*n*).	Self-shutting hinge (*i*).
Dovetail-hinge.	Spring-hinge.
Hook and eye (*k k*).	Strap-hinge (*m*).
Loose-joint hinge (*i*).	T-hinge (*c*).

The *knuckle* receives the pin.

The leaves are *straps*.

The *rising* hinge has a spiral groove winding round the knuckle so as to lift the door when it is swung open, and thus clear the carpet.

Hinge-joint. A junction of parts allowing a flexure and extension in a certain plane. The parts are usually connected by a pintle or ligature.

Hinge-mak'ing Ma-chine'. In the Evrard and Boyer machine the sheet-metal is placed in the machine in coils, there being two coils of sheet-brass for the two halves of the hinge-body, and a coil of wire to supply the connecting bolt or rivet. The material is drawn off from the coils as it is wanted, the wings of the hinge are stamped out by punching dies to the proper shape, the salient parts, which are to form the tube for the connecting bolt, are formed upon the wire itself which is to furnish the bolt, and this is then cut off to the proper length. Before the hinge is dismissed, the screw-holes, by which it is to be secured to the wood, are formed and countersunk to the form of the screw-head. The machine completes a hinge every second.

Butt-hinges are usually molded on *match-plates*.

Hink. (*Agriculture.*) A reaping-hook.

Hip. (*Building.*) 1. The external angle formed by the meeting sides of a roof.

2. A truncated gable. See HIP-ROOF.

3. A timber which forms the angle of a hipped roof, and against which the rafters are laid.

Hip-knob. (*Building.*) The finial at the apex of a gable, or on the top of the hips of a roof.

Hip-poc'ra-tes Sleeve. A strainer bag made by folding a square of flannel diagonally, and sewing it along the meeting edge, so as to make it of a funnel shape. Or, —

By uniting the opposite angles of a square piece of cloth.

Hip-raft'er. (*Carpentry.*) The rafter at the angle of a roof. Its two outer edges are sloped to range with the rafters on each side of the roof.

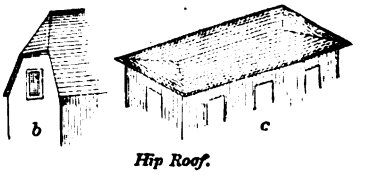
Hip-roof. (*Roof.*) An obtuse angle formed by the meeting of two portions of a roof of different slant, as in the case of a *Mansard*, *curb*, or *French* roof. See CURB-ROOF.

Fig. 2511.

A short portion of a roof over a truncated gable, as at *a*, *b*.

One having a double slope (*c*), the rafters at the exterior angles being in two pieces, meeting at an obtuse angle.

Hip-strap. (*Harness.*) One (*E E*) which crosses the buttocks of a horse and supports the breeching *B*, or the traces merely, according to the style of harness. It gives the name to one form of harness, called hip-strap harness, having no *breeching*. It is used for lead harness, in which the horses are not



Hip Roof.

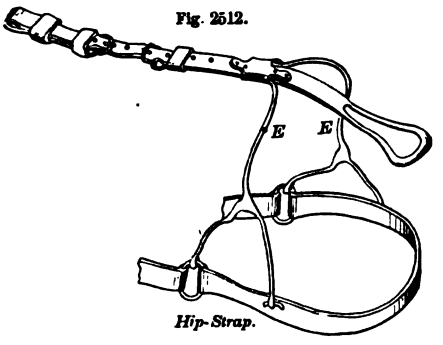
Fig. 2512.



Hip-Strap.

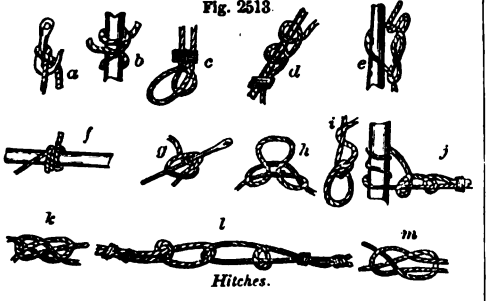
called on to hold back in descending hills, or to back the wagon.

Hip-tile. (*Roofing.*) A saddle-shaped tile to cover a hip. A *corner tile.*

Hirst-frame. (*Forging.*) The frame of a tilt-hammer.

Hitch. 1. (*Nautical.*) A species of knot by

Fig. 2513.



Hitches.

which a rope is bent to a spar or to another rope. There are various kinds knows as : —

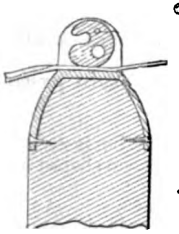
a, Blackwall-hitch.	*h*, harness-hitch.
b, clove-hitch.	*i*, midshipman's-hitch.
c, half-hitch.	*j*, rolling-hitch.
d, two half-hitches.	*k*, carrick-bend.
e, timber-hitch.	*l*, hawser-bend.
f, magnus-hitch.	*m*, sheet-bend.
g, marlinspike-hitch.	

2. (*Mining.*) A small slip where the dislocation does not exceed the thickness of the vein.

Hitch'er. (*Nautical.*) A boat-hook.

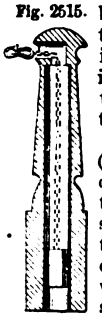
Hitch'ing-clamp. (*Menage.*) A device for holding the strap of a bridle or halter. In the example, the strap is held beneath a turning cam, so as to bind the tighter the harder the horse pulls upon it.

Fig. 2514.



Hitching-Clamp.

Fig. 2515.



Hitching-Post.

Hitch'ing-post. (*Menage.*) A post with convenient means for the attachment of the strap of a horse's halter or bridle. In the example, it has a weight to take up the slack, but allows a certain freedom of motion, as the weighted tie-chain travels in the hollow post. The weight forms a stop to arrest the extraction of the chain from the post.

Hive. (*Husbandry.*) A box or basket for a swarm of bees to live in. See BEEHIVE ; APIARY.

Hoard ; Hoard'ing. (*Building.*) A temporary screen of boards enclosing a building-site, where erections or repairs are proceeding.

Hob. 1. The flat, iron shelf at the side of a grate.

2. A hardened, threaded spindle, by which a comb or chasing-tool may be cut. A *hub.*

Hob'by. The old English name of the velocipede. "Every one rides his own hobby."

Ho'bit. (*Ordnance.*) An old form of mortar of six or eight inches' bore, mounted on a carriage.

Hob'nail. A short, thick nail, with a pointed tang, a large head, and with pendent claws, which pierce the boot-sole.

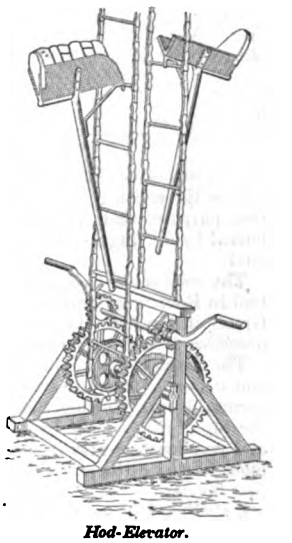
The *caliga*, or coarse shoe, of the Roman soldier, was thickly studded with hobnails.

Hod. (*Bricklaying.*) 1. A box with two sides and an end, set on edge, and with a handle by which it is carried, a padded cushion resting on the shoulder.

2. A coal scuttle or box. A coal-hod.

Hod-el'e-va'tor. A hoisting device to raise hods loaded with bricks or mortar to the building hight on a building, and return the empty ones. In the illustration, it is a traveling ladder which runs over a drum above, — not shown, — and is driven by a winch below. The hods are hooked on to the rounds.

Fig. 2516.



Hod-Elevator.

Ho-dom'e-ter. A way-measurer. See ODOMETER.

Hoe. 1. (*Agriculture.*) A tool with a flat, thin blade used to cut weeds or stir the earth around plants. In its ordinary sense, it is the familiar tool attached at a convenient angle to a straight handle, and whose duty is defined above. In England, hoes are attached to machines, but the function remains the same, for the hoes follow in the balks between the rows of plants. The same devices are here denominated *shares.*

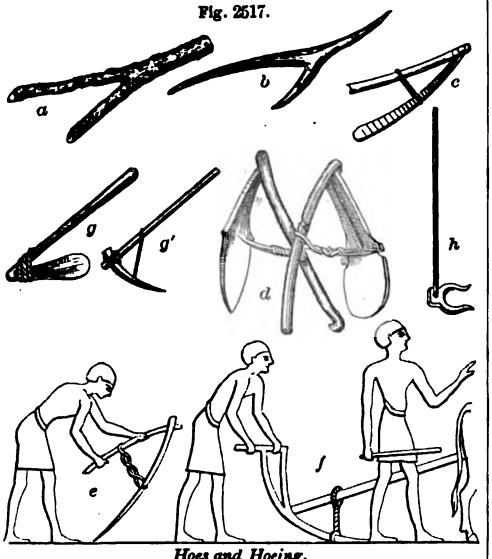
The hoe may be fairly assumed to have been the first implement of the husbandman, in its form of a pointed stick for stirring around the roots of a plant. Next comes the crotch *a* sharpened to a point, as at *b*, in which form it might be used as a hoe or plow, according to size. *c d e* represent the hoes used by the ancient Egyptians, the two former being drawn from actual hoes which have been preserved in the tombs, and the latter (*e*) being a copy of a picture at Beni Hassan. Their hoes were made of wood, the handle was about three feet long, the blade being mortised thereto at the junction and bound by a twisted rope or thong, as clearly shown in *d*, which represents two hoes in the Berlin collection. One is also to be seen in the Abbott collection, New York. *f* shows the Egyptian plow, and is introduced to exhibit the similarity in shape of the hoes *b c* and plow

Digitized by Google

f, a crotch of a tree being the original of each. The team being hitched to the long end of the crotch *b*, the shorter end forms a share or tusk, and the back portion projects for a handle. See PLOW.

With their wooden hoes the peasants of Egypt covered the seed which was scattered broadcast over

Fig. 2517.



Hoes and Hoeing.

the surface of the land yet glistening with the mud left by the retiring Nile. Plows were also used for this purpose, and not unfrequently the seed was buried by driving herds of sheep or goats over the land.

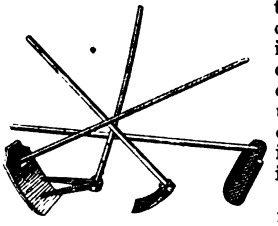
The *bidens* or two-pronged hoe was a common tool in Roman agriculture. It was also common in Greece in the form shown at *h* (Fig. 2517). Homer describes Laertes as hoeing when found by Ulysses.

The Romans hoed their grain crops, wheat, spelt, and barley. Once in early winter, a second time in spring, before jointing. The wheat was sowed on the top of ridges made by a double mold-board plow, and was consequently in rows. It was not uncommon to hoe up the earth to the young plant at the first hoeing.

g g' (Fig. 2517) are the hoes of Pacific coast Indians. *g* is a scapula; *g'* a walrus tooth.

Fig. 2518 shows four Japanese hoes in the collection of the Smithsonian Institution, Washington. The clumsiness of the two larger ones is something fearful to contemplate. The hoe or mattock is the usual implement for cultivating the land in Japan. The plow is also used.

Fig. 2518.



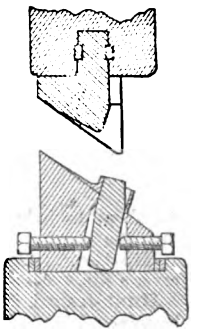
Japanese Hoes.

The hoes of Polynesia, when first discovered, were the shells of the oyster or a large kind of *pinna;* a bone from the back of a turtle; or a plate of tortoise-shell. The hoe was used with a thrust motion, like our Dutch hoe.

The hoe of the Fegee-Islanders is a blade of tortoise-shell or the valve of a large oyster. These may be considered a type of maritime substitutes for metal. Obsidian, flint, hard wood, and various other substitutes have been employed, the latter by the ancient Egyptians.

The Feejees are very ingenious in finding substitutes for metal. A hard stone ground to an edge forms an axe. A blade of tortoise-shell attached to a handle is their knife. The spines of echini are their boring-tools. Rats' teeth set in wood are gravers and chisels. The mushroom coral answers for a file, and pumice-stone for sand-paper. The axes and hatchets of America, and the knives and chisels of England, are fast superseding their primitive tools. They can now cut up their *bakolo* or long-pig — as they term the edible human body — with more civilized implements.

Fig. 2519.



Hoe-Swage.

The broad and thin metallic blade is quite a modern contrivance, and was never well made until made in the United States. It is now a scientific tool, sharp, light, and shiny. Hoes should be selected for covering or cutting; the latter have a less angle with the handle. Clean your hoes always before putting them away, and you may always resume your work in good-humor.

Hoes were formerly made by forging, but now they are more often cut out as blanks and then struck in dies.

The blade being extended and the eye formed by hand, the heated blank is placed on the anvil and secured with the pin; the drop being released falls thereon, shaping and finishing the face of the hoe.

Hoes are made in specific forms for various purposes.

a is a hoe for marking out fine drills.

b a hoe for marking small ridges.

c a hoe for working two sides of small plants.

d a hoe for drawing a pair of parallel ridges.

e a combined hoe and rake, a very common implement in the Netherlands, and used in the United States by amateur gardeners.

f has a serrated blade; *g* a sectional one.

h i j k are *Dutch* hoes, known as *scuffle* or *thrust* hoes, operated by pushing instead of striking or pulling. They are useful in extirpating weeds under bushes, and loosening the soil around growing plants.

l shows a mode of attaching the blade to the tang.

m of wedging it in a ferrule.

n o have means of adjusting the angular presentation of the blade.

p has a reversible blade.

2. (*Dentistry.*) A dentist's excavating instrument, having a blade attached to a shank and shaped like a miniature hoe.

Hoe'ing Ma-chine'. (*Agriculture.*) An implement for tending drilled or dibbled crops. It was invented by Jethro Tull, the introducer of the system of drilled crops into England, and was designed to diminish the expense of cultivation by substituting horse labor.

Tull's implement was comparatively rude, and it was successively improved by a number of inventors, among whom we notice the names of Blackie, the

Digitized by Google

two Wilkies, Weir, Hayward, Grant, Ganett, Howard, and others in Britain.

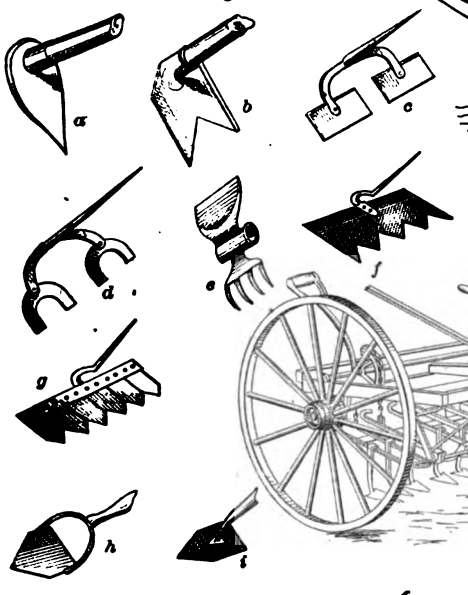
The history merges into the history of *cultivators*, in the United States our husbandry being different.

The great breadth planted to corn and cotton, and the necessity for frequent plowings, have given a different form to the tool, as the distance between the rows renders it convenient for the horse, implement, and man to follow the balk, going twice in a row, tending the crop to his right hand each time. This is very different from the hoeing of wheat, and also from the hoeing of turnips.

The horse-hoes (*b*) of Britain have a range of shares spaced like the drills, so as to work in the intervals between the rows of plants, such as wheat and turnips. Others of their horse-hoes are for the culture of plants requiring a greater width, such as mangel-wurzel, cabbages, and beans.

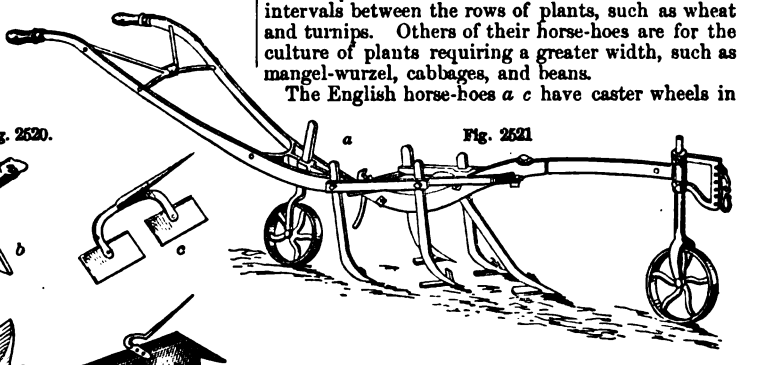
The English horse-hoes *a c* have caster wheels in front and rear, a broad middle share, and two or more side shares. The rear share may be curved or flat, as shown at *c* and *a* respectively. It is what we should call a cultivator, but there is more of it than we regard convenient. If the tool be well proportioned, and the animal hitched to it rightly, it

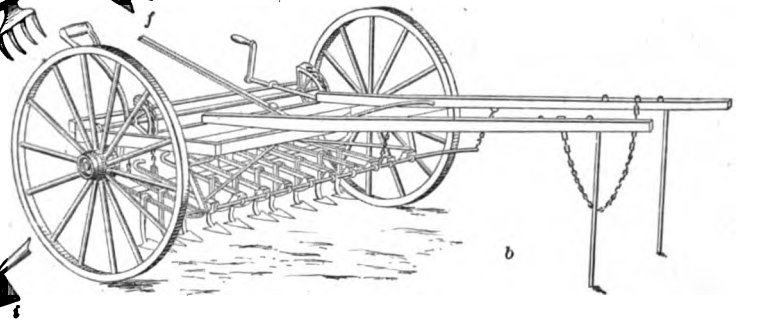
Fig. 2520.

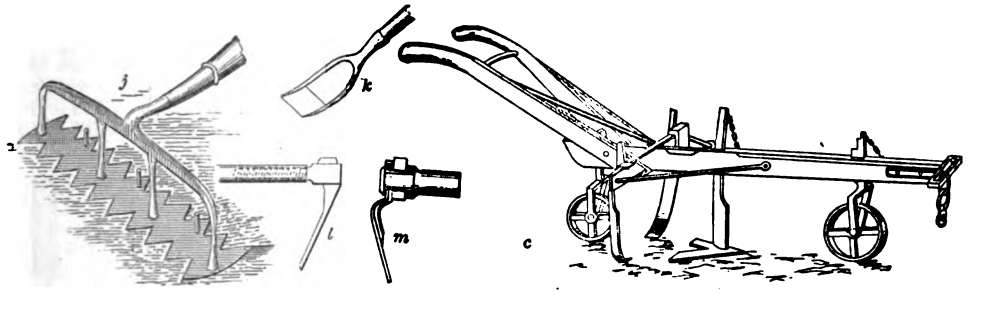


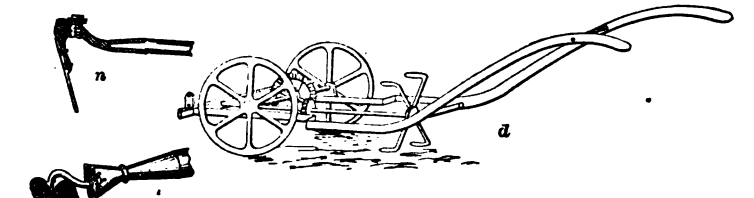
Hoes.

Fig. 2521









Hoeing-Machines.

Digitized by Google

needs no wheel. For turning at the end of a row of corn or potatoes it is too long. A man would need 12 feet of ground to come out on to turn, and it is not necessary to withdraw so large a marginal strip of the field for such a purpose. See CULTIVATOR.

Bucknalls's horse-hoe *b* (English) has a gang of 10 shares in a frame, adjustable by a lever as to hight, and also as to angular presentation of the shares to the ground. It is intended for hoeing wheat.

An implement used for chopping gaps in drilled rows of plants was described by Skirving of Fifeshire, Scotland, in 1778, and constructed by Huckvale some 25 years since (*d*, Fig. 2521). It was designed for turnip culture, and is also used in cotton culture. In each case the seed is sown somewhat abundantly in drills, and requires to be thinned after having attained such size as to bear culture. The practice with cotton has been to cut gaps in the rows with a hoe, leaving the plants in square bunches, which are afterward thinned out to a few plants, and eventually, when the contingencies of insect enemies are overpast, leaving the most likely plant in full possession of the hill.

This *horse-hoe* is designed for chopping gaps in the rows, and has a set of revolving hoes on a shaft parallel with the line of draft, and driven by bevel gearing from the main axle of the machine. As the machine advances, the hoes chop transversely across the row of plants, making intervals therein equal to the lengths of the blades. See COTTON-CHOPPER.

Hog. 1. (*Paper-making.*) A revolving stirrer in a chest of paper pulp which agitates the pulp so as to keep it of uniform consistence as it flows to the paper-making machine. See PAPER-MAKING MACHINE.

2. (*Nautical.*) A scrub-broom for scraping a ship's bottom, under water.

Hog-chain. (*Shipbuilding.*) A chain in the nature of a tension-rod passing from stem to stern of a vessel, and over posts nearer amidships; designed to prevent the vessel from drooping at the ends.

Hog-el'e-va'tor. A hoisting device used in large slaughter-houses for raising hogs which have been killed, scalded, and scraped, to the position for gutting and cleaning.

Hog-frame. (*Shipurrighting.*) A fore-and-aft frame, forming a truss in the main frame of the vessel to prevent vertical flexure.

The term "hog-frame" has been adopted into carpentry and engineering in some forms of trusses for roofs and bridges.

Hog'ger-pipe. (*Mining.*) The upper terminal pipe with delivery hose of the mining-pump.

Hog'ger-pump. (*Mining.*) The top pump in the sinking-pit of a mine. The lower is the *sump-pump.*

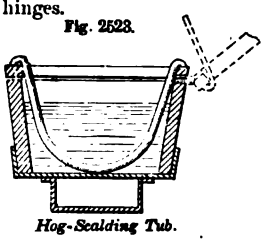
Hog'ging. (*Nautical.*) Said of a ship's shape when the head and heel of her keel are drooped; the middle portion curving upwardly. *Sagging* is the opposite curvature.

In other structures than nautical the term has the same relation, as the drooping of the ends of a truss, or the ends of a pivot bridge or table.

Hog-hook. One used in handling hogs in scalding.

Hog-scald'ing Tub. (*Domestic.*) A means for scalding hogs, consisting of a large boiler and furnace, or a tub (Fig. 2522) to hold heated stones which are thrown in to raise the temperature of the water to scalding heat. In the example (Fig. 2523) the hog lies in a cradle within the tub, whose contents are heated by the furnace below. The hog is removed and tipped out on to a bench, by vibrating the cradle on its hinges.

Fig. 2523.



Hog-Scalding Tub.

Fig. 2524.

Nose-Ring.

Hog's-nose Trim'mer. A pair of cutting forceps or nippers, to remove the protuberant cartilage from a hog's snout to discourage him from rooting.

Hog-ring. A ring, or wire bent into other form, clasping the snout cartilage of a hog. In the example, the pivoted extensions of the ring penetrate the hog's snout, and, turning back, clinch round the ring.

Hoist. 1. The term applied to the elevating machinery of a factory, mine, or hotel.

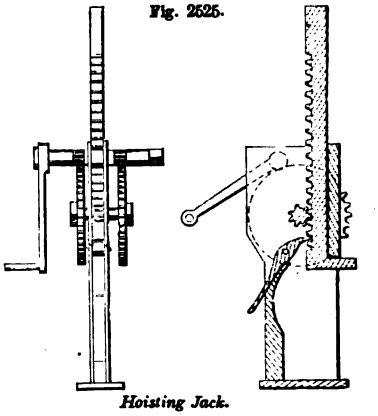
2. The perpendicular hight of a flag; the length from the spar outwards is the *fly.*

Hoist-bridge. A form of drawbridge, in which the leaf or platform is raised. See BASCULE.

Hoist'ing-en-gine. A steam-engine for hoisting at a mine, or in a warehouse, factory, etc.

Hoist'ing-jack. A contrivance by which hand-power is applied to lifting an object by working a screw or lever. A list of the different kinds is given under JACK. Several varieties are described under CARRIAGE-JACK, WAGON-JACK, JACK-SCREW, etc.

Fig. 2525.



Hoisting Jack.

One form here shown operates by crank, pinions, cog-wheel, and rack.

The other is a suspensory jack, depending from an eye-bolt in a ceiling-joist and used to lift an object a short distance, so as to get it on to a store truck.

Fig. 2522.

Hog-Hook.

Digitized by Google

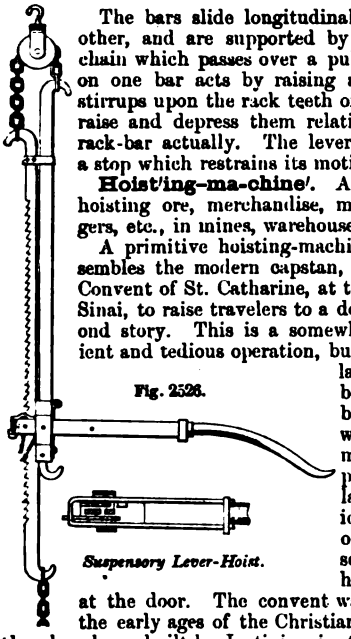


Fig. 2526.

Suspensory Lever-Hoist.

The bars slide longitudinally upon each other, and are supported by a connecting chain which passes over a pulley. A lever on one bar acts by raising and returning stirrups upon the rack teeth of the other to raise and depress them relatively, and the rack-bar actually. The lever is locked by a stop which restrains its motions.

Hoist'ing-ma-chine'. A machine for hoisting ore, merchandise, miners, passengers, etc., in mines, warehouses, hotels, etc.

A primitive hoisting-machine, which resembles the modern capstan, is used in the Convent of St. Catharine, at the foot of Mt. Sinai, to raise travelers to a door in the second story. This is a somewhat inconvenient and tedious operation, but is used in a land where robbers go on horseback. It is also worthy of remark, that the people of the land have no idea of the value of time, and so set six men to help another in at the door. The convent was founded in the early ages of the Christian Church, and the chapel was built by Justinian in the sixth century. It is a vast, straggling building, surrounded by a high wall, and is believed by its residents to occupy the place whereon the Lord appeared to Moses in a burning bush.

Fig 2527.

Hoisting-Machine, St. Catharine's Convent, Mt. Sinai. (*From Harper.*)

The obelisks in ancient Egypt may have been raised by gradually lifting the apex and scotching up by introducing earth beneath them.

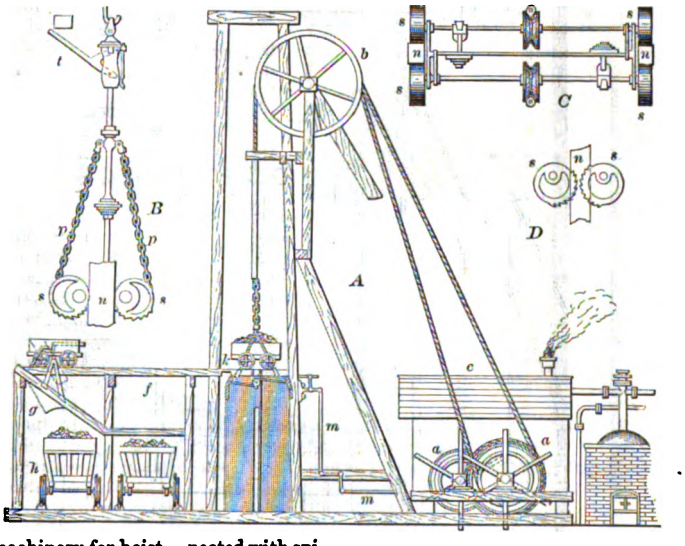
The Stonehenge blocks were probably raised in the same way.

The blocks were moved from the quarries on rollers by animal or man power. They were perhaps raised, at the pyramids, for instance, by a rocking motion on midway blocks, a rather thicker block from time to time, at each rock. Or they may have been raised on an incline of earth, afterwards removed.

When Chersiphon built the Temple of Ephesus, in the time of Amasis of Egypt, he raised the architrave by surrounding the columns with bags of earth, which served as an inclined plane.

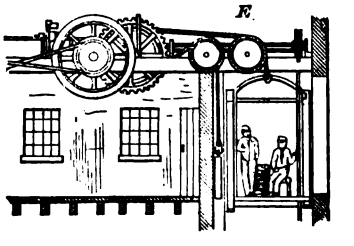
Fig. 2528 shows forms of hoisting-machines for coal-mines and factories.

Fig. 2528.



A is a general elevation of the machinery for hoisting, screening, and loading coals, which will be readily understood by merely citing the parts. *a a* are the rope-drums, driven by the engines in the house *c*; *b* the pit-head pulley; *k* the cage which lifts the folding boards of the hatchway, and then, allowing them to drop, rests upon them. The car is then run out upon the track *f*, its load dumped upon the screen *g*, and received in the wagons *h*. On the return of the empty car on to the cage, the hatches are lifted by the engine-man by means of the rods *m m*.

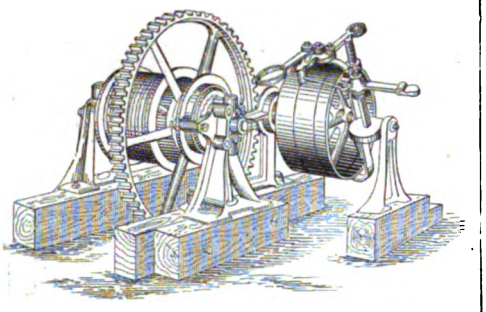
B, *C*, *D*, show the safety apparatus, by which, if the hoisting-rope break, the cage is prevented from falling by the biting of the toothed eccentrics *s* upon the wooden conductor *n*. The eccentrics are connected with spiral springs, which tend to rotate them, and bring the toothed part against the conductor *n*; but so long as the rope remains intact, the working faces of the eccentrics are



Mine and Factory Hoists.

Digitized by Google

Fig. 2529.



Sellers's Hoisting-Machine.

firmly held by the chains *p* from contact with the conductor. *t* is a trigger which releases the cage in case of overwinding.

E is a factory-hoist like the modern elevator so much used in hotels. It is known in the North of England as a *teagle* (? *tackle*).

Sellers's hoisting-machine for warehouses or hotels is shown at Fig. 2529. It exhibits the wire-rope drum together with the up-and-down pulleys, and the middle loose pulley.

Fig. 2530 exhibits the hoisting-machine with the steam-engine by which it is driven. This is a double-cylinder, and reverses by a single movement of the valve-lever at the front. The platform moves at a speed of from 10 to 150 feet per minute, and has safety-ratchets which instantly lock it to the standards if the rope break. The drum on which the wire rope is wound has a spiral groove in which successive coils of the rope are kept separate. The car stops automatically at certain limits, or by hand at intermediate points. See ROPE-ELEVATOR.

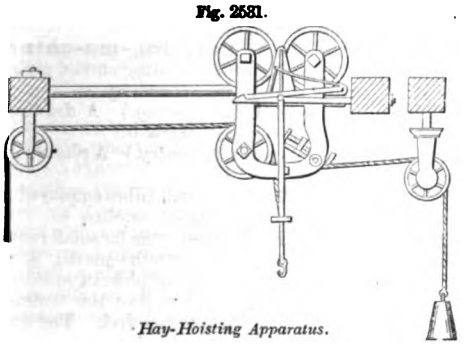
Among the modern facilities for taking care of farm produce, the horse hay-fork suspended by tackle from an elevated beam in the barn deserves a special mention. For the varieties of the fork, see FORK. This device is usually suspended by tackle from the beam by means of a clutch or tongs. (See CLUTCH.) The clutch, however, is not the only means of suspending the tackle and fork; in stacking hay a derrick is used, and in some barns a still more complicated device. When the load has reached its elevation, a pawl is raised which allows the carriage to traverse on the track and transport the load horizontally and return when the load is discharged. The brake moderates the rate of the hoisting-rope in running over the pulleys.

Fig. 2531.



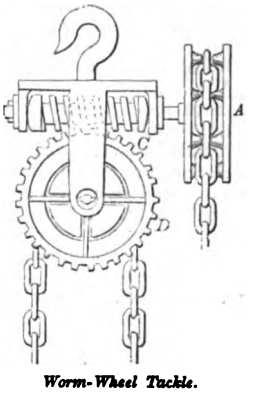
Hay-Hoisting Apparatus.

In another form of hoisting-machine, a platform, provided with rollers at its bottom, rests upon a large worm-wheel which meshes equally into two vertical worm-racks or segmental screws. Motion is imparted to the worm-wheel by a small gear-wheel meshing with a toothed rack on the lower surface of the worm-wheel.

Under this head may also be mentioned a device for lifting bricks, mortar, etc., to the top of buildings in course of erection. In this, buckets for the elevation of building material are fixed upon an endless chain. The chain is worked by a windlass at its upper end.

Hoist'ing-tack'le. A rope or chain and pulley used for hoisting. The simplest form of tackle is the *whip*, then follow the *whip-on-whip* and other forms of tackle cited in the list above. The form shown in Fig. 2533 is a differential tackle, and consists of two shafts, on each of which is a sprocket and a gear-wheel, the two latter meshing with each other. The proportion between the diameters of the gear and sprocket wheel on one shaft differs from the proportion between the diameters of the gear and sprocket wheels on the other shaft, in order that by overhauling the endless chain which is connected with the teeth of the two sprocket-pulleys, the block bearing the weight to be raised and connected by the chain with the sprockets may be raised or lowered as desired. The lower sprocket-wheel is applied so that it may be thrown out of connection with the upper one and locked so as to prevent retroaction.

Fig. 2532.



Worm-Wheel Tackle.

Fig. 2533.

Differential Hoisting-Tackle.

Fig. 2532 has a large wheel *A* on which is a worm *C* gearing into the chain-wheel *D*. Such a tackle will hold its load at any point at which the power ceases to be applied, and will not allow it to come down "on the run." The threads of a screw act as a stop or check to the windlass wheel.

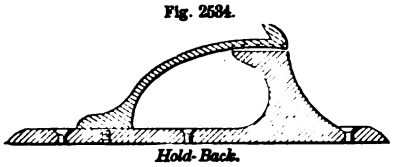
Hold. (*Shipwrighting.*) The interior part of a

Digitized by Google

ship, in which the cargo of a merchant vessel or the provisions and stores of a man-of-war are stored. The portions are distinguished as the *fore*, *main*, and *after* holds.

Hold-back Hook. (*Vehicle.*) A projection on a carriage-shaft to which the breeching-strap of

Fig. 2534.



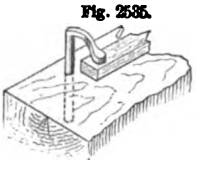
Hold-Back.

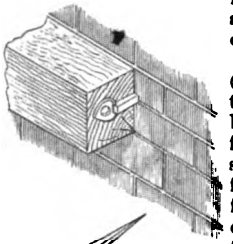
a horse is connected, to enable the animal to hold back the vehicle.

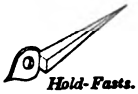
Hold-beam. (*Shipbuilding.*) One of those which support the lower deck in a merchantman; the *orlop* deck in a man-of-war.

Hold-fast. A means by which something is clamped to another.

Fig. 2535.







Hold-Fasts.

The bench *hold-fast* is an arched bar, whose shank passes through a mortise in the bench, the *dog* pressing upon the work to be held. See BENCH-CLAMP.

A wall *hold-fast* is a spike, which is driven into the wall, and has a flat head through which a nail is driven into the object to be attached.

Hold'ing-down Bolt. (*Steam-engine.*) One of twelve or more strong bolts, which are passed from the outside of a steam-vessel through the floor-timbers, sleepers, foundation-plate of the engine, and the bosses on the cylinders, condensers, and side-frames, and are secured by strong nuts. The bolts are of copper or tinned iron, to resist the action of sea-water.

Hold'ing-up Ham'mer. A hammer held by the assistant against the head of the rivet while it is being riveted. See RIVETING.

Hole. A depression made to hold a blast.

Sinking, *boring*, *pumping*, *drilling*, are terms made use of.

Loading or *charging* the hole is the putting in of the powder.

Tamping is the packing of material upon the powder.

Hole-board. (*Weaving.*) See COMPASS-BOARD.

Hol'ing. 1. (*Mining.*) The under-cutting of coal by means of a pick wielded by a man lying upon his side. The making of vertical cuts at the sides is called *shearing*, and when these are made the stratum of coal is broken down by wedges driven in above.

2. (*Roofing.*) Piercing slates for holding nails.

Hol'ing-axe. A narrow axe for cutting mortises in fence-posts, for a *post-and-rail* fence.

Hol'land. (*Fabric.*) Linen or linen and cotton goods, white or self-colored, and with a glazed surface. Used for linings. As originally imported from Holland (whence its name), it was closely woven linen cloth.

Hol'low. A depression or unoccupied space, as—

a. The empty portion of a bastion.

b. The part of a cantle under the crupper-loop.

c. The gullet of a saddle under the pommel.

d. The depression in an anvil-face or fullering-tool used in forging round work.

e. A cavetto or recess bead in molding.

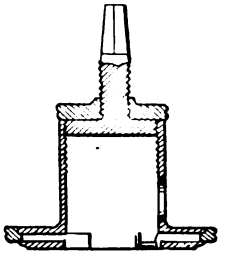
f. The seat of the shot in a counterbored gun. A *dent*.

Hol'low-adze. (*Coopering.*) A howel; a tool having a curved blade to chamfer the chine on the inside of a cask end.

Hol'low-au'ger. One for making round tenons in chair-work, on spokes, etc.

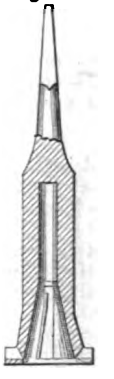
The end of the spoke or other piece of wood on which a round tenon is to be cut, is inserted into the tubular portion, whose throat has several radial rests and a radial cutter. The tool is revolved, and the blank is fed forward on the rests. The length of the tenon is gaged by the adjustable stop at the rear end of the tube.

Fig. 2536.



Hollow-Auger.

Fig. 2537.



Tenon-Auger.

Fig. 2537 is a form in which the auger cuts a tapering tenon and a shoulder upon the spoke simultaneously.

Hol'low-au'ger Bit. A wood-boring tool adapted to be used in a brace. It is of a hollow cylindrical form, and has cutters presented inwardly which make a cylindrical tenon on the end of the stuff. See HOLLOW-AUGER.

Hol'low-drift. 1. A tubular tool for driving a hole. See DRIFT.

2. A tool used in filling signal-rockets.

Hol'low-edge File. A file with a concave edge for dressing teeth of small gear wheels and pinions.

Hol'low-ing and Back'ing-ma-chine'. (*Coopering.*) A machine for rounding staves, giving the outer convexity and inner concavity.

Hol'low-ing-knife. (*Coopering.*) A drawing-knife for working on concave surfaces.

Hol'low-ing-plane. (*Carpentry.*) A plane with a round convex sole.

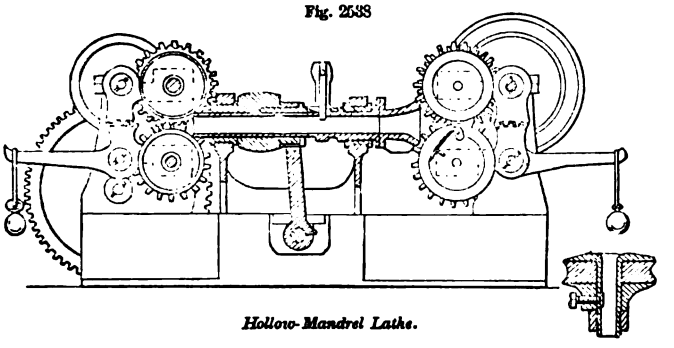
Hol'low-joint Wire. Small tubes employed in making joints, as in the casing of watches.

Hol'low-man'drel Lathe. One for small round stuff, such as broom-handles, scythe-snaths, stuff for clothes-pins, chair-rounds, round pickets, rails, etc. The stuff is fed by grooved rollers into the trumpet mouth of the revolving hollow mandrel. The tool

Digitized by Google

projecting from the internal periphery of the mandrel turns the blank into shape. The spring forms a stop for the strip, and its position indicates the time for its insertion berween the feed-rollers. The

Fig. 2538



Hollow-Mandrel Lathe.

rollers which draw out the turned stick have circumferential depressions, which contain grooved annuli of rubber, which press with an adjustable force on the handle.

Hol'low-new'el. The well-hole or opening in the center of winding stairs. *Open-newel*, in contradistinction to *solid-newel* or *corkscrew* staircase.

Hol'low-plane. A molding-plane with a convex sole. A *round-sole* plane.

Hol'low-punch. (*Saddlery and Shoemaking.*) The hollow punch is employed to make holes for rivets in leather; holes for eyelets in paper, leather, or fabric; holes for laces in shoes and stays, and on other occasions where a smooth, round hole is to be cut out of a yielding material. It is also known as an *eyeleting*-punch from its use as a means for punching holes for eyelets.

In a modified form, as the punch-pliers, it is used for punching cardboard tickets, tags, and papers for filing. A *ticket-punch.*

A *wad-cutter* is also a hollow punch.

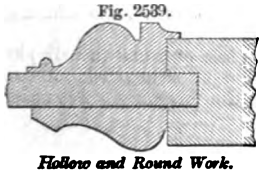
Hol'low-quoin. (*Hydraulic Engineering.*) One having a vertical recess for the hanging-post of a lock-gate to abut against.

Hol'low-rail. A tubular railroad rail, steam heated to prevent the accretion of snow and ice. Grime's English patent, 1831.

In Woodhouse's English patent, 1803, the rail forms a water-pipe.

Hol'lows and Rounds. (*Joinery.*) Concave and convex planes, respectively for working moldings. The illustration shows the use of *hollows and rounds*, in the molding of a panel door. They are made in pairs, and as many as eighteen pairs to a set.

Fig. 2539.



Hollow and Round Work.

Hol'low-ware. Cast-iron culinary vessels, such as pots, kettles, skillets, etc.

Ho-lom'e-ter. An instrument for taking measurements. See METER.

Hol'o-pho'tal Light. (*Optics.*) A name applied to such forms of lighting-apparatus for lighthouses as utilize the whole of the available light, by subjecting it all to the corrective action of the instrument; as, for instance, Thomas Stevenson's CATADIOPTRIC LIGHT (which see).

Hol-o-ster'ic Ba-rom'e-ter. One made of solid materials, so as to show variations of atmospheric pressure without the intervention of liquids.

The *aneroid* of Vidi, and the bent tube of Bourdon, are examples of *holosteric* barometers, but the word is sometimes used specifically to denote the former. The barometer constructed on the principle of the balance is described in Leupold. See BAROMETER.

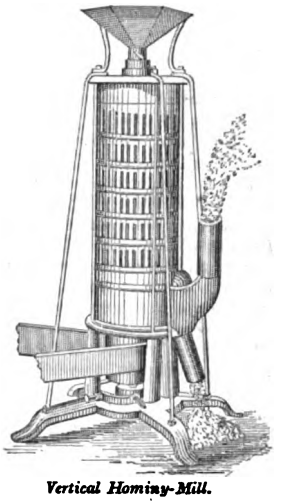
Hol'ster. 1. A leather case by the saddle-bow to hold a pistol.

2. A pistol-case carried on the person.

Ho'ly-stone. A large stone used with sand for scouring a ship's decks.

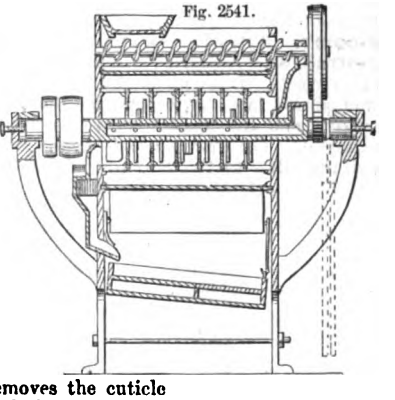
Hom'i-ny-mill. A machine in which shelled corn is subjected to a grating or beating action which removes the cuticle and the germ, and, by persistent and sufficiently energetic action may break the grain as small as may be wanted. The sizes are graded by sifting.

Fig. 2540.

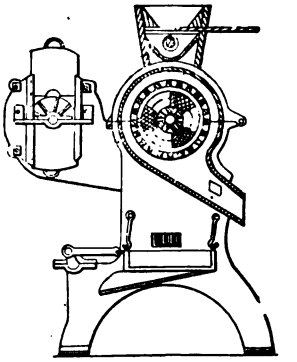


Vertical Hominy-Mill.

Fig. 2541.



In Fig. 2540 the corn is fed in above, and is subjected to the action of a series of beaters on the rotating vertical shaft. A fan in the case below blows out the dust, bran, and powdered germ.



Horizontal Hominy-Mill.

Digitized by Google

In Fig. 2541 the mill consists of a double case, the inner shell of which is provided with semi-annular plates or partitions. Within the case is a revolving hollow scouring and blowing shaft, having an air-gathering cup or scoop upon one of its ends, and at the opposite end is a discharge-spout and a blast-passage. Roughened scouring and smooth conveying blades are set spirally around the hollow blowing-shaft.

Hone. A flat slab, usually of some description of slaty stone, used for giving a keen edge to a cutting-tool after sharpening on the grindstone. Various kinds, differing greatly in texture and hardness, are employed. Norway ragstone, water-of-Ayr, bluestone, German-hone, and many other varieties, have a more or less extended reputation for their adaptation to special requirements, being used either dry or moistened with water or with oil. The *Turkey oil-stone*, which comes from Asia Minor, is generally known, and is employed for imparting an edge to chisels, plane-bits, and all the finer varieties of cutting-tools. It is usually cemented in a slab of wood and provided with a wooden cover.

The finest variety of stone suitable for hones is found in Arkansas, and is also known as Washita.

The metallic hone is a small round bar of steel, with fine longitudinal striations. For use it is moistened with oil and sprinkled with rottenstone or other fine abradant.

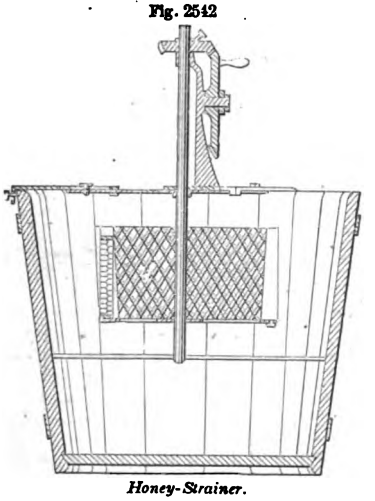
Fayrer's swing hone is a strip of brass pivoted at each end, so as to adjust itself to the edge of the razor. An abrading powder mixed with oil is applied upon one side, on which the razor is roughly sharpened, when the brass slip is turned and a keen edge imparted by the other side, moistened with a finer composition and oil.

Artificial stones and emery-charged leather are also used as hones. See GRINDING AND POLISHING.

Hon'ey-comb. A flaw in a casting.

Hon'ey-strain'er. A device for separating the honey from the comb. In a common form the comb is cut up and placed in a tub or tray to allow the honey to drain from the broken cells. In other cases it is pressed. The example is an application of the centrifugal filter to this purpose. After the

Fig. 2542



Honey-Strainer.

cap has been cut off the comb, it is placed in a wire-gauze basket which is rapidly rotated. The honey is thrown out by centrifugal force. The drained combs are returned to the hives to be again filled with honey.

Hon'i-ton-lace. (*Fabric.*) A variety of lace made by placing a perforated pattern upon a pillow, and then so twisting and interweaving the thread by means of bobbins, pins, and spindles, as to produce the required pattern.

Hood. 1. (*Mechanical.*) A dome-shaped projection or canopy over a discharging or receiving orifice in a structure, as of a fireplace, chimney, or ventilator.

A *cowl* over a chimney, ashore or aboard.

2. (*Wear.*) A soft covering which shrouds the head. Some are attached to a cloak. "With any that wears a *hood*." "A *cowled* monk."

3. (*Vehicles.*) A carriage-top which may be elevated or depressed.

4. (*Hydraulic Engineering.*) The capping of the piles of a starling.

5. The top of a pump.

6. The *companion* of a hatchway.

7. (*Nautical.*) *a.* A covering for a companion-hatch, scuttle, chain-pump, or skylight. A *cowl* for the galley chimney.

b. One of the foremost or aftermost planks of a strake. The *hood-ends* fit into the rabbets of the stem and stern posts.

8. (*Saddlery.*) The leathern shield in front of a wooden stirrup, which serves to protect the foot of the rider.

9. (*Sporting.*) The blinding cap on the head of a hawk to make him sit quietly on his perch. Said to have been invented by the Arabians.

Falconry was an ancient custom in Tartary; Ctesias, contemporary of Alexander the Great, mentions that hares and foxes were hunted in India by falcons. Aristotle speaks of the practice in Thrace. It was common in Italy in the time of Martial.

It attained its climax in Europe in the twelfth century.

Hood'ing-end. (*Shipbuilding.*) The end of a *hood* or endmost plank of a complete strake. The *hooding-ends* fit into rabbets of the stem and stern posts.

Hood-mold'ing. (*Architecture.*) A crown-molding. A *head*-molding.

Hood-quar'ter. (*Vehicles.*) One of the side pieces of the back portion of a hood.

Hoof-pad. (*Menage.*) A device attached to the hoof of a horse to keep the foot, or the shoe of the foot to which it is attached, from cutting the fellow foot or the fetlock. A device to prevent *interfering*.

Hoof-par'ing Knife. (*Farriery.*) A knife with a recurved blade, used for paring hoofs, to fit horse-shoes thereon; the sharply curved portion enables the knife to act as a *scorper* in the fissures between the *frog* and *sole*. See *g*, Fig. 2545.

Hoof-spread'er. (*Farriery.*) A device for expanding mechanically the hoof of a horse suffering from contraction of the foot.

Hook. 1. A curved piece of metal (usually) by which an object is caught or suspended. A tool having a shape similar to the foregoing. See under the following list:—

Axle-hook.	Cat-hook.
Bench-hook.	Chain-hook.
Bid-hook.	Check-hook.
Bill-hook.	Chimney-hook.
Bloom-hook.	Clasp-hook.
Boat-hook.	Clothes-line hook.

name of hardware, and whose names indicate their purpose: —

Awning-hook.
Bird-cage hook.
Cabin-door hook.
Clothes-hook (*f a b c*).
Cotton-hook.
Dressing-glass hook.
Harness-hook (*j*).
Head-board hook (*i*).
Hook and eye (*d*).
Horse-hitching hook.
Lamp-hook.
School-house hook.
Screw-hook (*h*).
Wardrobe-hook (*a b c*).

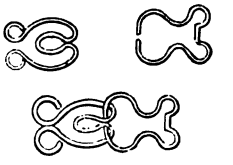
2. (*Shipbuilding.*) A knee or strengthening frame conforming to the inner shape of the vessel and supporting the bow or forward ends of the decks. See STEM.

3. (*Knitting-machine.*) The barbed extremity of the needle, which retains the yarn. The *beard*.

Hook and Butt. A mode of scarfing timber so that the parts resist tensile strain to part them. A *hook-scarf*. See SCARF.

Hook and Eye. An ordinary fastening of ladies' dresses. Made of flattened wire and bent to form, as in the example.

Fig. 2544.



Hook and Eye.

Hook-block. A pulley-block strapped with a hook, in contradistinction to one with an *eye* or a *tail*. See cut of BURTON.

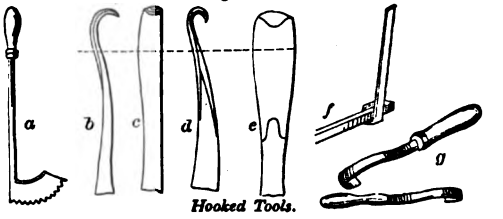
Hook-bolt. A bolt with a hook-head. Used on board ship to fasten lower-deck ports.

Hook-butt. (*Carpentry.*) A mode of scarfing timber. See SCARF.

Hooked-bolt. One with a lip used to fasten boards on to a ship's frame or a wharf.

Hooked-tool. 1. A marble-worker's chisel (*a*),

Fig. 2545



Hooked Tools.

the end bent to a right angle, and used in positions where the square chisel cannot be readily employed.

2. Wood-turning tools of the nature of scorpers (*b c d e*).

3. A bent iron rod (*f*) forming three sides of a square, one end being prolonged for a handle. Used in *taking the twist out* of a bar while forging.

4. A hoof-paring knife (*g*).

Hook'er. (*Nautical.*) A one-masted merchant vessel of the English and Dutch waters. A *howker*.

Hooke's Gear'ing. A kind of gearing in which the teeth are somewhat obliquely across the face of the wheel, so that the contact of each tooth commences at its foremost end and terminates at the aftermost end; the *pitch* of the spiral is such that the contact of one pair of teeth does not terminate until that of the next pair has commenced.

Hooke's stepped gearing is of a somewhat similar design.

Hooke's Joint. A universal joint. A GIMBAL-JOINT (which see).

Hook'ing-frame. A frame with hooks upon which cloth is measured and suspended, being folded back and forth until the required quantity is reached, when it is cut off and removed to be packed.

Hook-mo'tion. (*Steam-engine.*) A valve-gear having hooks for actuating and reversing.

Hook-rope. (*Nautical.*) One six or eight fathoms long, with a hook and thimble spliced at one end and whipped at the other. It is used to drag chain and for similar purposes.

Hook-scarf. (*Carpentry.*) A mode of fastening timbers together endways, so that they lock to each other. See SCARF.

Digitized by Google

Fig. 2546.

Hooking-Frame.

Hook-tool. (*Lathe.*) *a.* A form of hand-tool used in metal turning, which is of a hook shape, and is supported on a rest below and beyond which it extends. A HANGING-TOOL (which see).

b. A wood-turning tool having a bent portion used for bottoming boxes, or lids, or other hollow work. See Fig. 2545.

Hook-wrench. A form of spanner which has a bent end adapted to grasp a nut or coupling piece and turn it. See Fig. 2545.

Hoop. 1. (*Coopering.*) A strip of metal or wood united at the ends and driven around a cask to hold the staves together.

Hoops for casks are known as: —

Bulge-hoop; the hoop nearest the swell of a cask.

Chine or *chime* hoop; or *head*-hoop; the hoop nearer to the end or *chine*.

Flat-hoop; a thin hoop; flat on both sides.

Half-round hoop; a hoop whose outside is the undressed exterior of the pole.

Quarter-hoop; an intermediate hoop between the bulge and chine.

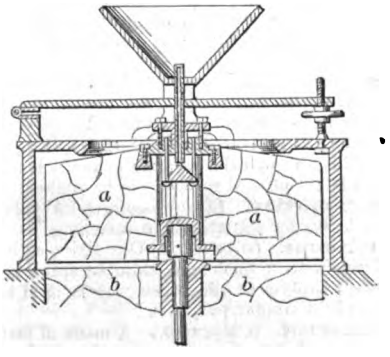
Truss-hoop; a stout hoop of wood, used before or preliminary to the final hooping.

2. (*Nautical.*) *a.* One of the rings to which the *weather-leach* of a *fore-and-aft* sail is bent, and by which it slides on the *mast* or *stay* as the sail is hoisted or lowered. A *hank*.

b. A band on a wooden anchor stock.

3. (*Milling.*) *a.* The enclosing case of a run of stones. It stands on the husk. *a* is the runner, *b* the bed-stone.

Fig. 2547



Grinding-Mill.

b. A metallic band around a mill-stone.

4. A strap around an eccentric.

5. (*Apparel.*) *a.* A thin strip (usually of steel and covered with braid), used in expanding the skirts of ladies' dresses.

b. A frame made of pliable, steel, braid-covered hoops, united by vertical tapes and adapted to expand the skirt of a lady's dress. Frames of similar shape but differently constructed were in use in the time of Pope and of Queen Bess.

Hoop-bend'ing Ma-chine'. (*Coopering.*) A machine for curving hoops; generally consisting of a set of three rollers between which the hoop is passed, the upper roller acting against and between the two lower ones, and having its lower surface depressed below the upper line of the two lower ones.

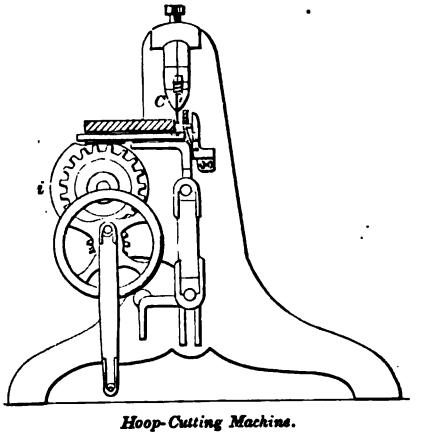
Hoop-coil'ing Ma-chine'. (*Coopering.*) A machine by which split, sawn, or cut hoop-stuff for barrels is wound upon a drum so as to be secured in a coiled condition for shipment and use.

Hoop-cramp. (*Coopering.*) A ring-clutch for holding the ends of a hoop which are lapped over each other.

Hoop-crimp'ing Ma-chine'. (*Coopering.*) One for giving the bend to hoop-stuff to render the hoops tractable in fitting to barrels and casks.

Hoop-cut'ting Ma-chine'. (*Coopering.*) One for cutting from the log or from the edge of a board a slat for a hoop. When made from the log, the latter is rotated between each cut, and the knife makes an incision a depth equal to the width of the hoop, which is removed by another cutter. In cutting from a board, a reciprocating knife *C* cuts hoops from the edge of a plank resting on a table which is alternately raised and lowered by a cam *i* to impart an edgewise taper or bevel to the hoops.

Fig. 2548.



Hoop-Cutting Machine.

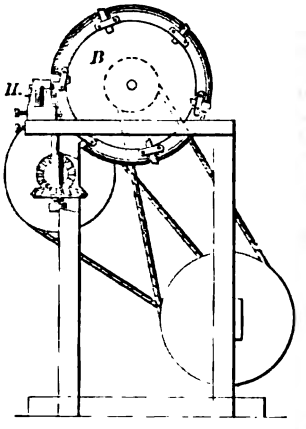
Hoop-dress'ing Ma-chine'. (*Coopering.*) A machine for dressing rived hoops to an even thickness. In the example, the hoops are dressed by means of a revolving cutter-wheel, in connection with a guide-block and pressure and feed roller. The lower part of the figure shows the operation more in detail, the hoop passing between the rotary cutter *B* and the head-block *H*. *L* is the feed-roller.

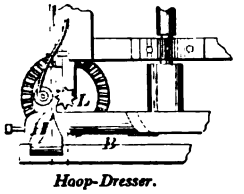
Hoop-driv'er. (*Coopering.*) *a.* A hand-tool which is rested on the edge of the hoop and beaten by a hammer or mallet to force the hoop on to the cask.

b. A machine by which the hoops are forced on simultaneously.

Digitized by Google

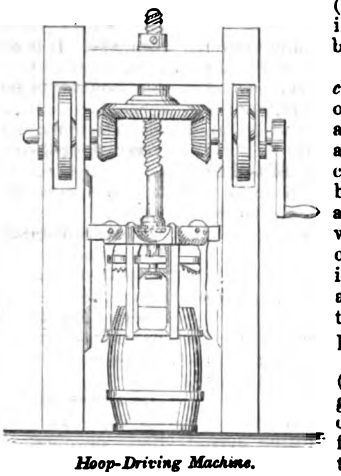
Fig. 2549.





Hoop-Dresser.

Fig. 2550.



Hoop-Driving Machine.

Attached to a screw-shaft revolved by gearing is a head to which are pivoted pendant drivers, which are adjusted to the side of the cask by a cam-disk with projections on the periphery that force the drivers outward as it is turned, and by revolving the screw-shaft, the head is depressed and drives the hoops upon the cask.

Hoop'ing. (*Founding.*) The iron-work around a molding-box.

Hoop-iron. Flat, thin bar-iron.

Hoop-lock. 1. (*Coopering.*) *a.* A mode of connecting the ends of the split pole or slat which forms a hoop.

b. One of the interlocking notches near the ends of a barrel-hoop.

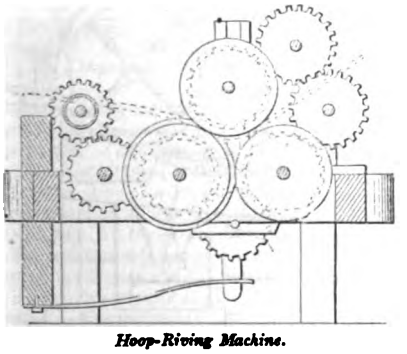
Machines are made for cutting hoop-locks, having descending cutters shaped to the curved form of the notch required.

2. A fastening for the ends of hoops; used in baling hay or cotton. See BALE-TIE.

Hoop-plan'ing Ma-chine'. (*Coopering.*) A machine for thinning down and dressing the surface or surfaces of hoop-pole stuff, or of stuff sawed or cut for hoops. See HOOP-DRESSING MACHINE.

Hoop-punch'ing Ma-chine'. (*Coopering.*) A machine for punching rivet-holes in iron hoops for casks.

Fig. 2551



Hoop-Riving Machine.

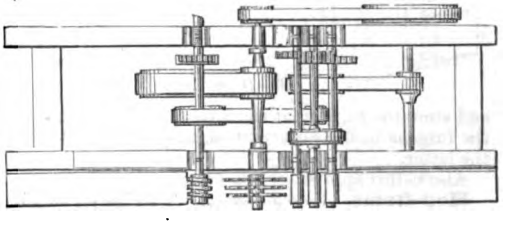
Hoop-rack'ing Ma-chine'. (*Coopering.*) One for forcibly bending rived hoops to make them tractable in placing them around casks.

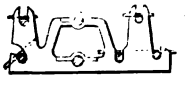
Hoop-riv'ing Ma-chine'. (*Coopering.*) A machine in which the bar of wood to be rived is sawed out of a proper width for the hoop required, and the end checked by a gang of circular saws. The end is then placed between the guiding friction wheels and advanced to the groove of the wheel, where it is seized by the bite of the upper pressure disk, and passing along is deflected upwards by another wheel emerging from between the latter wheel and the upper disk in a riven condition.

Hoop-saw'ing Ma-chine'. (*Coopering.*) *a.* A machine in which gaged stuff is fed to a gang of circular saws and reduced to dimensions for making hoops. In the example, the saw-shaft has journal bearing either above or below the guide-rollers. The guide-rollers are kept in their journals by pins traversing the upwardly projecting sides of the said journals.

b. A machine which removes, by successive actions, a thin strip for the edge of a board.

Fig. 2552.





Hoop-Sawing Machine.

c. A machine which saws hoops from a log, which is rotated between each cut, the thickness of a hoop plus the kerf; the saw cutting down into the log the width of a hoop, and a second saw or a cutter removing the hoop so cut.

Hoop-shav'ing Ma-chine'. (*Coopering.*) One for reducing the thickness of hoop stuff, and dressing the edge which lies against the cask. See HOOP-DRESSING MACHINE.

Fig. 2553.

Hoop-Skirt

Digitized by Google

Hoop-skirt. The fardingale of the time of Queen Elizabeth. See also the "Tatler," January 5, 1710.

The modern hoop-skirt is formed of braid-covered flat steel-wire hoops, united by tapes and shaped upon a former. Various ingenious devices are adopted for making, tempering, covering, marking, and sizing the wire, for clasping the *spangles* which unite the tapes and wires at their intersections.

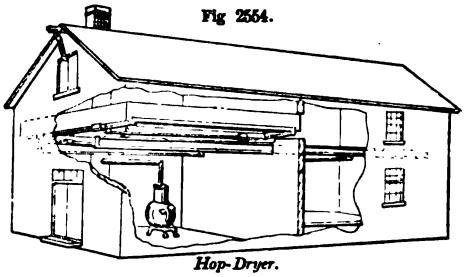
Hoop Splay'ing and Bend'ing Ma-chine'. (*Coopering.*) A machine for spreading hoop-iron on one side so as to enable it to set snugly on the bilge, and at the same time bending the hoop to the curve of the cask.

Hoop-split'ting Ma-chine'. (*Coopering.*) A machine to rive hoops from stuff properly prepared. See HOOP-RIVING MACHINE.

Hop-back. (*Brewing.*) The vessel beneath the copper which receives the infusion of malt and hops, and has a perforated bottom which strains off the hops from the unfermented beer.

Hop-dry'er. A chamber in which hops are artificially dried. In the example, a tilting drying-frame runs on a track extending through the drying

Fig 2554.



Hop-Dryer.

and store rooms, so that the hops, after drying above the furnace in the former room, may be deposited in the latter.

Also called an *oast*, or *hop-kiln*.

Hop-frame. (*Agriculture.*) A trellis on which hops are supported while growing. Hops are usually grown on poles, which are pulled out of the ground and laid across trestles for the convenience of the hop-pickers. Hop-frames are some of them made to recline to bring them within reach of the pickers.

Hop'per. 1. (*Machinery.*) A chute for feeding any material to a machine. It is generally of an inverted frustal shape, as in brick-machines for feeding clay to the pug-mill; in winnowing-machines, for feeding the grain and chaff to the upper riddle; in grinding-mills, for feeding grain to the stones. Its name is derived from the latter, as it used to be shaken by a *damsel* (projection) on the spindle, in order to keep the grain fed down into the throat. It now feeds the grain into a shaking *shoe*, which is agitated by the *damsel*. See GRINDING-MILL.

The term is also applied to the reservoir which contains the grain in seeding-machines, planters, drills, etc.

The term is also applied to a feeder, such as the fuel reservoir of a stove.

The holder of blanks in a machine, as the screw-blanks in a screw-cutting machine. The planchets in a coining-machine, eyelets or spangles in machines using those articles, and many others too numerous to mention.

2. The basin of a water-closet.

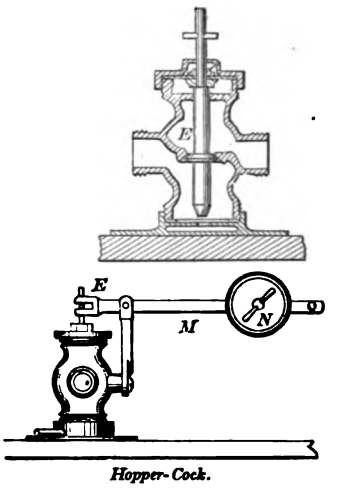
3. (*Glass.*) A conical vessel suspended from the ceiling, containing sand and water for the use of the glass-cutter.

4. (*Music.*) A jointed, upright piece attached to the back of a key in a piano-forte movement, to lift the hammer, instead of the stiff wire or lifter used formerly. It is an arrangement for allowing the key to impel the hammer and then escape from it, so that the hammer is free to fall away from the string immediately. It is a feature of the *double-action* piano-forte movement. See PIANO-FORTE.

Hop'per-boy. A device in a grinding-mill, consisting of a revolving rake drawing the meal over a discharge opening in the floor. Invented by Oliver Evans.

Hop'per-cock. A valve for water-closets, etc. In the example, pressure on the seat depresses the stem *E* with its valve, allowing the water to pass through and out of the opposite eduction opening. When the pressure is relieved the weight *N* on the lever *M* attached to the rod *E* lifts the valve again into its seat.

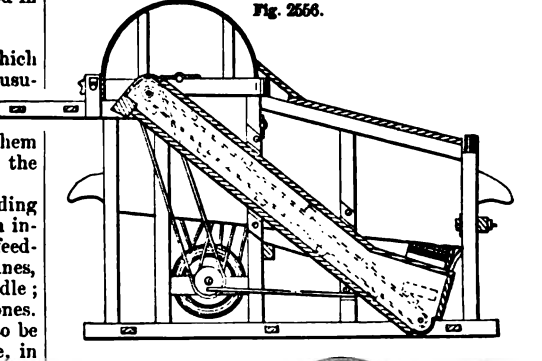
Fig. 2555.

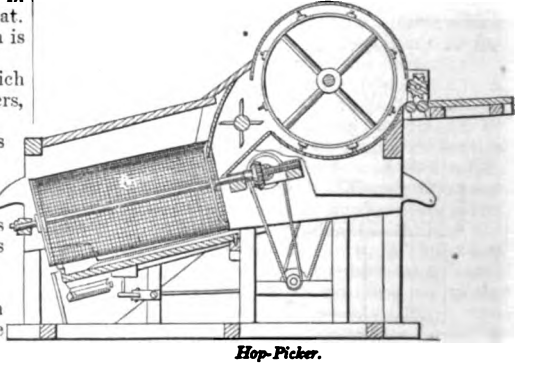


Hopper-Cock.

Hop-pick'er. (*Husbandry.*) A machine for picking hops. The branches are stripped from the vines and passed into the machine between

Fig. 2556.





Hop-Picker.

Digitized by Google

the feed-rollers, when they encounter the teeth of the picker, which detach the hops from the vines and pass both through the trough into the screen, wherefrom the hops drop into the shaker, whence they are conveyed by the elevator to sacks.

The figures are respectively a side elevation and longitudinal vertical section.

Hop'ple. (*Menage.*) A device for confining the legs of horses so as to hamper their motion and thus restrain their wandering. A *hobble.*

The devices are principally modes for shortening their step and thus reducing their speed, as well as lessening their inducement to stray, owing to the inconvenience of motion and unaccustomed restraint.

a is one intended for training. The pads are strapped around the pastern and above the knee respectively, and are connected to each other by a rubber band rove through a staple on the upper pad, and regulated as to length by the buckles on the lower pad.

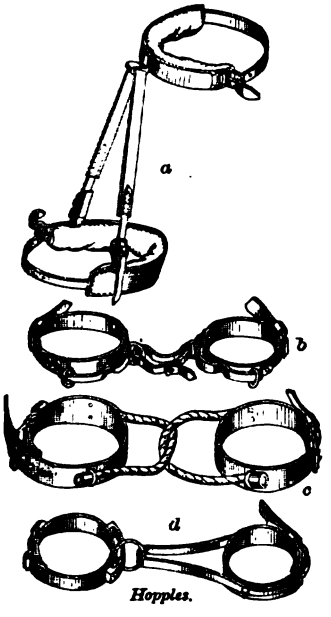
b is Captain Eagle's hopple, in which the coupling-strap ring moves in staples in the fetlock straps, and does not tend to rotate the latter and thus gall the limb.

c has coupling-loops which divide the abrasive motion between them.

d has a strap which slips through the ring instead of turning the leg-band.

Hop-pole. (*Husbandry.*) A training-pole for hops. It consists of little but a simple sapling or trunk of one of the lighter trees, the wood depending upon the means and kinds at hand.

Fig. 2557.

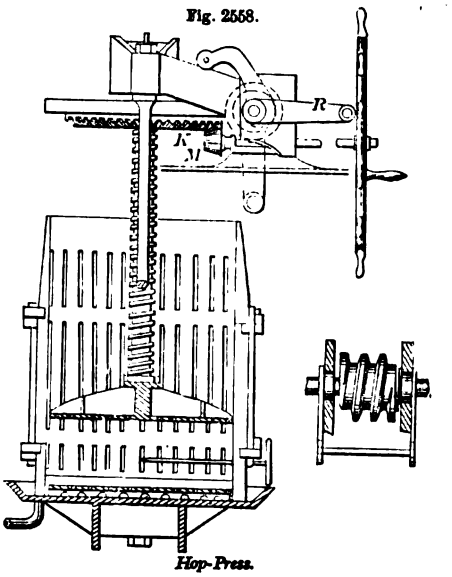


Hopples.

Hop-press. (*Brewing.*) A machine for expressing the liquid from hops after boiling.

In the press shown, a rapid rotation of the screw in the early part of the operation is obtained through the bevel gear *K M* by turning the hand-wheel. When the resistance becomes great, the hand-wheel is thrown out of gear and a worm-wheel connected, which by turning cranks *R* gives a slow but powerful impulse to the screw.

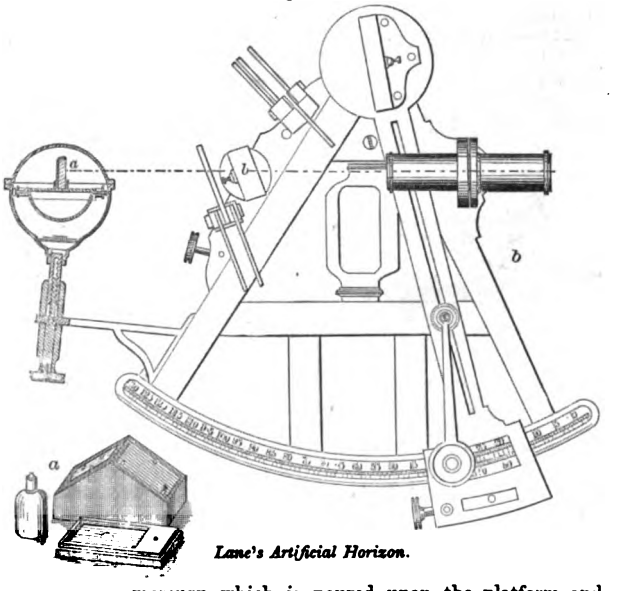
Fig. 2558.



Hop-Press.

Ho-ri'zon, Ar-ti-fi'cial. (*Optics.*) A rectangular platform (*a*, lower figure), with raised sides, and legs arranged for leveling. A glass roof protects the mercury, which is poured upon the platform and forms the horizon.

Fig. 2559.



Lane's Artificial Horizon.

Lane has a method of determining the artificial horizon for sextants, etc. To a sextant *b* of the usual construction, with an index-glass, horizon-glass, and eye-piece, is added a vertical mirror or reflecting surface *a*, the plane of which is perpendicular to a continuation of the visual ray passing from the eye-piece and intersecting a hair-line *b*, or its equivalent, which is placed in the frame of the horizon-glass, or at any point between the mirror *a* and the eye, where it can be seen by the latter, with or without the aid of a lens.

The plane of the horizon is a tangent to the cur-

Digitized by Google

vature of the earth at any place, and is assumed very nearly by the surface of a quiescent liquid, which thus becomes an artificial horizon from which the altitude — of a heavenly body, for instance — may be measured. From the law of the reflection of light, it follows that the angle subtended at the eye of an observer by a star and its image as seen reflected from such a liquid surface is twice that of the altitude of the star above the horizon. On account of its high reflecting power, mercury is the liquid generally used for an artificial horizon.

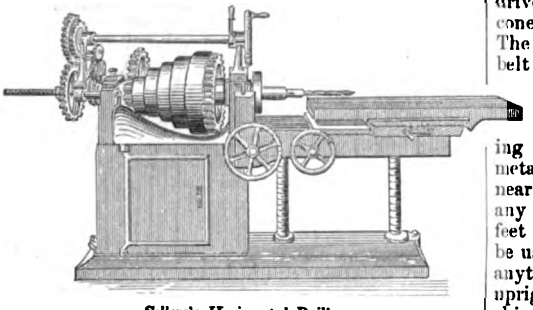
A horizontal spinning speculum was adopted by Lerson, of England, and this was improved by Smeaton, who used a polished metallic speculum about three and a half inches in diameter enclosed in a circular rim of brass, so fitted that the center of gravity of the whole shall fall near the spot on which it spins. This is the end of a steel axis running through the center of the speculum, above which it finishes in a square for the convenience of fitting a roller on it, bearing a piece of tape wound round it. It spins in an agate cup.

Ho-ri'zon-glass'es. (*Optics.*) The two specula on one of the radii of a quadrant or sextant. The one half of the fore horizon-glass is silvered, while the other half is transparent, in order that an object may be seen directly through it. The back horizon-glass is silvered above and below, but has a transparent stripe across the middle, through which the horizon can be seen.

Hor-i-zon'tal Di'al. One with a plane parallel to the horizon, having its gnomon elevated according to the latitude of the place.

Hor-i-zon'tal Drill. (*Machinery.*) A boring-machine whose drill-arbor works horizontally and parallel with the bed to which the work is dogged. It has variable feed and quick hand traverse to boring-spindle, arranged so as to be changed instantly from

Fig. 2560.



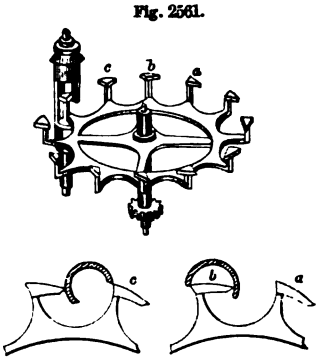
Sellers's Horizontal Drill.

one to the other; compound tables arranged to move vertically, with horizontal movement at right angles and parallel to drilling-spindle; the arbor which carries the drilling-spindle is arranged with face-plates, so that the machine can be used as a face-lathe.

Hor-i-zon'tal Es-cape'ment. One in which the impulse is given by the teeth of a horizontal wheel acting on a hollow cylinder on the axis of the balance. It was invented by Graham, about 1700.

The diagram shows the action, the cylinder being represented in two positions at different portions of its oscillation. The pallets *a b c* on the wheel rest alternately on the inside and the outside of the cylinder, their beveled edges sliding against the edges of the cylinder, to communicate an impulse thereto. It is a *dead-beat* escapement. There is considerable friction. The parts are delicate and hard to repair. The cylinder has been made of a ruby, but at great expense.

Fig. 2561.



Horizontal Escapement.

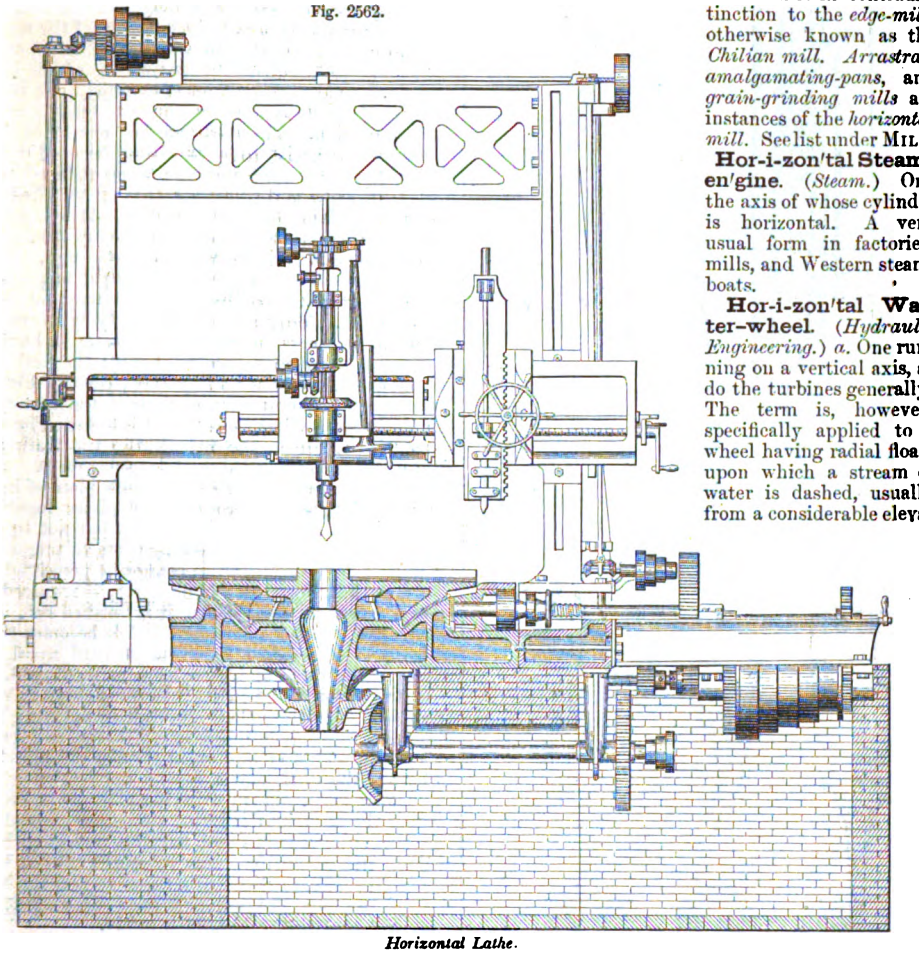
Hor-i-zon'tal Lathe. A *vertical turning and boring machine.* The one illustrated is set up in the Boston Navy-Yard, and is, perhaps, the largest in use, being of such a size that a monitor turret can be turned in it entire. The work-table, instead of traveling in slides, is circular, and revolves like a face-plate on a vertical axis. The tools are held in heads on a cross-slide, which is fitted to two uprights resting on cheek-pieces bolted to the main casting or foundation-piece.

On the under side of the revolving table is a bevel-gear driven by a pinion, which may be backed out of gear by means of a hand-wheel on a thread on the horizontal shaft. The hub of this pinion, being slightly larger in diameter than the pinion itself, is used as a journal, by means of which the pinion is caused to revolve with great steadiness, and when out of gear the pinion is within the pillow-block. This is required when a quick motion is given to the table by means of a pair of miter-gears, one of which is attached to the lower end of the table-bearing. One of the heads on the cross-slide is fitted for drilling, the spindle being 4½ inches diameter, with a travel of 18 inches, independent of the cross-slide. This drill-spindle is driven by means of miter-gears and shafting from a cone placed on the top of the upper cross-brace. The revolving table is driven by means of a 6-inch belt running on a 5-speeded cone, the smallest pulley of which is 17 inches diameter, the largest 34 inches, strongly back-geared in such manner as to allow 20 different speeds. The conical bearing of the revolving table is lined with Babbitt metal. By placing the uprights with cross-slide near the revolving table, the drill may be placed at any point within the surface of a diameter of 12 feet; while in the same position the other head may be used for the purpose of boring, facing, or turning anything of the same size. By moving back the uprights near the ends of the cheek-pieces the machine is capable of boring, facing, or turning anything up to 24 feet diameter. The main casting, in which the table revolves, is 10 feet 4 inches square by 24 inches deep, except at the center, where a projection receives the lower end of the bearing; at this point it is 9½ inches deeper. This casting weighs 26,000 pounds; weight of circular table, 13,000; weight of the cheek-pieces on which the uprights move, 14,000 pounds each. These pieces are 21 feet long, 24 inches high, 3 inches wide; the cross-slide 15 feet long, 33 inches high, deepest part of arched back 22 inches. This is cast hollow. The two uprights are connected at their upper ends by means of a cross-brace 11 feet 4 inches long by 36 inches deep. The tool-holder slide weighs 1,000 pounds, and is fitted with rack and pinion for quick movements, and screw for self-feed. The cross-slide is raised or lowered by means of screws and worm-wheel driven by power. The uprights, with the

Digitized by Google

cross-slide, may also be moved to and fro on the cheek-pieces by means of power applied to screws working in nuts at their lower ends.

Fig. 2562.



Horizontal Lathe.

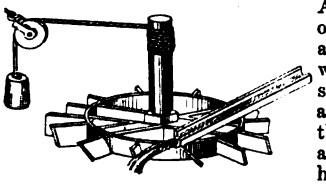
Hor-i-zon'tal Mill. A mill in which the acting surfaces are in a horizontal plane at right angles to the vertical axis of the rotating stone or stones. The term is in contradistinction to the *edge-mill*, otherwise known as the *Chilian mill*. *Arrastras*, *amalgamating-pans*, and *grain-grinding mills* are instances of the *horizontal mill*. See list under MILL.

Hor-i-zon'tal Steam-en'gine. (*Steam.*) One the axis of whose cylinder is horizontal. A very usual form in factories, mills, and Western steamboats.

Hor-i-zon'tal Wa'ter-wheel. (*Hydraulic Engineering.*) *a.* One running on a vertical axis, as do the turbines generally. The term is, however, specifically applied to a wheel having radial floats upon which a stream of water is dashed, usually from a considerable elevation. The floats may be set spirally, so as the better to receive the impact of the water.

This form of wheel has but little prominence in this country, but is used in Central America and some other places where a small body of water with a considerable head is available, and the mechanical appliances at hand will not furnish a better arrangement.

Fig. 2563.



Horizontal Water-Wheel.

b. A *turbine*, as it is usually arranged.

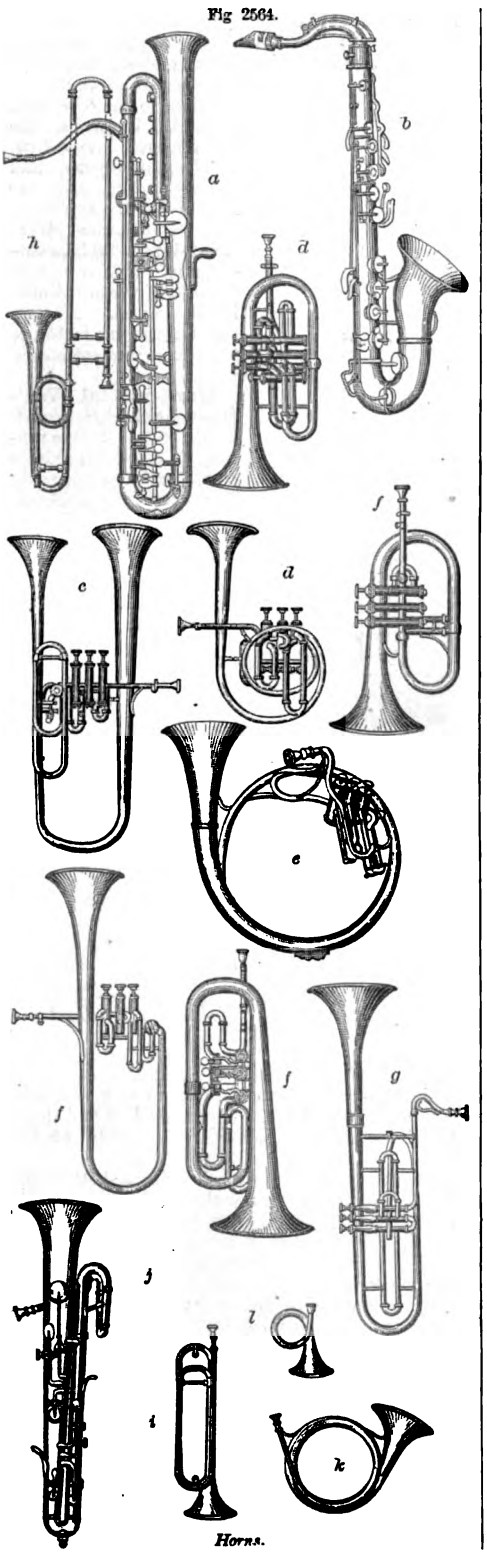
Horn. 1. A hard projection from the heads of certain animals, cattle, sheep, and goats. Mechanically and chemically speaking, the *horns* of these animals must not be confounded with the antlers of the various species of deer, which are more nearly allied to bone and ivory. The finer varieties of horn have but 2 or 3 per cent of earthy matter, while bones have over 50 per cent. If we seek for other articles nearly allied to true *horn*, we shall find them in tortoise-shell, hoofs, claws, nails, quills, whalebone.

The bony core of the horn being removed, the next process is to cut off with a saw the tip of the horn, that is, the whole of its solid part, which is used by the cutlers for knife-handles, is turned into buttons, and is applied to sundry other purposes. The remainder of the horn is left entire or is sawn across into lengths, according to the use to which it is destined.

Next, it is immersed in boiling water for half an hour, by which it is softened; and while hot is held in the flame of a coal or wood fire, taking care to bring the inside as well as the outside of the horn, if from an old animal, in contact with the blaze. It is kept here till it acquires the temperature of melting lead or thereabouts, and in consequence becomes very soft. In this state it is slit lengthwise by a strong pointed knife like a pruning-knife, and by means of two pairs of pincers, applied

Digitized by Google

Fig 2564.



Horns.

one to each edge of the slit, the cylinder is opened nearly flat.

The degree of compression is regulated by the use to which the horn is afterwards to be applied ; when it is intended for leaves of lanterns, the pressure is to be sufficiently strong (in the language of the workmen) to break the grain ; by which is meant separating in a slight degree the laminæ of which it is composed, so as to allow a round-pointed knife to be introduced between them in order to effect a complete separation. The plates are laid one by one on a board covered with hide, and being fastened down are scraped with a draw-knife ; when reduced to a proper thickness and smoothed, they are polished by a woolen rag dipped in charcoal dust, adding a little water from time to time ; they are then rubbed with rottenstone, and polished with horn shavings.

For combs, the plates of horn should be pressed as little as possible, so that the teeth may not split at the points. They are shaped chiefly by means of rasps and scrapers of various forms, after having been roughed out by a hatchet or saw ; the teeth are cut by a double saw fixed in a back, the two blades being set to different depths, so that the first cuts the tooth only half-way down, and is followed by the other which cuts to the full depth ; the teeth are then finished and pointed by triangular rasps. Articles too large to be made from a single plate of horn are made by joining two or more plates together by heating them sufficiently to melt, but not to decompose, the horn, and subjecting them to pressure ; when well done the juncture cannot be perceived.

If a work in horn, as a large comb, is required to be of a curved or wavy figure, it is finished flat, and is then put into boiling water until it becomes soft, when it is transferred to a die of hard wood, in which it is pressed, and there remains until cold.

Horn is colored by boiling it in infusions of colors. Imitations of tortoise-shell are made by applying hot a solution of pearlash, quicklime, litharge, and dragon's blood. This is laid on in streaks and blotches to imitate the shell, and a second application gives the darker spots. Horn drinking-cups are made by cutting the horn into lengths, softening, expanding the horn on a wooden mold, turning, polishing, bottoming, and mounting. The bottom is cut out by a *crown* saw, and is pushed into a groove near the bottom of the cup, the softened horn allowing it to pass, and contracting to hold it safely.

Horn for knife-handles is sawn into blanks, heated, pared, and partially shaped ; then heated in water and pressed between dies. It is afterwards scraped, buffed, and polished.

Deer-horns are worked like bone or ivory.

2. (*Music.*) A wind instrument of metal, of which many elegant and excellent instruments may be considered as varieties. The name (*horn*) suggests the article first used for the purpose : —

Bugle.	Key-bugle.
Clavicor.	Ophicleide.
Cornet.	Post-horn.
Cornopean.	Sarrusophone.
Duplex-pelitti.	Saxhorn.
French-horn.	Saxophone.
Helicon.	Trombone.
Hunting-horn.	Trumpet.
Kent-bugle.	Tuba.

The *French horn* is a brass musical instrument, of a complex, spiral form, increasing in diameter to its end or mouth. The tone is governed by pistons, or by crooks which change the pitch, and the character of the tone by the hand inserted into the mouth or *pavilion*.

Digitized by Google

The horn of the wild bull, tipped with silver and slung by a silver chain, was the *bugle horn* of the hunter in former times.

The "*echo*" attachment of the horn or bugle is a switch on one of the convolutions of the instrument, by which the sound is conducted through a small pipe, and a diminuendo effect produced, resembling an echo.

The *tuba* is a bass horn, — name from its shape.

Some of these instruments, as those marked *a*, *b*, *c*, *d*, *e*, *f*, *h*, *j*, in the accompanying cut, are made *en suite*, of sizes and compass to take different parts in concerted pieces of music, and are known as, —

Soprano.	Bass.
Contralto.	Double-bass, or
Tenor,	Contra-bass, etc.
Baritone.	

Or by the pitch of the key of the instrument, as : —

E-flat.	B-flat, etc.

The accompanying cut shows several varieties : —

a Sarrusophone.	*g* Clavicor.
b Saxophone.	*h* Trombone.
c Duplex pelitti.	*i* Trumpet.
d d cornets *à pistons*.	*j* Ophicleide.
e Helicon *à pistons*.	*k* Hunting-horn.
f f f Saxhorns.	*l* Post-horn.

3. (*Mechanics.*) A projecting portion of an object.

4. (*Saddlery.*) *a*. The high pommel of a Spanish or half-Spanish saddle. Sometimes made of horn.

b. The projections on the forward part of a woman's saddle, between which the right leg is placed. The inside one is the *small-horn*, the outer the *large-horn*.

5. (*Forging.*) The *beak* of an anvil around which objects are bent.

6. (*Nautical.*) *a*. The arm of a cleat or kevel.

b. One member of the jaw of a boom.

7. (*Mining.*) A spoon or scoop of horn, in which washings are tested in prospecting.

8. (*Milling.*) One of the points of a driver, on the summit of a millstone spindle, and which project into the *coffins* of the runner to convey the motion of the spindle thereto.

9. One of the prongs or crutches of an elevating screw or jack.

10. A curved projection on the forepart of a plane.

11. A powder-flask, of horn.

Horn, Ar-ti-fi'cial. *a*. An artificial horn for lanterns was made some 70 years since in France, consisting of brass gauze dipped repeatedly in dissolved isinglass and varnished.

b. Gelatine from bones, tanned by the ordinary process. It is used for the same purposes as horn or tortoise-shell. It is softened by boiling in a solution of potash, when it may be pressed into shape and dried between molds. It may be inlaid while in the soft state, and stained or striped to resemble fancy woods.

c. Caoutchouc, sulphur, gutta-percha, vulcanized by heat; gypsum, resin, or lead may be added, or matter for coloring.

d. Take linseed-oil 10 pounds, protochloride of sulphur 1 pound, bisulphide of carbon 3 pounds. Of the product take 10 pounds; asphaltum, 4 pounds; flowers of sulphur, 2 pounds; crude gutta-percha, 4 pounds. Put in heater and raise temperature to 300° to 350° F.

e. Horn as a substitute for whalebone : —

Boil ox-horns in water, then in oil, press while hot, and cut into shape by circular saws.

f. Towers's patent. Rawhide is dipped in melted sulphur, and molded while in a heated condition. See also PYROXYLINE; IVORY, ARTIFICIAL.

Horn-book. A primer of the fifteenth century. The alphabet, vowels, and Lord's Prayer were printed on a slip of paper, which was covered with a thin layer of horn to keep it from being torn.

Horn-card. A graduated drafting scale or protractor, made of horn.

Horn-drum. (*Hydraulic Engineering.*) A water-raising wheel divided into sections by curved partitions. It resembles one form of TYMPANUM (which see).

Horn-lead. (*Mining.*) Native chloride of lead. So called from its consistence.

Horn-mer'cu-ry. See HORN-QUICKSILVER.

Horn'pipe. (*Music.*) A Welsh wind-instrument, having a wooden pipe with holes at intervals, and a horn at each end.

Horn-plate. (*Railroad Engineering.*) The *axle-guard* or vertical frame in which an axle-box slides up and down as the springs dilate and contract. A *pedestal*.

Horn-quick'sil-ver. (*Mining.*) Native bichloride of mercury or calomel.

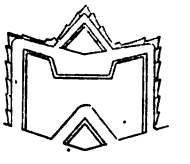
Horns. (*Mining.*) The guides for the ropes on the drum.

Horn-sil'ver. (*Mining.*) Native chloride of silver. So called from its conduct under the cutting-tool. Fused chloride of silver.

Horn-tip. (*Husbandry.*) A button or knob placed on the end of the horn of an animal of the cow kind. It is usually put on to render the horn less dangerous, sometimes for ornament.

Horn-work. (*Fortification.*) A work consisting of two *half-bastions* and a *curtain*, with two long sides called *wings*, which connect it with the main work, by which it is commanded.

Fig 2565.



Horn-Work.

It is an extended defensible position to occupy advantageous ground or to command ground otherwise unseen.

Ho-rom'e-ter. An instrument for measuring time, as a *clepsydra*, *clock*, *dial*, *watch*. See previous article.

Hor'o-scope. A species of planisphere invented by Jean Paduanus. See PLANISPHERE.

Horse. 1. (*Nautical.*) *a.* A foot-rope attached by *stirrups* beneath a yard for the seamen to stand on in reefing. A *foot-rope*.

b. A breast-rope in the chains to secure the leadsman.

c. An iron bar across a boat for a stay-sail sheet or boom-sheet to travel on.

d. A rope reaching from the *knight-head* to the upper part of the *bowsprit-cap*, for the safety of the men walking out upon the bowsprit in rough weather.

2. A wooden bar or frame with legs, used for supporting something. As a *clothes-horse* for clothes; a *saw-horse* for a board or timber while being sawed; a frame to hold a saddle; a *trestle* for joiner-work to rest upon while being keyed up.

A *shaving-horse* is a beam supported by legs, and having a *jaw* which is closed by the pressure of the feet against the treadle below, and is thereby caused to hold a shingle, axe-handle, spoke, or other article while being shaved by a *drawing-knife*.

3. (*Leather.*) The trestle or sloping board of the currier on which he spreads his skins while currying.

4. (*Printing.*) A slanting board at the end of the *bank* or table, to hold a supply of paper for a press.

5. (*Mining.*) A mass of earthy matter intervening between the branches of a vein of ore or coal. The vein straddling on each side of the non-metalliferous rock is said to *take horse*.

6. (*Hydraulic Engineering.*) That on which the mooring of a flying-bridge rides and traverses, and which consists of two masts with horizontal beams at their heads.

7. A hook-shaped tool used for hammered or raised work.

8. A vaulting-block in a gymnasium.

Horse-ar-til'ler-y. Flying artillery. Gunners mounted on horseback and on the limber.

Horse-boat. A ferry-boat moved by horses. The horse-power may be applied to paddles or to a rope stretching across the stream.

Horse-box. (*Railway.*) The English term for a horse-car used in shipping gentlemen's horses between town and country as the seasons come and go; sending hunters on to the *meet* that they may be fresh for a start; forwarding animals to exhibitions, to market, etc.

Horse-brush. (*Menage.*) One for grooming horses. Such are usually elliptical in shape, but have been made long and flexible with a handle at each end to lap around the legs.

Horse-cap'stan. A *whim*. A capstan worked by horses for raising ore, water, etc.

Horse-clip'ping Tool. A form of shears in which a pair of serrated knives reciprocate over each

Fig. 2566.

Clipping-Tool.

other, cutting off the hairs, which are cut as they come between the teeth.

Horse-col'lar. A roll of leather stuffed with straw, husk, or sponge, and placed around the neck of a horse and against the shoulder, to pull by. It has two creases to hold the hame. See COLLAR, 4.

Horse Ferry-boat. One in which paddles or a rope reaching across the river are worked by a horse on board the boat.

Horse-gear. The English term for the horse-power, applied to thrashing-machines, pumps, etc. See HORSE-POWER.

Horse-hair. The hair of the manes and tails of horses, used in making haircloth, etc. See HAIR-CLOTH.

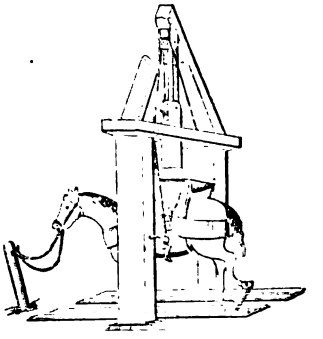
Horse Hay-fork. See FORK; HAY-FORK.

Horse-hoe. The English name for the cultivator for crops in rows. See HOEING-MACHINE.

Horse-hitch'ing Hook. (*Menage.*) A snap-hook on a short chain or strap attacked to a post or wall. The hook is snapped into the bit-ring, and the arrangement saves the trouble of carrying a hitch-strap.

Horse-hold'er. (*Menage.*) A stocks or slinging frame for unruly horses while shoeing, or for sick or disabled horses.

Fig. 2567.



Horse-Holder.

In the example, the horse is raised by a wide belly-band that is connected to and operated by pulleys above. The foot to be shod is secured to a sliding post that runs in a groove on the floor.

Horse-i'ron. (*Shipwrighting.*) A calking-iron of large size. A *making-iron*.

Horse-lit'ter. (*Vehicle.*) A palanquin or stretcher resting on poles and borne by two horses.

Digitized by Google

Horse-mill. A mill turned by a horse. See GRINDING-MILL; MILL.

Horse-nail. A nail with a thick, strong head; used in securing shoes to the feet of horses. See HORSE-SHOE NAILS.

Horse-path. (*Hydraulic Engineering.*) The *towing-path* of a canal.

Horse-power. 1. The measure of a steam-engine's power, as originally settled by James Watt. A lifting power equal to 33,000 pounds raised one foot high per minute. This was taken by Mr. Watt as the average power exerted by a mill-horse traveling at the rate of 2½ miles an hour (or 220 feet a minute), and raising a weight of 150 pounds by a rope passing over a pulley.

When a steam-engine is declared to be of such or such a horse-power, the expression must be understood in a qualified sense. Thus it is assumed that the furnace is worked in a certain average manner, and that a proportional evaporation takes place in the boiler. An engine whose nominal power is that of 100 horses may, by urging the furnace in an extraordinary manner, be made to produce an effect much greater than that of its nominal power; or, on the other hand, by keeping the furnace low, it may be, and frequently is, worked considerably under its nominal power.

For every horse-power which the engine is expected to exert, a power of evaporating one cubic foot of water per hour is provided in the boiler.

For the consumption of the fuel necessary to produce this effect, one square foot of *grate surface* per horse-power is provided.

The boiler requires 15 to 18 square feet of heating surface per horse-power. These are average estimates, the Cornish boiler and the locomotive-boiler being the extremes at each end of the scale.

Many circumstances of arrangement, the perfection with which the fuel is burned, the draft, mode of feeding, character of coal, etc., modify these results.

The power of water-wheels, etc., is expressed in horse-power.

Mr. Tredgold compiled a table showing the maximum quantity of labor that a horse of average strength is capable of performing at different velocities, in drawing *boats* on *canals*, and carriages on railways and turnpike-roads respectively: —

Velocity in Miles per Hour.	Duration in Hours of the Day's Work at preceding Velocity.	Force of Traction in Pounds.	Useful Effect of One Horse working One Day in Tons drawn One Mile.		
			On a Canal.	On a level Railway.	On a level Turnpike.
2½	11½	83⅓	520	115	14
3	8	83⅓	243	92	12
3½	5 9/11	83⅓	153	82	10
4	4½	83⅓	102	72	9
5	2 1/9	83⅓	52	57	7.2
6	2	83⅓	30	48	6
7	1½	83⅓	19	41	5.1
8	1⅛	83⅓	12.8	36	4.5
9	1/9	83⅓	9	32	4
10	¾	83⅓	6.6	28.8	3.6

The average force exerted by a horse at a plow, at a rate of 2½ miles per hour, and with an exertion which he is capable of sustaining for the usual hours per day and every working day, as deduced from dynamometrical experiments at eight plowing-matches, at each of which from 5 to 7 teams were employed, was 163 pounds.

The number of horses subjected to the test was 144, and the observations were made by Mr. Bevan at Woburn and Ashridge, under the observation of some distinguished agriculturists.

In connection with the subject of *horse-power*, it may be well to notice that the terms *power* and *duty* are not synonymous, but opposite, terms.

Power means the quantity of work that can be performed in a given time.

Duty signifies the amount of work that can be performed with a given expenditure of fuel.

To obtain the full amount of *power*, the steam is worked at full pressure the whole of the piston-stroke.

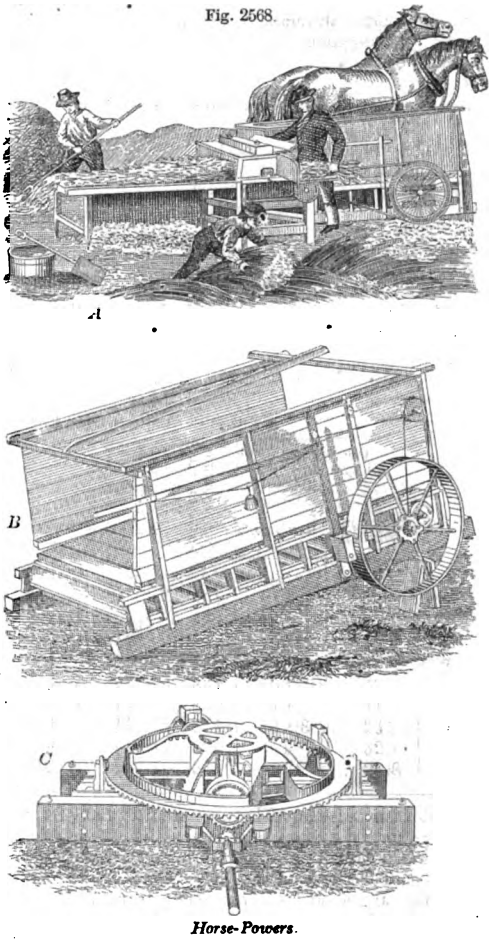
To obtain the highest *duty*, it is used expansively.

A cheap engine, unprovided with the expansion arrangement, will exhibit a greater power than a more expensive engine worked expansively, other things being equal; but the latter will be the more economical in running.

To repeat: power has no reference to the quality of an engine, but to the capacity of its cylinder in connection with a stated pressure of steam. Economy or waste of steam in working does not enter into the question.

Duty disregards time, and the size or power of the engine. It merely inquires how much work is done by a given expenditure of fuel. See CUT-OFF; DUTY.

Fig. 2568.

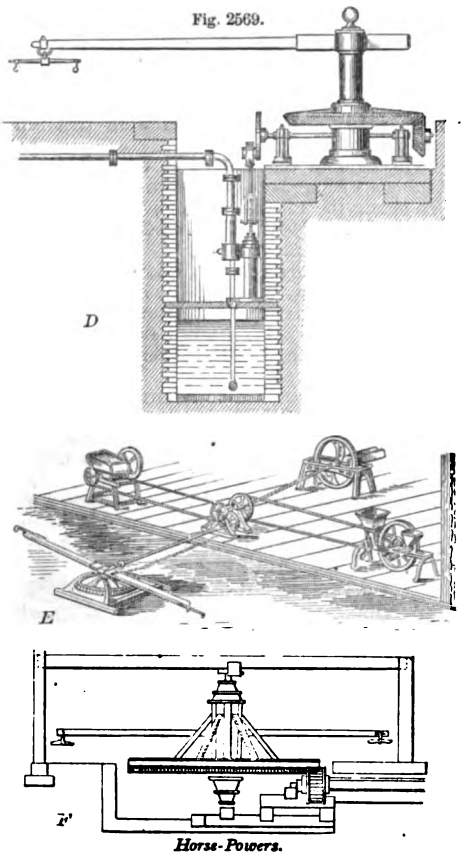


Horse-Powers.

2. A machine in which the power of horses is exerted to drive other machinery.

Digitized by Google

Fig. 2569.



Horse-Powers.

A (Fig. 2568) is one which the horses walk upon a traveling platform, which slips beneath their feet as the animals pull upon a bar at the rear of the machine. It is shown in connection with a small thrashing-machine.

B is a similar machine without its tenants, and exhibiting the parts more clearly.

C is an ordinary horse-power, such as is used for thrashing-machines, drag-saws, clover-hullers, and corn-shellers. It is dismounted from the wagon, secured by stakes and chains, and levers placed in the sockets, which in this case are four in number, intended for two horses to each lever.

The diameter of the path should be 25 to 30 feet. The horse works to best advantage at 2½ miles per hour of 220 feet in a minute. The force is estimated at 22,000 pounds raised one foot high per minute, which is 66 per cent of the power exerted in drawing in a direct line.

D (Fig. 2569) is an arrangement of horse-power for working a pump.

E is an arrangement for driving a cutting-box, grinding-mill, and corn-sheller, for either of which a hominy-mill or apple-grinder may be substituted when desired.

F is an English arrangement, in which the crown-wheel drives a lantern pinion.

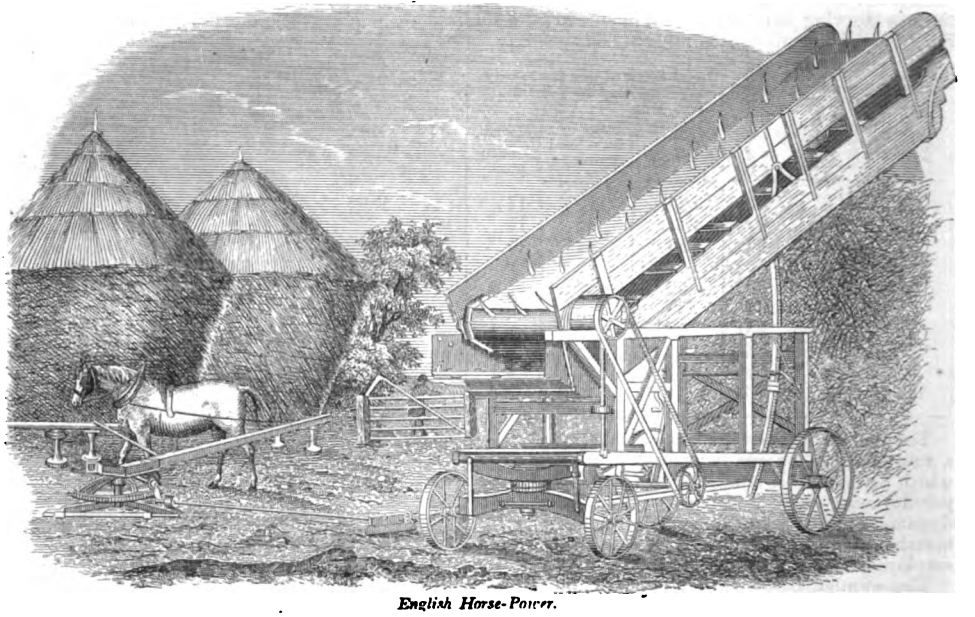
Fig. 2570 shows the English horse-power as applied to a straw-stacker, placed at the delivery end of the straw-carrier of a thrashing-machine. It has a master-wheel and pinions, and the power is conveyed by belting and shafting to an endless apron with tines.

Fig. 2571 shows an American mounted horse-power, that is, one which is used without dismounting from the wheels, by which it is moved from place to place. Power can be applied from both sides and both ends at the same time, or from either point alone, as desired. *U* are the levers to which the horses are attached; *C* is the master-wheel, driving the pinions on shaft *F*, which carries the wheels *D G*; the latter convey motion to the pinions on the inner ends of the tumbling shafts.

Horse-rail'road. A railroad for city or suburban use, whose cars are drawn by horses.

The first railroads were in mines, and for carrying

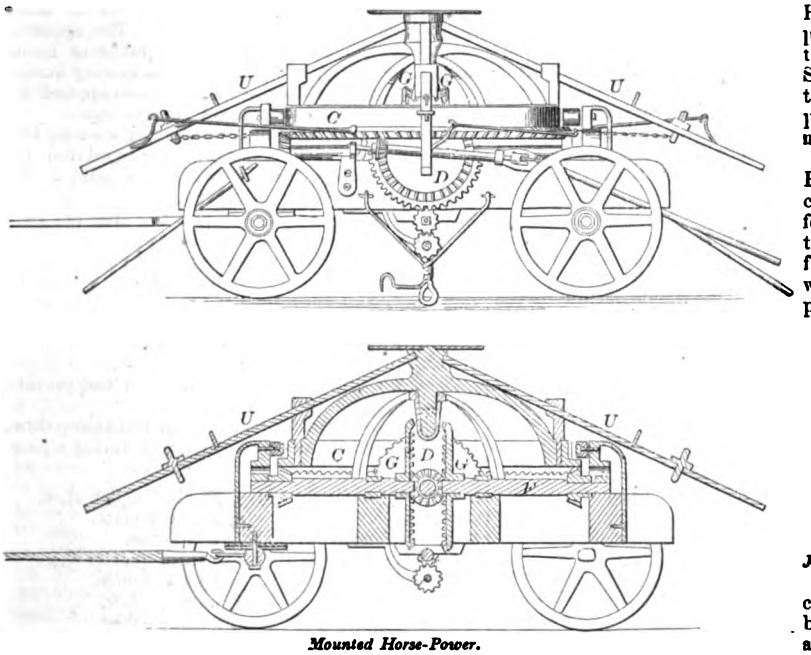
Fig. 2570.



English Horse-Power.

Digitized by Google

Fig. 2571.



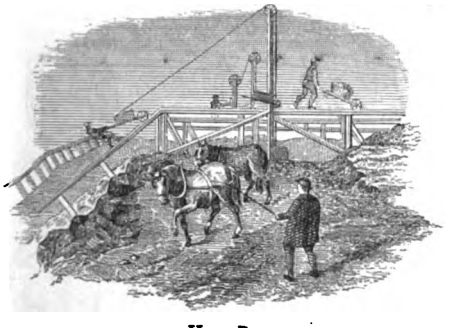
Mounted Horse-Power.

coal to the seaboard. These are yet, many of them, worked by horse-power. See RAILWAY; STREET-RAILWAY; LOCOMOTIVE.

Horse-rake. A hay or stubble rake drawn by horse-power. See RAKE; HAY-RAKE.

Horse-run. A device for drawing loaded wheelbarrows up an inclined plane in making excavations.

Fig. 2572.



Horse-Run.

It consists of a rope passing over two pulleys. The horse is hitched to the fall and the wheelbarrow hooked to the other end of the rope.

Horse'shoe. 1. (*Menage.*) Horses were not shod in Egypt, Assyria, or Palestine. The latter country was supplied with horses by the Egyptians. Solomon paid 150 shekels of silver, equal in value to $75, for each horse. This was a high price, the difference in relative value of the shekel and a given weight of wheat, meat, or other necessary, being considered.

Isaiah speaks of horses whose "hoofs shall be counted like flint," — a valuable quality where they were shoeless.

The Syrians and Hittites were supplied with Egyptian horses by Solomon, who turned an honest penny by this means.

Aristotle and Pliny mention the covering of horse's feet in stony places to protect the hoof from breakage and wear, but it is probable that such

Fig 2573.

Japanese Horseshoe.

covering was a bandage or boot, and was used principally on long journeys. Suetonius refers to the dismounting of Vespasian's muleteer to shoe his mules. Wrappings of plaited fiber, such as hemp or spartium (broom), were used, as was also leather.

In Japan the horses have clogs of twisted straw, of which a large supply is carried on a journey. When worn, another is immediately applied. Our plan would no doubt appear a barbarous custom in their minds. The Siberians and Kamtschatkians use traveling-socks for their dogs. Captain Cook refers to them.

Camels in old times were similarly provided, as we learn from Aristotle and Pliny. These boots were drawn on over the feet, and it does not appear that iron or other metallic plates were nailed to the hoofs. Such boots were shod with metal for the rich. The mules of Nero were shod with silver; those of his wife Poppæa with gold. Xenophon, Arrian, Artemidorus, refer to these boots. For less stately purposes mules were shod with iron.

"Ferream ut soleam tenaci in vargine mula."
CATULLUS.

Homer mentions brazen-footed steeds (Iliad, VIII. 41, and XIII. 24), probably a merely metaphorical expression implying strength. Mithridates and Alexander experienced great difficulty with their cavalry, owing to the soreness of the unprotected feet of the horses in long marches. Pollux, in his dictionary, does not mention horseshoes of metal. The first certain mention of shoes nailed to the hoofs is in the works of the Emperor Leo, ninth century. The practice of shoeing horses is said to have been introduced into England by William I.

The principal parts of a horseshoe are: the two *faces*, upper and lower; the two *edges*, inner and outer; the toe, or front part; the *quarters*, between the toe and the heels; the *calks*, projections from the lower part of each heel; steel calks are also frequently added to the toe; the *fullering*, or crease in the lower face, in which the nail-holes, generally

Digitized by Google

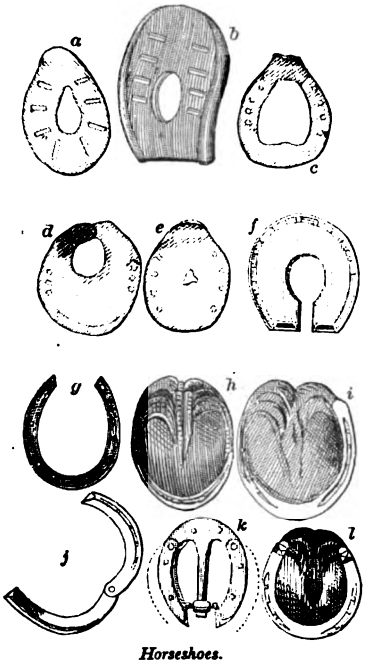
eight, are made ; the *clip*, a kind of claw, usually at the upper edge of the toe, for protecting the hoof and assisting to keep the shoe in place.

The upper face is beveled, or made slightly concave, to prevent the iron from resting on the arch of the sole of the foot.

Horseshoes made by machinery are now generally employed. They are made of five sizes, and are numbered from 1 to 5, the first being the smallest and the latter the largest. Nos. 3 and 4 are those most commonly required.

"In two respects," says Loudon, "the shoeing of Holland differs from ours. 1. To prevent splitting, the fore hoofs are pared away at the toe, and the shoe so fitted that the toes do not touch the ground when the foot stands flat ; the weight resting on the middle and the heel of the shoe. 2. The shoe is nailed on perfectly flat and close to the foot, which is flattened to receive it ; the iron is thereby deprived of all spring, and the hold of the nails is un-

Fig. 2574.



Horseshoes.

disturbed." The frog comes in contact with the ground. This mode of shoeing may not commend itself to our farmers and teamsters, but the Dutch have good horses, use them well, work them hard, and their practice is worth considering.

A *bar-shoe* is one in which the shoe is continued round below the heel. It is used on hoofs liable to contraction at the heel, its purpose being to keep them spread.

A *stifle-shoe* is one with a round bar, convex side downward, giving it an unsteady foundation on the ground. It is placed on the foot of the *well* hind leg, so as to compel or induce the animal to throw the weight of the hind quarters on the other foot to reduce the luxation or weakness at the stifle-joint of the leg.

In 1810, Rotch obtained an English patent for an elastic horseshoe, consisting of a sheet-iron sole attached to an india-rubber upper, which was slipped upon the foot, clasping the crown and encircling the pastern. A regular shoe was riveted to the sheet-iron sole of the boot when required. The *upper* or caoutchouc band was prolonged upward as far as deemed necessary, and, in case of *interfering* horses, was made to cover the fetlock. He also applied the caoutchouc bands to the knees, as *knee-caps*.

Charlier substitutes for the ordinary shoe an iron band, let into a rectangular groove scooped from the outer circle of the horse's foot. This band is fastened with seven rectangular nails, driven into oval holes. The soles of the foot and the frog are thus allowed to touch the ground.

Dudley's *cast-iron* horseshoe, English patent, 1823, was cast in a mold modeled from the foot of the horse, and subsequently rendered malleable in a furnace.

Besides the construction of the shoe proper, there are certain attachments thereto, such as, —

Snow-pads, which fit within the shoe and prevent the accretion of snow or ice therein.

Movable calks, which may be attached at any time, if the ground freeze or become sleety during a journey.

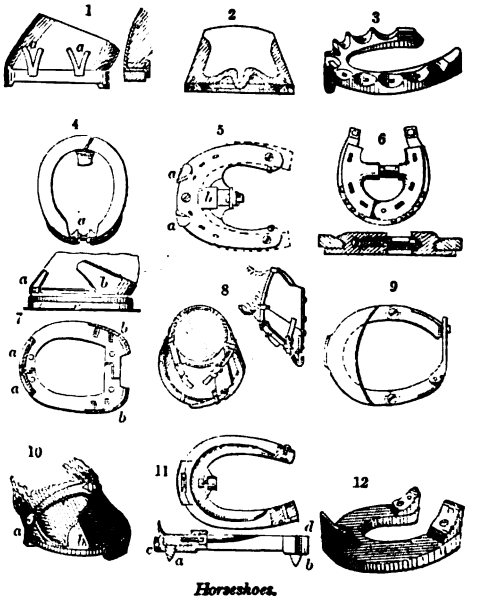
a represents an early Arabian shoe.
b, an Arabian shoe of modern date.
c, a Moorish shoe.
d, a Persian shoe.
e, a Portuguese shoe.
f, an old English shoe.
g, a racing-plate.
h, a tip-shoe.
i, a three-quarter shoe.
j, a jointed shoe.
k, a screw-shoe.
l, a calked shoe.

Fig. 2575 illustrates various horseshoes.

1. The bifurcated springs *a a* clip the hoof, and are attached to the shoe by bolt and nut.

2. Countersunk-headed screws parallel to the wall of the hoof are employed for fastening the shoe.

Fig. 2575.



Horseshoes.

3. Ridges and indentations are formed upon the sole of the shoe. Goodenough's horseshoe has an indented ridge on its under side, perforated for the insertion of nails.

4. For contracted hoofs. By means of the screw

Digitized by Google

a and nuts between the heel-clips the branches of the shoe may be spread and maintained the proper distance apart.

5. A supplemental roughing shoe is attached to the upper shoe by clips *a a* and a sliding screw-block *b*. Pins at the rear prevent lateral displacement.

6. The shoe is hinged at the toe, and is designed to be permanent. It is beveled on its upper inner edge, to receive the flange of a removable false shoe, that is expanded outwardly by a screw, so as to fit snugly to the permanent shoe, and sustain all the wear.

7. A double-shoe. The upper one is hinged at the toe, and has a jointed cross-bar at the heel; curved clips *a a b b* fit the walls of the hoof and secure the shoe in place. To this the lower plate *c* is secured by screws.

8. The shoe is attached to the hoof by pieces of leather at the front and quarters secured by connecting straps.

9. The shoe has a toe-cap, is jointed at the sides, and has clips and pivoted catch or connecting bar at the rear, dispensing with nails.

10. Rear clips *a*, toe-cap *b*, and strap *c*, held by a button on the toe-cap, hold the shoe to the hoof.

11. The removable toe and heel calks *a b* are dovetailed into plates *c d*, which are fastened to the shoe by screws.

12. The toe and heel calks are adjustably fastened to the shoe by screws.

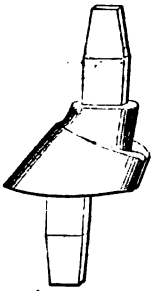
See Fleming's "Practical Horseshoer"; "Rational Horseshoeing," N. Y., 1873.

Refractory animals are confined in a *brake* while shoeing. The brake for cattle is represented under OX-SHOES (which see). The brake for horses consists essentially of an arrangement of straps to bear the weight of the animal, and to prevent his lunging forward, backward, or rearing; also of posts or bars to which his hind or fore feet are lashed while shoeing.

2. (*Lathe.*) A movable support for varying the gearing and the velocity of the screw which moves the slide.

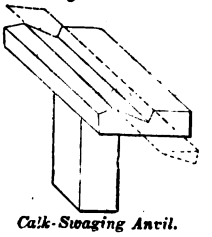
Horse'shoe-an'vil. One which corresponds in shape and size to the hoof of a horse, and has shanks

Fig. 2576.



Wilkinson's Anvil.

Fig. 2577.



Calk-Swaging Anvil.

which permit its adjustment in the socket-hole of the anvil, in either a natural or a reversed position. It affords a means of making and fitting the bands and clasps by which the removable horseshoes are attached, in place of nails.

The calk-swaging anvil has a groove across its face, in which a bar of metal is swaged to the level of the plane surface of the anvil, thereby acquiring a triangular shape in cross-section, and forming a rod from which sharpened calks may be cut.

See ANVIL, pp. 121, 122.

Horse'shoe-clamp. (*Shipbuilding.*) An iron strap by which the *gripe* and *fore-foot* are attached. See STEM.

Horse'shoe-ma-chine'. A machine in which bar-iron is converted into horseshoe blanks or horseshoes.

Burden of Troy, New York, patented a machine for this purpose in November, 1835, which had segmental reciprocating dies to shape a straight blank by giving it the requisite thicknesses at the respective parts, and the creases for the nail-heads. The piece rested on a rocking anvil-bed. His patent of September 10, 1843, described a reciprocating rectilinear movement, cutting off from a heated rod a straight blank and impressing by dies, which made the fullering and nail-holes. His patent of June 20, 1857, was reissued June 3, 1865, and extended in 1871. In it the motions are rotary and continuous. The red-hot bar is introduced at the side of the machine, and a sufficient piece cut off by a descending cutter. It passes between guides to a stop, and is held in place till a bending-piece on a roller comes against it and carries it along. This piece corresponds to the inner shape of the shoe, and with this as a former the blank is carried past a series of dies which press it to shape, thinning the inner edge, thickening the heels, pinching in the heels, making the creases by dies and the nail-holes by punches, in succession. After flattening, the shoe is dropped from the machine.

Other forms of machines have circular beds, carrying formers which pass the blank between dies which act successively upon the edges and face to give the required proportions and contour, as well as the creases and nail-holes.

Another form pinches the heated blank between a center former and two posts, while top rollers shape it vertically and side rollers lap the heels around the receding portion of the former, which acts as a die.

In another, the bar is fed in between the shears until it butts against the adjustable gage-plate. Being severed by the shears, the bender advances and drives it between a pair of rollers, giving it a proximate horseshoe shape. The heels of the shoe fall into a depression, and as the bender retires the shoe is drawn from it. The creasing and nail punch are on an oscillating lever, and the latter acts upon and in conjunction with a lower lever, which perfects the perforation.

In one rotary form of machine, the *former* which carries the blank is rotated first between two friction rollers placed on and under a stationary bridge, then under a reducing-roll, a guide-roll, finishing bending device, and hammering-rolls, the shoe being discharged by a pin thrown up by a cam.

Horse'shoe-mag'net. An artificial iron magnet of a horseshoe form.

Horse'shoe-nail. A nail made of superior soft iron and used to fasten on horseshoes. It has a flat pointed tang, and a relatively heavy countersunk head. See NAIL.

Lengths of horseshoe nails:—

No. 5.	1½ inches.	No. 8.	2 inches.
No. 6	1¾ "	No. 9	2¼ "
No. 7.	1⅞ "	No. 10.	2½ "

Horse'shoe Nail-ma-chine'. One in which rods of iron are shaped into nails for the purpose stated.

In one form of this machine, the nail-rod is fed downward through a heating furnace in front of a stationary anvil by means of a cam geared to make one movement. As each finished nail is cut off at right angles to the face of this anvil, two sliding hammers, having faces of the contour the reverse of the sides of the finished nail, are forced against the sides of the blank simultaneously by means of

Digitized by Google

springs; a third hammer works perpendicularly to the face of the anvil, alternately with the other two, by which the nail is forged. When the nail has been sufficiently hammered, it is cut off by a knife moved against it at the top of the anvil by a cam.

In another, the nails are made directly from the rod by a continuous operation, the blank from which the nail is to be made being first cut from the rod and then passed successively through a series of revolving dies operating in pairs, by which it is gradually drawn down and finished.

Horse'shoe-rack. (*Nautical.*) A sweep curving from the bitt-heads abaft the mainmast carrying a set of nine-pin swivel-blocks, as the *fair-leaders* of the light running-gear, halliards, etc.

Horse-tail. 1. Dutch rush, used for scouring.

2. A Turkish standard, the number indicating the rank of a commander.

Hors'ing-block. A frame to raise the ends of wheeling-planks in excavating.

Hors'ing-i'ron. (*Nautical.*) A calker's chisel attached to a withy handle, and used with a beetle in driving oakum into a vessel's seams.

Hors'ing-up. (*Shipwrighting.*) The final driving of oakum into the seams between the planking of ships. See MAKING-IRON.

Hose. 1. Flexible tubing, usually for the conveyance of water, especially for fire-engine service. Smaller hose is used for street-watering, for gas service with drop-lights, for acoustic instruments, stems of hubble-bubbles, hookahs, etc.

Various are the materials: —

Fabric covered with leather.

Wire, cement, and intestine.

Paper saturated with paraffine.

Fabric saturated with carbolic acid and copper salts.

Woven tubes of fibrous material saturated with caoutchouc; or treated with corrosive sublimate, chloride of lime, pyrolignite of iron, resinous materials.

Fabric coated or lined with caoutchouc or gutta-percha in solution.

Leathern hose, treated with beeswax, linseed-oil, and pitch.

Rings or spiral twist of hard-rubber, in or outside of hose, and vulcanized all together.

Internal and external rubber tubes; intervening concentric, seamless tube, woven or braided; all vulcanized together.

India-rubber or gutta-percha tube, around which is woven or braided a netting of cord, yarn, or wire.

Hose is made by longitudinal extension through dies, or of a seamless fabric by knitting or braiding, by winding in spiral slips, or by lapping around a mandrel as long as the sections, which are afterwards coated. Different materials require various treatment.

Another mode of making hose is by feeding a tube of fabric, leather, or other material, through systems of revolving bobbins, which braid upon the tube a cord or twine covering. See Fig. 2584.

Fig. 2578 shows a number of kinds of hose, the differences being in the modes of winding, joining, material, character, and succession of the folds, etc.

a is a flexible hose of woven and lapped tubes and water-proof linings.

b is a similar hose with the waterproof material as a coating.

c is a flexible pipe made of woven fabric with a water-proof lining, and riveted.

d, a tube of rubber or gutta-percha, or of fabric coated with the gums, closely wound with twine.

e, a hose made of two or more concentric seamless tubes of fiber, the inner one lined with caoutchouc.

f has a cemented strip over the seam.

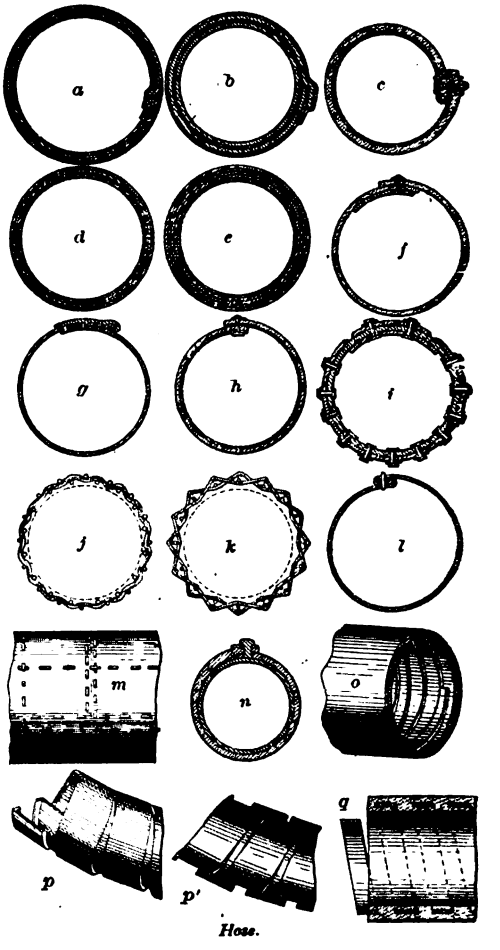
g is stitched through and through with several rows, and the sections joined with diagonal rows of stitches. A welt covers the outside of the join.

h has a fibrous covering, rubber lining, and riveted junction.

i has a double row of rivets along the seam, and a spiral doubly riveted welt lapping the oblique junction of sections.

j is made of strands of fibrous material soaked in

Fig. 2578.



Hose.

gutta-percha or rubber cement, and then woven or braided.

k, an outer tube of wire or twine, is woven or braided upon an inner tube or lining.

l, hydraulic hose whose meeting edges are interlocked so as to present a fourfold thickness to the rivets.

m has a lapped seam sewed with leathern thongs.

n is leathern hose with a spiral metallic lining.

o is a suction-hose having a spirally laid flat wire lining and a seamless textile fabric covering treated with waterproof material.

p p' are two views of a suction-hose showing a stiffener made of two spiral bands which engage

Digitized by Google

each other by means of inward and outward flanges.

q is a vulcanized rubber suction-hose composed of an exterior body, an interior lining, and an intermediate spirally coiled metallic strengthening rib.

Flax or hempen hose woven without a seam, and payed with waterproof material, was used generally on the continent of Europe previous to the introduction of india-rubber hose.

Leather was used in England and in the United States, and still maintains its ground for some purposes. Leathern hose was first sewn with waxed twine, then copper wire was substituted, and finally riveting.

Leathern hose, made in detachable sections, for application to fire-engines, was invented by Heide, a Dutchman, in 1672, and was common in the Netherlands soon after.

The spiral coil of wire inserted throughout the length of suction-hose, to keep it from collapsing, was used with the Newsham fire-engine, London, about 1780.

Rubber hose is made by wrapping RUBBER-CLOTH (which see) around a tube of the required size, the number of plies depending upon the required strength. The tube is then placed in a heater and subjected, for a sufficient time, to a steam pressure of 80 pounds to the square inch = 289° F., which melts the sulphur and vulcanizes the gum.

The tube is then withdrawn from the hose.

Or a sheet of rubber wrapped on a tube and covered by several webs of cloth, saturated with prepared rubber, and eventually by a sheet of rubber. The hose, when formed, is taken to a steam-boiler of great length, where, while still remaining upon the iron pipes, it is heated and cured by a process similar to that before described; after which the rubber is drawn off from the pipe, and it is ready for the market.

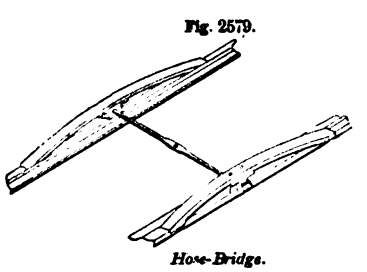
Among the earliest mention of hose is the following passage in Herodotus (450 B. C.). It refers to the mode of watering the hosts of Cambyses the Persian, during his passage of the desert to attack Psammenitus, the son of Amasis, the Pharaoh of Egypt: —

"There is a great river in Arabia, called the Corys, which empties itself into the Erythræan [Red] Sea. The Arabian king, they say, made a pipe of the skins of oxen and other beasts, reaching from this river all the way to the desert, and so brought the water to certain cisterns which he had had dug in the desert to receive it. It is a 12 days' journey from the river to this desert tract. And the water, they say, was brought through 3 separate pipes, to as many different places." — Book III. c. 9.

He adds that it is an improbable story, but that he will not pass it by altogether. The *idea* certainly, so far as we are concerned, is as old as the recorder, who wrote about 2300 years ago.

2. (*Printing-press.*) A case connected by hooks with the platen, for guiding and raising it.

Fig. 2579.



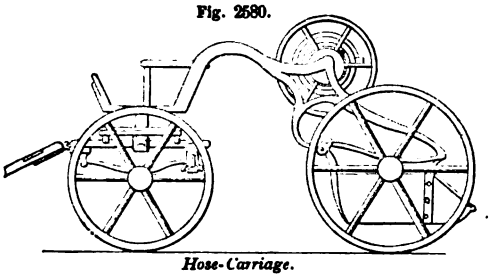
Hose-Bridge.

Hose-bridge. A bridge for carriages or street-cars to allow them to cross fire-engine hose laid in the street.

One form of it was patented by Demarest in 1853. The example shown is to bridge hose which lies across a street-railway.

Hose-car'riage. A reel on wheels to carry hose for fire-engine service. In the example, a fuel-box

Fig. 2580.

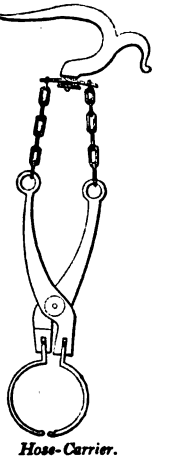


Hose-Carriage.

for the boiler-supply is supported on the same frame. The front wheels turn beneath the elevated perch.

Hose-car'ri-er. A tongs for gripping hose in *lighting up* full hose when in service.

Fig. 2581.



Hose-Carrier.

Hose-coup'ling. A joint-piece or pair of interlocking connecting pieces, by which ends of hose-sections are joined together in line. There are many forms.

a has a swivel which fits against a collar on the nipple, and its flanges are engaged by the sleeve, which also screws upon the back screw on the other nipple, pressing the ends of the sections against the intervening annular packing.

In *b*, the segmental rib and projected screw-block of the outer coupling-piece enter a circumferential groove of the other piece.

In another ordinary form, the sections of hose are bound with wire, or thimbles upon collar-pieces, one of which has a threaded exterior and the other a threaded sleeve, which screws upon the former. A *spanner* or wrench is used to tighten the connection.

In *c*, a portion of the threads on the screw and socket are cut away to enable the parts to be slipped past each other, and lock by a partial revolution, when the undivided threads catch and complete the joint.

d. The two parts are slid together and the pins enter their respective grooves at the opposite sides; the handle is then turned, and the cam-head locks the parts together.

e. The packing-ring is formed to enter two rectangular annular grooves in one part of the coupling and a V-shaped annular groove in the other part.

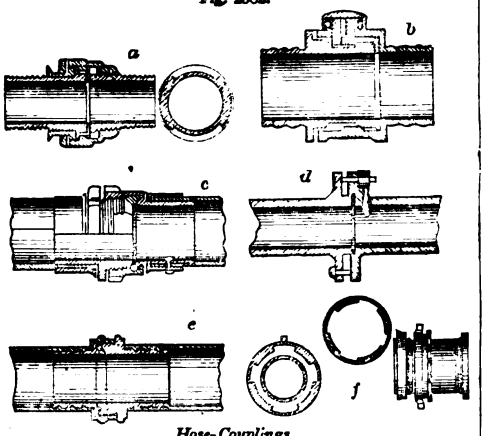
f. The projections on the outer cylinder interlock with a groove in a collar on the inner cylinder. Expansible packing is enclosed between collars and is forced against the outer cylinder by compression. The hose is brought over the convex, circumferentially grooved ends of the coupling and confined by a screw-threaded ring.

In the Westinghouse coupling for air-brake pipes of railway-cars, the parts are connected by a spring-

Digitized by Google

hook fastening. Each half-coupling contains a puppet-valve which seats outwardly. Guiding wings

Fig. 2582.



Hose-Couplings.

are made on the valve-stems, and the stems project outwardly such distance that when the hose are coupled up, the stems, coming end to end, will each unseat the other valve. Hence, when the couplings are united, the valves will always be open, and *vice versa*. See BRAKE.

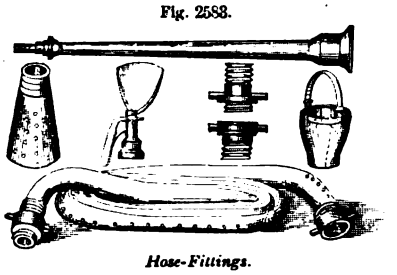
Hose-fit'tings. The various parts by which hose are attached section to section, or a section of the hose to the engine or the nozzle.

The nozzles are of various kinds. The cut shows,—

A *branch-pipe*, with *jet* or *nozzle*.

A *strainer* for the end of the supply or *suction hose*, which is let down into a cistern.

Fig. 2583.



Hose-Fittings.

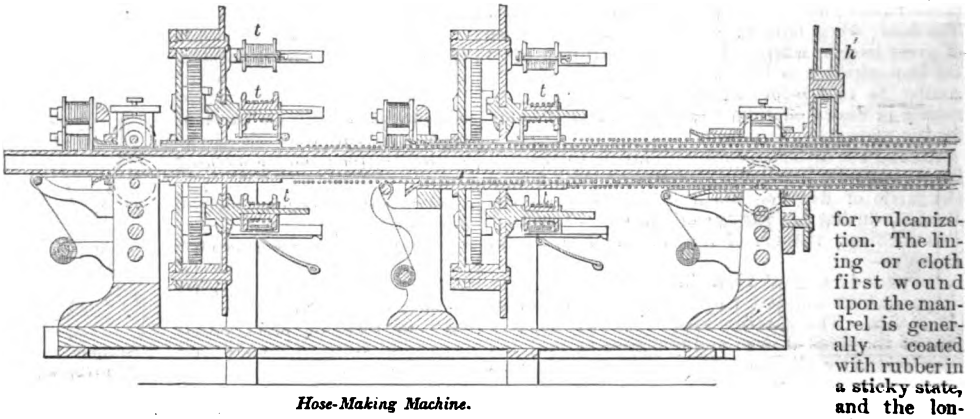
A *spreader* jet.

Couplings or *hose-unions*.

A leathern fire-bucket. These are also made of canvas or galvanized iron.

A section of leathern hose, copper riveted, and having coupling sections at each end.

Fig. 2584.



Hose-Making Machine.

Hose-hooks. 1. The hooks by which the platen of a printing-press is suspended.

2. A tongs for carrying hose. See HOSE-CARRIER.

Hose-jump'er. For street railroads. A *hose-bridge*.

Hose-mak'ing Ma-chine'. A machine for winding or weaving a flexible tube of textile and rubber fabrics.

Fig. 2584 shows a machine adapted to this purpose. A layer of rubber, or cloth saturated with rubber, is wound around a mandrel which extends the full length of the machine. As the fabric moves along from left to right it is wound with thread or wire from the first set of bobbins *t t*. Before it reaches the second set of bobbins for another coating or *ply*, it may receive a set of longitudinal cords, threads, or wires from the intermediate reels. It is then again wound by the second set of bobbins *t t*, and finally receives a coating of cloth, tin-foil, or other material from the spool *h'*, and is then ready for vulcanization. The lining or cloth first wound upon the mandrel is generally coated with rubber in a sticky state, and the longitudinal or transverse binders may be so coated, or saturated with rubber. See INDIA-RUBBER.

Hose-protect'or. A hose-bridge to enable vehicles to cross hose without compressing or cutting it. See HOSE-BRIDGE.

Hose-reel. 1. A carriage to carry hose for the service of a fire-engine. See HOSE-CARRIAGE.

2. A reel to carry hose for garden, stable, or other domestic uses.

Fig 2585.

Reel for Garden-Hose.

Digitized by Google

Hose-shield. A hose-protector. See HOSE-BRIDGE.

Hose-trough. (*Blasting.*) A wooden tunnel for the powder-hose to fire the charges of mines.

Hos'pi-tal-wag'on. A carriage on four wheels, having four or six springs, used for carrying the wounded of an army. An *ambulance*.

A wagon carrying surgeons' supplies and instruments, or bedding, food, and other supplies for a field hospital. The Prussian hospital-wagons are fitted up with combination cases, in which are packed everything supposed to be necessary in a hospital for wounded, including bandages, splints, drugs and anæsthetics, blankets, and an amputating-table, besides an assortment of tags, on one of which the surgeon writes his orders as to what is to be done in each case, attaches it to the patient, and leaves him to the care of others. Five ambulances, three supply-wagons (carrying food, bedding, and tents), and two surgeons' wagons constitute a hospital train for a division, and will accommodate 200 patients, requiring 13 surgeons and 74 men for their care.

Hot-air En'gine. One driven by the heating of a body of air admitted to the cylinder. They are of two kinds: —

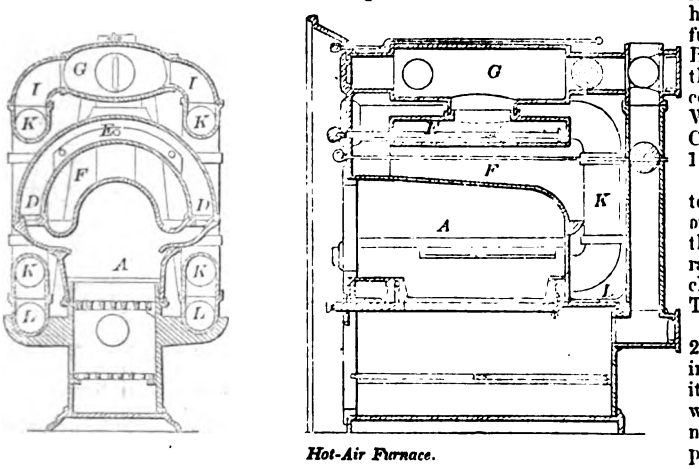
First, those which draw their supplies directly from the atmosphere, and discharge them into the atmosphere again after they have produced their effect. Such are the Ericsson, Stillman, Roper, Baldwin, Messer, Wilcox engines, described on pp. 40 – 43. See also Dr. Barnard's report on the French Exposition, pp. 34 – 40, and plate 1.

Second, those which employ continually the same air, which is alternately heated and cooled, but which is not allowed to escape. Such are the Glazebrook (1797), Parkinson and Crosley (1827), Laubereau (1849), Schwartz, described on pp. 43, 44.

These and other distinguishing features are described under AIR-ENGINE (which see).

Hot-air Fur'nace. One in which air is heated for warming houses, or for purposes of drying, usually the former. The arrangements are various,

Fig. 2586.

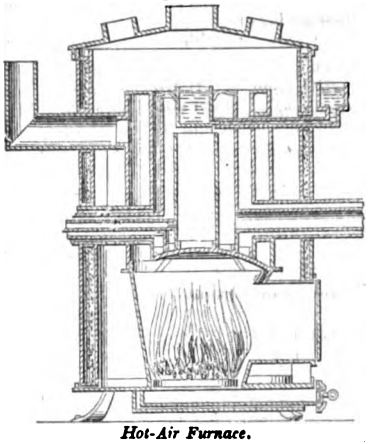


Hot-Air Furnace.

but a common kind is a form of stove in a brick chamber, the air coursing around the stove and among certain pipes and chambers in which circulate the volatile products of combustion. In the example (Fig. 2586) the furnace, with the exception of its face-plate, is inclosed in an air-chamber. The caloric current passes from the furnace *A* around through *D E*, into the auxiliary radiator *G*, down by the V-shaped driving flues *I K L*, and so to the exit. The air circulates around each of the flues in chamber *F*, and against the plates of the furnace.

In Fig. 2587, a series of concentric annular air-flues are placed above the combustion-chamber and communicate with the external atmosphere through

Fig. 2587.



Hot-Air Furnace.

pipes extending into each flue near its bottom. The external jacket of the furnace is filled with coal-ashes. A water-pan above the fire-pot is fed from an external communicating vessel.

Hot-bed Frame. The structure of sides and ends on which the sash of a hot-bed rest.

Hot-blast. A blast of air heated previous to its introduction into the smelting-furnace.

The process was invented by Nielson, of Glasgow, Scotland, and patented in 1828.

In 1845, Budd patented in England the utilization of the heated gases from the blast-furnace for heating the blast. By means of the hot-blast, anthracite coals were used successfully in smelting iron in Wales, in 1837, and at Mauch Chunk, Pennsylvania, in 1838, 1839.

Hot-blast Fur'nace. The temperature of the air, previous to its being thrown upon the charge in the furnace, is raised to about 600° in an outer chamber or in a series of pipes. These are variously arranged.

In that illustrated (*A*, Fig. 2588), the air is first condensed in an exterior chamber, whence it is forced into the pipe *a* within the reverberatory furnace *b*. Branches from this pipe terminate in the tuyeres on each side of the furnace, which has a separate fireplace.

In Staffordshire, the hot-air apparatus is at the mouth of the furnace, and consists of an exterior and interior tube, the former closed and the latter open at each end. The annular space between them is connected by cross-pipes; through these the air is impelled and passes thence to the tuyeres.

Digitized by Google

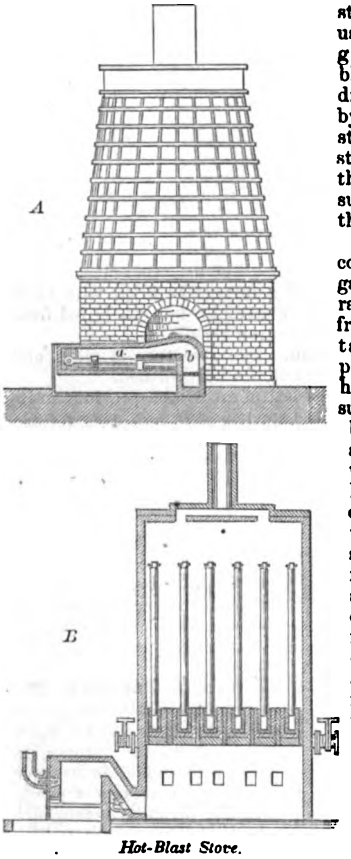
In 1834 M. Dufrenoy reported to the French government the results reached at the Clyde iron-works, which were as follows: —

	1829	1831	1833
For the year . . .			
Temperature of blast .	Cold	450° F.	612° F.
Coal used per ton of iron .	As coke.	As coke.	In raw state.
For fusion, cwt. . .	133	86	40
For heating air, raw coal	nil	5	8
For blowing engines, coal	20	7	11
	153	98	59
Cwt. limestone per ton of iron	10½	9	7

Besides this advantage, the make was increased by more than one third, and a blowing engine, which only supplied three furnaces with cold blast, was equal to four when the air was heated.

Player's stove (*B*, Fig. 2588) for heating furnace-blasts (English) is so constructed as to use the waste gases from blast-furnaces, drawing them by means of a steam-jet into a stove, where they are consumed to heat the air-blast.

Fig. 2588.



Hot-Blast Stove.

The stove consumes the gas in a separate chamber from that containing the pipes to be heated; air to support combustion is allowed to enter, and the heated fumes escape through a series of narrow slots into an air-tight chamber having a damper on the top and containing a series of vertical reverting pipes through which passes the blast to be heated. As the highly heated fumes will not again ignite without a fresh supply of oxygen, the cast-iron blast-pipes remain uninjured under a heat of 1100° or 1200°.

An auxiliary fireplace for burning coal is shown attached to the hot-blast stove. From this fireplace a flue conducts the flame, smoke, and gases from the blast-furnace into the chamber where the combustion is completed. Attached to the end of this fireplace, and connected with flues at the furnace-top, is a branch gas-pipe with a small steam-jet placed near its orifice to create a partial vacuum. This draws the gases down from the furnace-top and forces them into the stoves, where they are burned. The gas-pipe and jet may be placed at the bottom end of the combustion-chamber of the hot-blast stove.

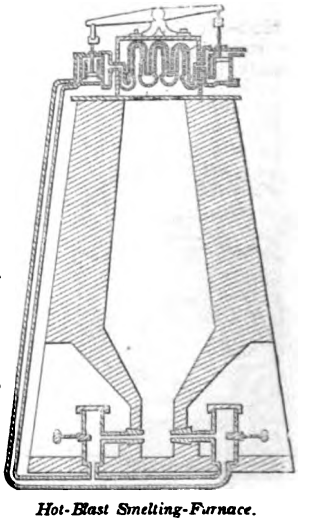
The arrangement of pipes is in six treble rows, each stove contains 18 pipes, 8 inches in diameter by 14 feet high, giving about 1,000 square feet of heating surface. The pipes are disposed three in a row; the blast thus passing up and down three times, discharging into connecting chambers in the roof of the combustion chamber below.

Since 1840, the blast has been gradually made hotter and hotter, and the means of economically and regularly giving the air a temperature of 1,000 or more degrees have attracted much attention.

Cowper's patent is founded on the Siemens regenerative principle, a cellular mass of brick-work being first raised to a high heat, and this heat then imparted to the blast, which is made to pass through it, while a similar mass of brick-work is being heated, ready for use as soon as the first shall have become partially cooled. Whitwell makes his brick-work into large compartments instead of cellular. It is claimed that the blast can be heated to 1800° by this stove, and a regular working heat of 1400° be steadily maintained. To estimate properly the great importance of improved devices for heating the blast, it should be remembered that for every ton of materials charged in at the tunnel-head at least three tons' weight of air is blown in at the bottom through the tuyeres; it can therefore be readily understood how desirable it is that this air should be put into the furnace already heated, instead of throwing the work of heating it upon the fuel in the furnace, which should find abundant employment in smelting the ore only.

In McDowell's apparatus (Fig. 2589), the air-engine and air-pump pistons are connected to opposite ends of a walking-beam; both have double action, and are connected to a serpentine pipe in a chamber at the top of the cupola and communicating therewith. The pump and engine have suitable valves, and communicate respectively with the outer air and the blast-pipe. See also BLOWING-APPARATUS.

Fig. 2589.



Hot-Blast Smelting-Furnace.

Fig. 2590 represents Sturtevant's hot-blast apparatus for drying timber and other materials. In this, air is drawn in by a suction fan, and passed through a series of longitudinal tubes inserted in a cylinder heated by exhaust steam from the engine, whence, at a temperature of 150° to 200°, it is conducted to the drying-room. See LUMBER-DRYER.

Hotch'ing-tub. (*Metallurgy.*) A tub and sieve in which lead ore is agitated in water to separate the metallic and refuse parts. It is preliminary to the *buddle*. See HUTCH.

The *cuttings* are detained by the sieve; the *smeddum* passes through into the bottom of the box.

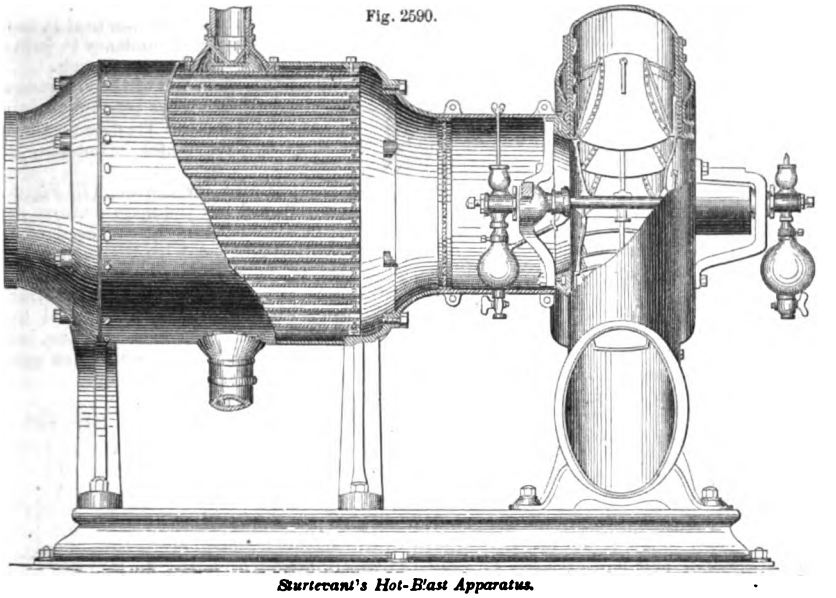
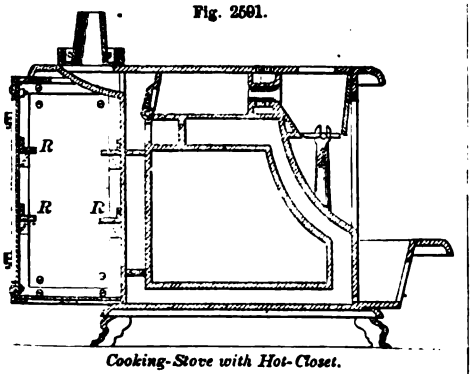
Fig. 2590.



Sturtevant's Hot-Blast Apparatus.

Hot-clos'et. 1. One attached to a stove to keep victuals or plates warm. That shown has ledges *R R* for shelves in the closet.

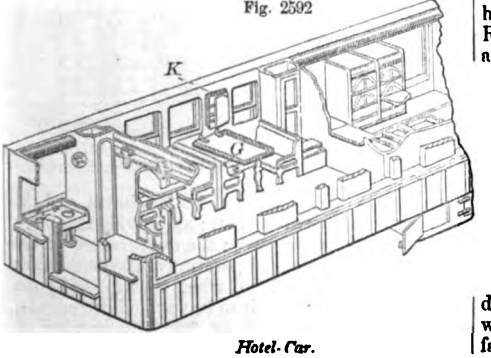
Fig. 2591.



Cooking-Stove with Hot-Closet.

2. (*Candle-making.*) A chamber in which candle-molds are kept at a heat of 150° Fah., previous to pouring, to prevent the chilling of the stearic acid. The steam heat is applied dry.

Fig. 2592



Hotel-Car.

Ho-tel'-car. One arranged for affording meals to passengers on board while on a journey. Closets *K* are arranged between each pair of windows. A water-tank *B* is placed at the upper part of one side, to which also tables *G* are attached, and part of the car is partitioned off as a kitchen, with a cooking-range. A provision chamber *E* is attached beneath the floor of the car.

Hot-flue. A chamber, heated by hot-air pipes, in which printed calicoes are dried.

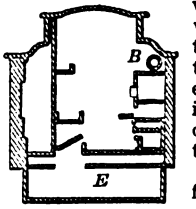
A drying-chamber for cloths or paper, starch, etc.

Hot-gild'ing. A name applied to amalgam gilding, in which the mercury is driven off by heat.

Hot-house. 1. (*Pottery.*) A room where strong heat completes the drying of green ware, previously to placing in seggars and firing in a kiln.

2. (*Horticulture.*) A plant-house where a relatively high artificial temperature is maintained in order to facilitate vegetable growth.

The botanic gardens of Pisa, Padua, and Bologna, established from 1544 to 1568, did not contain hot-houses. In the thirteenth century, however, Albertus Magnus, who was equally active and influential in promoting natural knowledge and the study of the Aristotelian philosophy, possessed a hot-house in the convent of the Dominicans at Cologne. This celebrated man, who had already fallen under the suspicion of sorcery on account of his speaking-machine, entertained the king of the Romans, Wilhelm of Holland, on the 6th of January, 1249, in a large space in the convent garden, where he kept up an agreeable warmth, and preserved fruit-trees and plants in warmth throughout the winter. This entertainment was exaggerated into a tale of wonder in the chronicle Joannis de Beka, written in the fourteenth century.



There is no evidence that forcing-houses were used in ancient horticulture. The conduction of heat by caliducts for baths and apartments was well known, but it does not appear that these facilities were used for floricultural purposes.

Digitized by Google

Regular hot-houses are of late introduction in our botanic gardens. Ripe pineapples were first obtained in Europe at the end of the seventeenth century. Linnæus states that the first banana which flowered in Europe was in Vienna, in the garden of Prince Eugene, in 1731.

The accordant accounts of Hernando Cortes, in his reports to the Emperor Charles V., of Bernal Diaz, Gomara, Oviedo, and Hernandez, leave no doubt that at the time of the conquest of Montezuma's empire, there were in no part of Europe menageries and botanic gardens which could be compared to those of Huaxtepec, Chapultepec, and Tezcuco.

Hot-press. (*Paper.*) A means of calendering and smoothing paper by subjecting it to heavy pressure between glazed boards; a hot iron plate is placed at every 20 sheets or so, to heat the pile.

Hot-saw. A buzz-saw for cutting up hot bar-iron, just from the rolls, into bars or into pieces for being piled, reheated, and rerolled.

Hot-short. (*Metal-working.*) Iron which is disposed to crack or break when worked at a red heat, and is difficult to weld, is said to be hot-short. It is frequently the presence of sulphur to the extent of, say, 0.033 per cent, which makes it brittle.

Hot-shot. Cannon-balls made red hot in a furnace in order to fire wooden structures into which they are thrown.

Hot-wall. A wall with included flues to assist in ripening the fruit of trees trained against it.

In some cases the wall is traversed by a number of flues leading from a furnace or furnaces; in others the entire wall is double, the included space being crossed occasionally by ties which keep the two walls together.

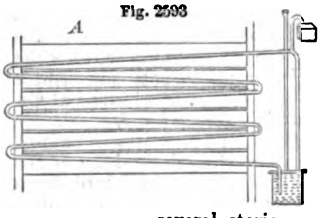
Its use is principally in northern countries in ripening fruits which do not mature in the natural temperature of the latitude, such as the peach, nectarine, and apricot in England.

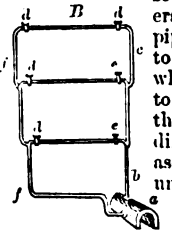
Hot-wa'ter Fau'cet. The faucet of a bath, tank, beck, vat, or wash-basin, which admits the hot water, for scalding, infusing, washing, leaching, or other purpose.

Hot-wa'ter Heat'ing-ap'pa-ra'tus. A means of heating by the passage of hot water through pipes in rooms.

Bonnemain appears to have been the first to introduce the circulation of hot water in a system of pipes, as a means of warming apartments and buildings. He devised it in 1777, in connection with his incubator. See CALORIFÈRE; INCUBATOR. The egg-chamber had several stories, and each was traversed by one or more bends of the pipes, which were so arranged as to have a constant inclination, by which the cooler water descended to the boiler. The velocity of the current depends upon the difference in temperature of the ascending and descending columns.

Fig. 2593





Hood's Heater.

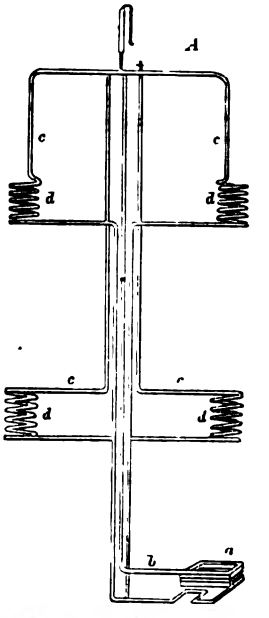
This is shown at *A* (Fig. 2593). Hot-water heating-apparatus on the *low-pressure* system employs a heat at or below the boiling point. By the *high-pressure* system the heat is increased to 350°, and the water has a tendency to form steam of 70 pounds pressure to the square inch.

Bonnemain's system was of the low-pressure kind, and this class of heaters has been much improved by Hood; see his "Practical Treatise on the Warming of Buildings by Hot Water" (London, third edition, 1855).

Hood's apparatus for heating (*B*, Fig. 2593) had several variations, but the main features are similar to those of Bonnemain. It consisted of a boiler *a* and ascending pipe *b c*, with branches to each story, regulated by faucets *d e*. The descending pipes *f* carry back the cooler water. By another system, each story has its own ascending and descending pipes, with separate connection to the boiler. An air-faucet at top is necessary to allow escape of air from the pipes when starting up.

The boiler must be sufficiently strong to bear the hydrostatic pressure of the column of water. A boiler, 3 by 2 and 2 feet deep, with a pipe 28 feet high proceeding from it, will sustain a pressure of 66,816 pounds.

Fig. 2594.

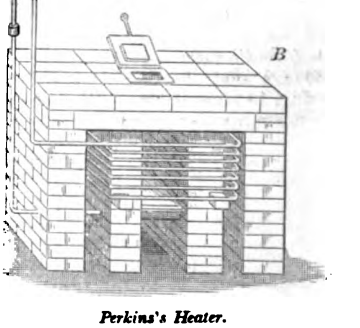


The size of the boiler will depend upon the extent and size of pipe, but one square foot of boiler fire-surface is allowed to every 50 feet of 4-inch pipe, the temperature of which is to be kept 140° above that of the surrounding air.

The quantity of pipe is thus stated in his work above referred to: —

"Allowing 3½ cubic feet of air for each person in the room or hall, as the quantity per minute which is to be warmed, and one cubic foot per minute as the quantity cooled by each square foot of window-glass; then ascertain the whole quantity of air that is to be heated, and apply the following rule:

"Multiply 125 (the excess of temperature of the pipe above the surrounding air) by the difference between the temperature at which the room is to be kept when at its maximum, and the temperature of the external air; and divide this product by the difference between the temperature of the pipes and the proposed temperature of the room; then the quotient thus obtained, when multiplied by the number of cubic feet of air to be warmed per minute, and this product divided by 222 (the number of cubic feet of air raised 1° per minute by 1 foot of 4-



Perkins's Heater.

Digitized by Google

inch pipe), will give the number of feet in length, of pipe 4 inches in diameter, which will produce the desired effect." For 3-inch pipes multiply the said number by 1.33; for 2-inch pipes multiply by 2. The given diameters of the pipes are outside measurement. Small pipes have a relatively larger area of heating surface.

Perkins's high-pressure hot water heating-apparatus (*A B*, Fig. 2594) consisted of a continuous wrought-iron pipe, which formed a coil *a* in the furnace, and passed from story to story of the building, being amplified into coils at special points, as in the apartments to be warmed. The pipe was ½ inch in internal diameter and ¼ inch thick, and about ⅛ of the length of the pipe formed the furnace coil. The heated water in the coil *a* becomes charged with minute globules of steam and ascends in pipe *b*, from whence it is distributed right and left to the apartments by branch pipes *c* and coils *d*. The descending pipes carry the hot water to the story below, where it heats the apartments by means of other coils *d*, which discharge into the descending pipes, by which the water again reaches the furnace coil.

A common arrangement is shown at *B* in the figure; the pipe is coiled around the inner casing of the furnace, coming in contact with the fire only in front; this casing and the top of the furnace are composed of fire-brick, the fire-grate being in the center and elevated a foot or so from the floor; fuel is supplied through a hole in the top. The smoke passes through the chamber containing the pipes, and escapes through a hole in the back.

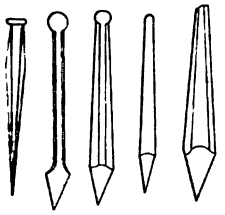
Hot-wa'ter Pipe. (*Steam.*) The pipe which receives the hot water from the hot-well and discharges it.

Hot-wa'ter Pump. (*Steam-engine.*) A pump which raises water from the hot-well of a condensing steam-engine and discharges it into the feed-water cistern, whence it passes in graduated quantities to the boiler. See also FEED-WATER APPARATUS; INJECTOR.

Hot-well. A compartment in the cistern in which the condenser and air-pump of a condensing-engine are submerged, and from which the warm water is drawn for the supply of the boiler.

The submerged *injection-chamber* and the *air-pump* connect by a passage, whose valve opens during the ascent of the piston and closes during its descent. The uncondensed steam, the air, and the water of condensation pass by this passage to the air-pump, through the bucket of the latter as it descends, and are ejected into the *hot-well*. The heated water is drawn thence to supply the boiler. See AIR-PUMP; CORNISH STEAM-ENGINE.

Fig. 2595.



Houguette.

Hou-guette'. The etching-needle of the marble-worker. Fig. 2595 shows several different forms.

Hound'ing. (*Nautical.*) That portion of a mast between the deck and the top of the hounds.

Hounds. 1. (*Vehicle.*) Side bars which strengthen certain portions of the running-gears of a vehicle.

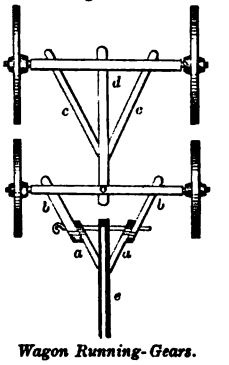
a, tongue-hounds.
b, hounds.
c, hind-hounds.
d, coupling pole or *reach.*
e, tongue.

In wagons, the *hounds* of the fore-axle pass forward and on each side of the tongue, to which they are secured by the tongue-bolt.

The hounds of the hind-axle unite and are fastened to the coupling-pole by the coupling-pin.

2. (*Nautical.*) Projections on the mast-head to support the trestle-trees and top. Cheeks fayed to the sides of the mast-head.

Fig. 2596.



Wagon Running-Gears.

Hour-cir'cle. (*Globes.*) A small brass circle fixed to the north pole, divided into twenty-four hours, and furnished with an index for pointing them out.

Hour-glass. A glass having two bulbs and a connecting opening through which the sand in one bulb runs into the other. The amount of sand and size of the opening are such that a given amount of time is consumed in the passage.

On an ancient bas-relief at Rome an hour-glass is placed in the hands of Morpheus, and Athenæus says that the ancients carried portable hour-glasses with them as measurers of time.

Glasses of this description are yet used for marking small periods of time; such as, —

1. The three-minute glass, or *egg-glass*, in which the sand passes in the time mentioned.

2. The half-minute glass used in ascertaining the rate of a ship by the *log*.

The line is knotted at such intervals that the spaces bear the same relation to a nautical mile that the half-minute does to an hour. That is, they are $\frac{1}{120}$ of a nautical mile apart, — about $50\frac{7}{10}$ feet.

The line being on a reel, the *chip* is thrown overboard, and, catching in the water, causes the line to run off the reel. When the *stray-line* has run out, the half-minute glass is turned, and the number of knots on the string which pass through the seaman's hand indicates the number of nautical miles per hour that the vessel is sailing.

The use of the hour-glass in calculating a ship's course is much older than that of the log, the rate being estimated by the eye. The hour-glasses, *ampolettas*, used in the expedition of Columbus, ran out in half an hour, so that the interval of a day and a night was reckoned at 48 ampolettas, and so the journal — log-book — recorded. The log is not mentioned. It was used in the Pacific by Magellan. See LOG.

The horoscopus in the Egyptian processions carried with him the measurer of time, an hour-glass.

The "Sûrya Siddhânta," a Sanscrit treatise on astronomy, treats of the "stringed sand receptacles" for measuring time; these were doubtless of the general character of our hour-glasses.

Hour-glasses were unknown in China formerly, and of late are mentioned by them as of importation from the West.

A tradition of the Middle Ages relates that the sand-glass (sablier) was invented by Liutprand, a monk of Chartres, who reinvented the art of making glass after the secret had been lost for ages.

Shortly after receiving the famous clepsydra from Haroun al Raschid, Charlemagne caused a monster sablier to be made, which required turning but once in 12 hours. It had the horary divisions marked upon the outside.

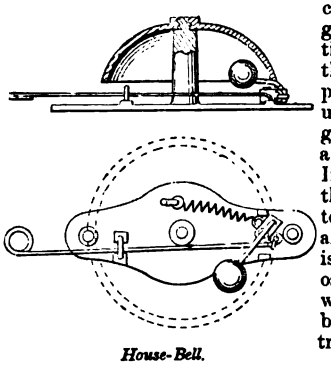
The hour-glass or half-hour glass was a regular part of pulpit furniture in the sixteenth century, to denote to the preacher when it was time to close. It was used in Massachusetts two centuries since for the same purpose.

Digitized by Google

Hour-hand. (*Horology.*) That one which shows the hour on a watch-dial, performing its revolution in 12 hours.

House-bell. A form of bell for doors of houses; formerly a bell suspended by a coiled strip which gave it the repetitive action when the wire was once pulled; now more usually a form of gong which gives a single sound. In the example, the bell is screwed to a central post and the clapper is fastened to an oscillating block which is moved by a rod and retracted by a spring.

Fig. 2597.



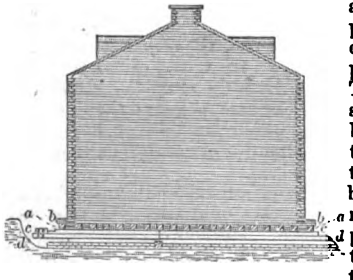
House-Bell.

House-boat. A boat used as a dwelling. Common in China, and once common on our Western rivers.

House-line. (*Nautical.*) Or *housing.* A fine line having three strands, smaller than rope-yarn and used for seizings, fastening thimbles of sails to their ropes, etc.

House-mov'ing. The operation of removing small or moderate-sized frame structures from one locality to another is a task of comparatively easy accomplishment. The house is supported on beams laid in the direction to be taken, beneath which rollers are placed and the power of tackle or of a capstan applied to a rope properly secured to or around the house.

Fig 2598.



House-Moving.

The case of brick buildings, especially those of large dimensions, presents more difficulty.

A foundation is first prepared on the new site. A trench is next cut around the outside of the house, and the earth is also removed from the interior, so as to expose the foundation. Through this, openings are made, into which are inserted, at intervals of about three feet, at right angles to the direction that the house is to be moved, stout beams *a* which project about three feet beyond the walls at each end. Under each of these projecting ends a screw-jack is placed, resting on a firm foundation, and, by the operation of these, the beams *a* are brought up into close contact with the superstructure, the intermediate masonry being removed. Above and resting upon the beams *a* are placed beams *b*, through openings made in the walls for the purpose, and below, transversely to them and in the direction the house is to be moved, two beams *c d* are placed under each end wall; the lower of these has a tongue, and serves as a guide for the upper, which is grooved, and slides upon it. The two surfaces of contact are greased, and a powerful screw-jack, butting against the beams *c*, is fixed horizontally to each of the beams *d*, and operated until the structure is moved the distance which the limit of motion of the screw-jacks allows. They are then unfastened and the operation repeated. By successive additions to the length of the lower beams *d*, this may be continued until the house is moved any required distance.

House-lifting by screw-jacks is now an important business.

This process requires great care and attention, as it is obvious that an inequality in the movement of the numerous screw-jacks tends to crack the walls.

Hous'ing. 1. (*Railway.*) One of the plates or guards on the railway carriage or truck, which form a lateral support for the axle-boxes, and in which they slip up and down as the springs alternately contract and expand. Also called *pedestals, horn-plates, jaws, axle-guards.*

2. The framing holding a journal-box; as, one of the standards holding the journal-boxes of the rolls in a rolling-mill.

3. The uprights supporting the cross-slide of a planer.

4. (*Carpentry.*) The notches in an object for the insertion of another piece; as, —

a. (*Stair-building.*) Notches in the string-boards for the ends of the steps.

b. (*Artillery.*) A prismatic groove in the axletree of a gun-carriage for the cheeks of the transom.

Notches in the *brackets* to fit on the axletree bed, and so on.

5. (*Nautical.*) *a.* That portion of a mast which is included between the keelson and the surface of the upper deck.

b. A covering or protection, as of a ship's deck, when laid up in ordinary or under stress of weather, as in the Arctic regions.

c. A cord made of three small yarns and used for seizings.

6. (*Saddlery.*) *a.* A cloth extending rearwardly from the saddle and covering the loins of the horse.

b. The pad of a collar.

c. A hood or covering piece for the collar.

Hous'ing-bear'ers. (*Metal-working.*) The frame in which the rollers of an iron-rolling mill are set. *Housing-frames.*

Hov'el. (*Porcelain.*) A conoidal structure of brick, 40 feet in diameter and 35 feet high, around which the *ovens* or firing-kilns are clustered.

How'el. (*Coopering.*) A plane with a convex sole, used for smoothing the insides of barrels and casks, making the smooth circle at the croze, and also the chamfer on the inside of the chine.

How'it-zer. A cannon, differing from ordinary guns in being shorter and lighter in proportion to its bore, and used for throwing hollow projectiles with comparatively small charges. A 6-pdr. gun weighs 100 pounds more than a 12-pdr. howitzer. Their charge of powder for a 12-pdr. field howitzer is ¾ pound of powder; that for a 12-pdr. mountain howitzer is ½ pound of powder. A smaller chamber at the bottom of the bore receives the powder.

a, mountain-howitzer.

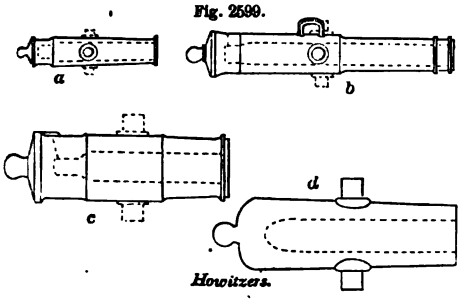
b, field-howitzer.

c, siege-howitzer, model of 1850.

d, the siege-howitzer, 1861, has a chamber the size of the bore. See MOUNTAIN-HOWITZER.

Digitized by Google

Fig. 2599.



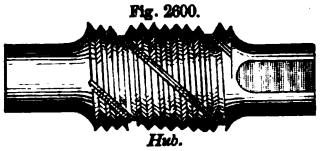
Howitzers.

How'ker. (*Vessel.*) A Dutch vessel with two masts. The *hooker* is an Irish fishing-smack.

Hoy. (*Vessel.*) A one-masted coasting-vessel, used before the era of steamboats for conveying passengers and goods between places, or as a tender upon larger vessels in port.

Hub. 1. A fluted screw of hardened steel, adapted to be placed on a mandrel between the centers of a lathe, notched to present cutting-edges, and to be used in cutting screw-tools, chasing-tools, etc. The chasing-tool, for instance, is laid on the rest and pressed forcibly against the *hub*. (Fig. 2600.)

Fig. 2600.



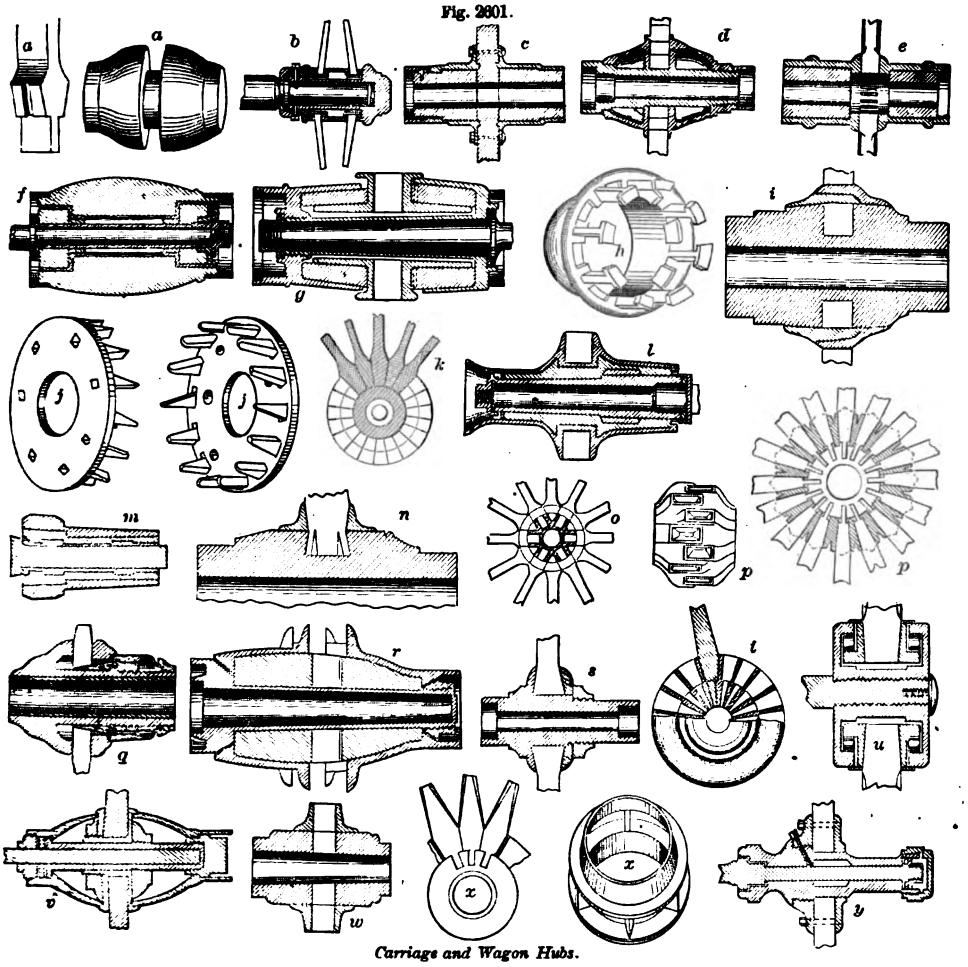
Hub.

2. (*Die-sinking.*) A cylindrical piece of steel on which the design for a coin is engraved in relief. The engraving is done while the steel is soft, and, after hardening, the *hub* is used to make *matrixes*, from which are made *punches* which impress the *dies* used in *coining*. (See MATRIX; PUNCH; DIE.) The *hub* or the *punch* is pressed upon the softened steel *blank* in a powerful screw-press; and the *matrix* or *die* is removed, annealed, and replaced several times, as the pressure has the effect of hardening.

3. (*Vehicles.*) The central portion of a wheel which is slipped upon the *arm* of the axle, and in which the spokes are set radially. The *nave*.

A bronze hub, with peripheral sockets for the reception of the spokes, is in an ancient Scythian chariot, found in Egypt, and now in a European museum, probably that of Berlin. It is supposed to have been carried to Egypt as a trophy by a conqueror of that nation. See CHARIOT.

Fig. 2601.



Carriage and Wagon Hubs.

Digitized by Google

a is a hub having a circumferential groove, in which the shoulders form a continuous band, while the tenons of the spokes set in mortises in the bottom of the groove.

b is a metallic hub, one portion of which forms the axle-box around which are the nuts on the inner ends of the double set of iron spokes.

c has two circumferential metallic bands, between which the spokes, forming a solid circular series, are clamped and bolted; the clamps also holding the wooden sleeves around the axle-box.

d. Around the hollow axle-box are clamped two hollow disks, which have projecting lugs to form the spoke mortises.

e has a metallic shell having a depressed center, in which the spoke mortises are formed, and has tubular cases driven in from the ends.

f has rubber disks around the axle-box at each end of the hub.

g has a central disk forming the spoke-sockets, and this is clamped by two outer disks with intervening hollow cones.

h has two hollow shells with T-shaped lugs, which interlock to form spoke-sockets.

i has two overlapping mortised hub-bands.

j has two metallic disks, with projecting lugs to form spoke-mortises; the disks are drawn together with bolts.

k has a grooved hub with alternate projecting lugs to form dodging mortises.

l has a soft metal or plastic material run in between the axle-box and the shell of the hub.

m resembles the previous in some respects.

n. The hub has a dovetail mortise and wedges to prevent the withdrawal of the spokes, and beveled metallic bands to form seats for the spokes.

o has a mortised hub and metallic bands to clamp the spokes, which form an arch around the hub.

p has a hub-band with staggering metallic sockets, and hub with mortises for the spoke-tenons.

q has wedges against the inner ends of the spokes; these are driven outward by the inner hub-band, which screws on the sleeve of the outer portion of the hub-band.

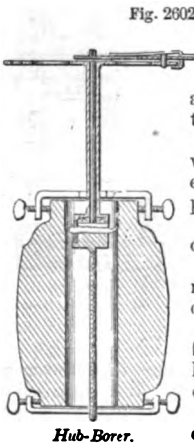
r has a metallic shell with staggering mortises and projecting lips to support the spokes.

s has a metallic hub formed in three parts, — the axle-box and inner hub-band, the outer hub-band, and the clamping-nut. The circular spoke-groove has a dovetail form.

t has a metallic band with beveled mortise.

u. The end flanges are screwed on the axle-arm. The inner ends of the spokes are secured in a mortised flange-ring, between which and the hub-flanges are anti-friction rollers.

Fig. 2602.



Hub-Borer.

v has a metallic hub-shell within which is a spoke-socket formed by sleeve, nut, and projecting lips.

w, a mortised metallic band on a wooden hub.

x has a metallic band whose mortises receive the spokes in clusters.

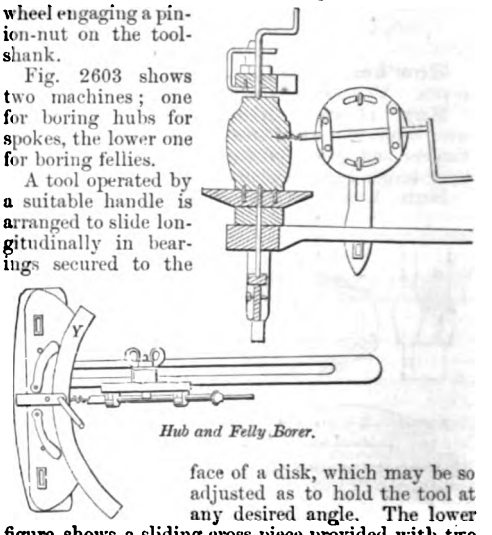
y has a metallic hub which forms the axle-box, and has a lubricating-chamber and spoke-clamps.

4. A block for scotching a carriage or car wheel.

Hub'ble-bub'ble. An onomatopoetic word. A pipe in which the smoke is drawn through water.

Hub-bor'er. (*Wheelwrighting.*) An implement or machine for boring hubs for the boxing or the spokes. That in Fig. 2602 is for the former purpose. Clamps at each end of the hub form guides for the central shaft, which has a box to carry the cutter, whose progression is obtained by the thread on the shaft. The cutter has a threaded shank, and is fed outward to enlarge the diameter of the bore by the rotation of the tube, which has a crown-wheel engaging a pinion-nut on the tool-shank.

Fig. 2603.



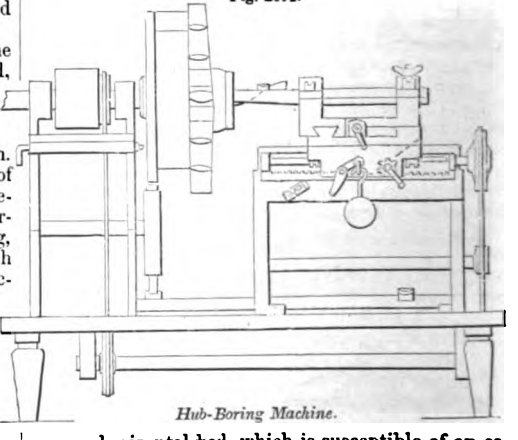
Hub and Felly Borer.

Fig. 2603 shows two machines; one for boring hubs for spokes, the lower one for boring fellies.

A tool operated by a suitable handle is arranged to slide longitudinally in bearings secured to the face of a disk, which may be so adjusted as to hold the tool at any desired angle. The lower figure shows a sliding cross-piece provided with two arms which are adjusted to hold the felly *Y* in position while being bored by a set screw having a handle.

Hub-bor'ing Ma-chine'. The machine (Fig. 2604) bores the hub by the rotation of the latter rather than of the former. The boring-tool is mounted upon a horizontal bed, which is susceptible of an oscillating motion about a center for the purpose of allowing the tool to be set at any desired angle. With this bed is combined a laterally adjustable tool-holder and a longitudinally adjustable carriage. The carriage is provided with a contrivance for throwing it in and out of gear, with a feeding-screw for the purpose of feeding the tool up to its work with a slow motion, and retracting with a quicker motion.

Fig. 2604.



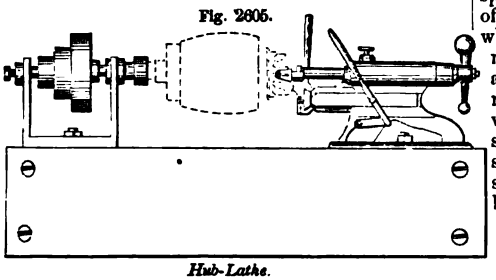
Hub-Boring Machine.

Digitized by Google

Hub-cen'ter-ing Ma-chine'. (*Wheel-making.*) A machine in which a hub is chucked while the hole for the axle-box is reamed out concentric with the outside shape. A similar mode is adopted for holding the hub while setting the boxes therein.

Hub-lathe. (*Wheelwrighting.*) A form of lathe for turning carriage and wagon hubs. In the example, the cutter is held and fed to its work by a double slide, and its lateral movement is regulated by the adjustable stop attached to the cross-head of the double slide.

Fig. 2605.



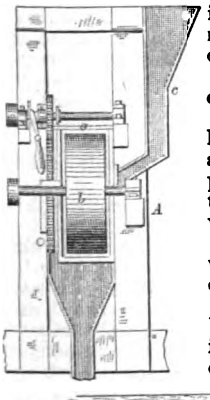
Hub-Lathe.

Hub-mor'tis-ing Ma-chine'. (*Wheelwrighting.*) A machine in which a wheel-hub is held upon a mandrel or stake, so disposed that a reciprocating chisel may cut therein the mortises for the spokes. The hub is dogged or clamped so as to prevent rotation while the mortise is being cut, and is then rotated a determinate number of degrees to present the next spot to the cutting-tool.

Hub-turn'ing Ma-chine'. (*Wheelwrighting.*) A form of lathe specially adapted for turning hubs for vehicle wheels.

Huck-a-back. (*Fabric.*) A table linen or toweling having the weft alternately crossed, so as to make it thick at certain points to roughen the surface by producing a raised pattern.

Fig. 2606.



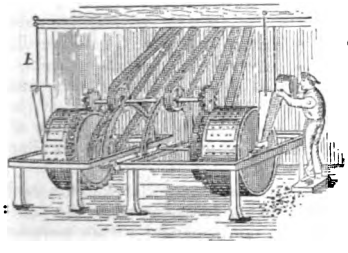
Huf'fing. A process of ornamenting gilded leather.

Hulk. (*Nautical.*) The hull of a vessel not seaworthy, and moored in port for hospital, guard, convict, quarantine, custom-house, storage, victualing, or other purposes.

A *sheer*-hulk is one fitted with *sheers* for masting and dismasting vessels.

Hull. (*Shipbuilding.*) The body of a vessel, exclusive of its masting, rigging, etc. A dismantled *hull* is a *hulk*.

Hull'er. See HULLING-MACHINE.

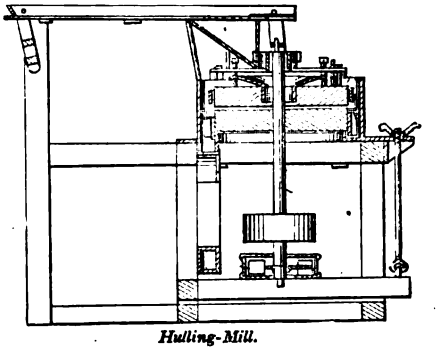


Barley-Huller.

Hull'ing-ma-chine'. (*Agriculture.*) A device for removing the cuticle from grain, and for breaking it without reducing it to the condition of meal. In the time of Pliny a mortar was employed for this purpose, sand or pieces of brick being placed therein to assist the trituration. Foreign substances, including the husk and bran, were removed by sifting. For this purpose, the Egyptians used sifters made of papyrus and rushes, the ancient Spaniards of flax, and the Gauls invented sieves of horsehair.

The Scotch pearl-barley mill is shown in Fig. 2606, *A* being a section of the cylinder, and *B* a perspective of the machines in operation. It consists of a drum *a*, which is rotated by gearing, and within which a circular grindstone *b* is caused to revolve more rapidly by belting. The grain is fed through a hopper *c* opening axially into the drum, and is removed by a sluice at its side. The drum is lined with sheet-iron, perforated with small holes, which serve to remove the skin and a portion of the outer substance of the grain, bringing it to a spheroidal shape; whence the name of *pearl* barley. *Pot* barley has merely the outer skin removed.

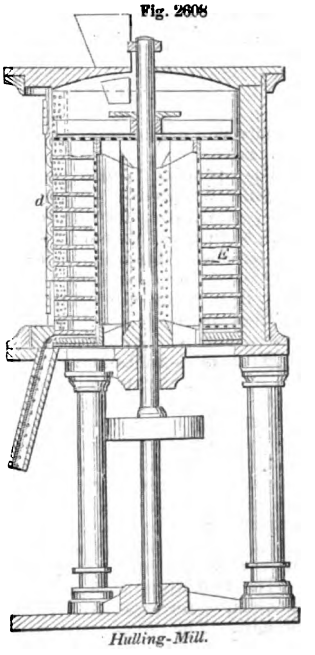
Fig. 2607.



Hulling-Mill.

Fig. 2607 illustrates a machine in which the hulling process is effected between two horizontal stones adjustable relatively to each other, so as to give the requisite trituration without pulverizing the grain.

Fig. 2608



Hulling-Mill.

The machine shown in Fig. 2608 has a revolving wire-gauze cylinder, provided with rough-surfaced shelves *E E*, on to which the grain is successively conducted by conduits *d*, in its downward passage from the hopper. An internal fan eliminates the husk, etc., during the process.

There are some other varieties of machines which depend partly upon percussion, an example of which has a series of the ordinary triangular saw-files projecting radially from an axis rotating at high speed within a cylindrical casing. See HOMINY-MACHINE.

Hum'bug. (*Menage.*) A nippers for grasping the cartilage of the nose. Used with bulls and other refractory bovines.

Hum'hum. (*Fabric.*) A plain, coarse, cotton cloth, made in India.

Hum'mel-ing-ma-chine'. A machine for breaking off the awns of barley. It consists of a vertical shaft provided with several beaters at several different levels and revolving

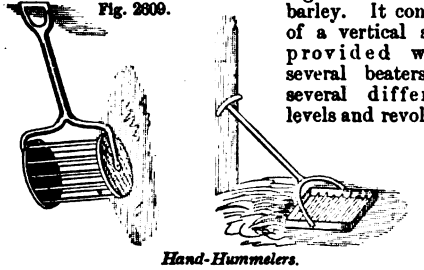

Fig. 2609.

Hand-Hummelers.

rapidly in a cylindrical case so as to beat the grain as it falls.

The operation is also performed in a thrashing-machine by putting the grain through a second time, substituting for the ordinary cover a tin case with teeth made by punching holes through it from the outside. Hand-hummelers or *aveling-machines* (Fig. 2609) are used upon the grain spread on the barn floor, being either rolled or dragged.

The Japanese hummel their rice in a mortar made of a section of a large tree hollowed out.

Hun-ga'ri-an Leath'er. (*Leather.*) A white leather originally made in and imported from Hungary, but now manufactured in other countries.

Mineral salts are substituted for vegetable extracts. The hides are first treated with a mixture of alum and common salt, by which a portion of the sulphate is converted into the chloride of aluminium. An excess of salt keeps the hides supple. The fleshing and scraping processes are proceeded with as in the ordinary modes of tanning, but the hair is removed by shearing instead of liming.

The first alum bath has, alum 7 pounds, salt 4½ pounds, water 8 gallons, for each hide of 85 pounds weight. The temperature is raised to 120° F., and the sides are extended in the bath, hair side up. They are tramped while in the bath; this is three times repeated in warm liquor, the strength of the liquor being maintained. The skins then lie 8 days in the menstruum.

The skins are taken out, stretched, and shaken, and then treated by a saline bath as before, but only lying 24 hours in the liquor at the conclusion of the repeated tramping processes. The hides are then drained, partially dried, stretched, suspended by their edges, and exsiccated. See TAWING.

The skins are tramped and rolled till rendered supple, and are then ready for the oiling process.

The oiling material is a mixture of tallow and fish-oil, the ordinary *dubbing* of the American currier; this is spread by a mop on the flesh and the hair sides of the skins, which are made into a pile flesh side up.

An open charcoal fire is then lighted in the room, which is closed air tight, and after an interval, and the opening of the door for the escape of carbonic acid, the workmen enter, and grasping a skin by the ends hold it, flesh side down, over the charcoal fire, at the same time stretching it in all directions. As each side is *flamed*, it is laid on a table, the pile of warm and greasy hides being covered with a cloth and left to mellow, absorbing the oil and equalizing the heat throughout the mass.

The hides are then wiped of superfluous grease; laid across poles, flesh side out; dried, weighed, stamped, and marketed. The result is said to be excellent, no acid, alkali, fermentative, or other destructive application or process detracting from the weight or injuring the cohesion of the tissues.

Hun-ga'ri-an Ma-chine'. (*Hydraulic Engineering.*) The Chemnitz pressure engine. See AIR AS A WATER ELEVATOR, Fig. 58.

Hunt'er's Screw. A differential screw; named after its inventor, Dr. John Hunter. See DIFFERENTIAL SCREW.

Hunt'ing-cog. (*Gearing.*) A tooth in a cog-wheel which is *one* more than a number divisible by the number in the pinion with which it engages. If the pinion contains 8 leaves and the wheel 65 teeth, the 65th, or *hunting-cog*, prevents the recurrence of each leaf of the pinion with every 8th cog of the wheel, which would be the effect were the relative numbers 8 and 64. When the numbers are 8 and 65, the wheel will revolve 8 times and the pinion 65 times before the same leaves and teeth will be again engaged.

Hunt'ing-horn. (*Music.*) *a.* A bugle used in the chase.

b. A wind-instrument of metal, usually with a circular tube. See HORN, *k.*

Hunt'ing-watch. (*Horology.*) A watch with a metallic case over the crystal for its protection.

Hur'dle. 1. (*Husbandry.*) A rectangular frame of vertical stakes and interwoven withes of hazel, elm, oak, or other suitable saplings. Hurdles, about 6 feet long and 3 feet high, are used in husbandry in making temporary enclosures and fences, each section being secured by a ring to a driven stake.

Ornamental hurdles for screens, fences, etc., are made of iron, either cast or wrought. Each hurdle forms a panel, and is secured at its ends to stakes. Cast-iron hurdles consist of the marginal frame and an ornamental filling, according to the taste of the designer. Wrought-iron hurdles have a frame of bar-iron, and interlacing work of wire resembling network.

2. In *fortification*, hurdles are smaller, and are used as *revetments* in embrasures to strengthen the parapet. The *gabion* commonly used for this purpose is a *crate*, differing from a hurdle only in being cylindrical. See GABION.

A rectangular, flat structure made of stakes and withes, used in an emergency to stop breaches.

Digitized by Google

3. (*Hat-making.*) A grid of wood or wire, on which a bunch of felting hair is laid for *bowing*.

Hur'dle-nail. A tough flat-headed nail used in securing the parts of a hurdle together.

Hur'dy-gur'dy. (*Music.*) A stringed instrument having a lute-shaped body and neck. The strings are regulated on the latter by the fingers, and are vibrated by a revolving wheel.

Hurl. (*Hatting.*) The table on which the material for a hat-body or the fur for a nap is *bowed*.

Hur'ri-cane-deck. (*Shipbuilding.*) 1. The upper deck of an American river or lake steamboat above the cabins.

2. A raised platform on an ocean-going steam-vessel, extending from side to side, above deck amidships. A station for the officer in command.

Hur'ries. A *staith* or timber framing, on to which coal-cars are run, and from which they discharge their loads by means of spouts to the holds of the ships.

Hurst. The ring or collar of a trip-hammer helve on which are the trunnions on which it oscillates.

Hur'ter. 1. (*Fortification.*) *a.* A timber placed at the foot of the interior slope as a revetment, to prevent the injury of the parapet by the wheels of the gun.

b. (*Of a gun-carriage.*) Pieces of wood or iron at the front of the chassis to prevent the top carriage from running off when "in battery." The counter-hurter is a similar piece at the rear of the chassis for checking the recoil of the carriage.

2. (*Vehicles.*) A butting-piece on an axle. A strengthening piece placed against a shoulder of an axle.

Hus'band-ry. For list of machines, implements, and tools, see AGRICULTURAL IMPLEMENTS and HUSBANDRY, pp. 23–25.

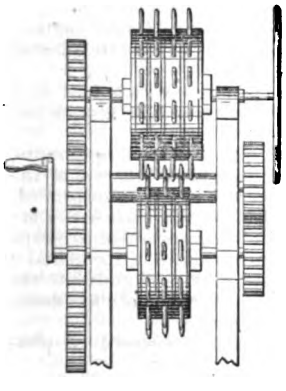
Hush'ing. (*Mining.*) *a.* A term applied to one mode of exposing and collecting ore. In a ravine where surface ore is exposed or but lightly covered, a body of water is dammed and then allowed to *flash* through the ravine, tearing up the earth and stones and exposing new surfaces, from whence the ore is gathered. The word is probably a corruption from *flushing*, which signifies a copious dash of water, as *flushing a sewer*. See FLUSHING.

b. A process of clearing water from the surface of ore, in stream works, by diverting and directing streams of water thereon.

Husk. (*Milling.*) The supporting frame of a run of millstones.

Husk'er. An implement or a machine for removing the shucks from ears of corn. See CORN-HUSKER.

Fig. 2610.



Husk-Hackler.

Husk-hack'ler. A machine for tearing corn-husks into shreds for stuffing for mattresses, pillows, cushions, etc.

Fig. 2610 shows a hackling-machine in which the toothed cylinders are driven at different rates of speed, whereby a splitting and combing action is obtained, as the husks are fed through.

Husk'ing-glove. A glove with claws or prongs, adapted to grasp the ear of corn and tear the husk therefrom. Some of these implements have also cutting jaws to sever the butt of the ear from the stalk.

Husk'ing-peg. A pin or claw worn upon the hand and used to assist in tearing open the shuck when husking ear corn. Ingenuity is apparently exhausted in contriving convenient rings and rests for the fingers, and mode of attaching to the hand.

Hut. The back end or body of the breech-pin of a musket.

Hutch. 1. (*Mining.*) *a.* A low-wheeled car adapted to run on a track in the gallery of a mine, to be lifted on the cage to the surface, and then run off to the dumping chute, by which its contents are carried to wagons.

b. A cistern or box for washing ores.

2. (*Milling.*) The case of a flour bolt. A *bolting-hutch*.

3. A kneading-trough.

Hutch'ing. (*Mining.*) A separation of ore in a sieve, which is suspended from a lever or held in the hands, and agitated in a vat of water. See JIGGER.

Huy-ghen'i-an Eye-piece. (*Optics.*) The *negative eye-piece*, named after its distinguished inventor, Christian Huyghens, a Dutch astronomer (1629–1695). This wonderful man excelled in mathematical and mechanical science and art. He improved the telescope; discovered the ring of Saturn (as such); reapplied the pendulum to beating time, and first accurately adapted it; invented the micrometer; and in his various communications to the Academy of Sciences in Paris and the Royal Society of London illuminated all he undertook.

He was one of the emigrants driven from France at the revocation of the Edict of Nantes, and exchanged the friendship of Louis XIV. for that of Newton. See NEGATIVE EYE-PIECE.

Hy-al'o-graph. An instrument for tracing a design on a transparent surface.

Hy-al'o-type. (*Photography.*) A photographic positive on glass.

Hy'drant. A valve and

Fig. 2611.

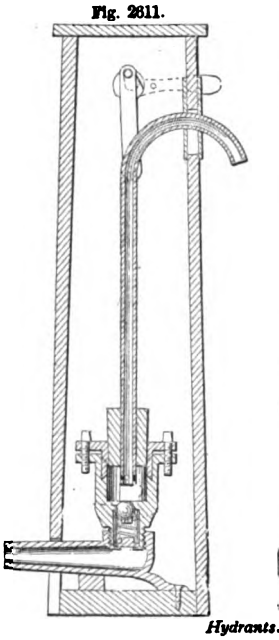


Fig. 2612.

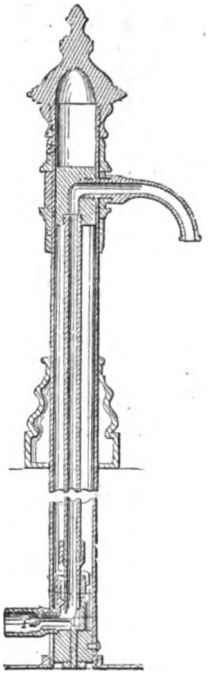


Hydrants.

Digitized by Google

spout connecting with a water-main, and by which water may be drawn from the latter. In the domestic form, as usual in the yards of our city houses, the spout is elevated sufficiently to allow it to discharge into a tub or bucket, the valve being operated by a handle. Provision is also made for allowing the contents of the discharge-pipe to run back out of the way of frost. In the example, Fig. 2611, the depression of the goose-neck forces a piston into a chamber which empties itself through the discharge-pipe; the end of the pipe depresses a valve and allows the water to flow continuously from the main. The elevation of the goose-neck closes the valve, and the rising of the piston empties the discharge-pipe into the piston-chamber.

In Fig. 2612, the water is let on or off by rotating the tube, which opens or closes the foot-valve *I* by means of a stud on the tube. Near the lower end of the tube is a perforation which may be brought into coincidence with a wasteway when the valve is closed, and thus empty the stand-pipe.

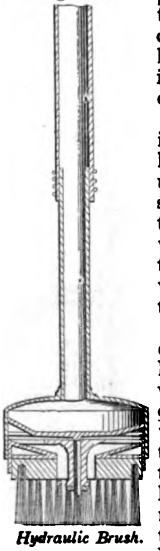
A large kind of hydrant, having a larger service-pipe from the main, and used for connection of hose for street washing or in case of fire, is known as a *fire-plug*.

Hy'dra-pult. A garden syringe. A force-pump on a portable scale.

Hy-drau'lic Belt. An endless woolen band for raising water. The lower bight is immersed in water, and the upper bight passes over a roller. The belt travels about 1,000 feet per minute, and discharges at its upper turn.

Hy-drau'lic Block. (*Shipbuilding.*) An hydraulic lifting-press occupying the place of a *building-block* beneath the keel of a vessel in a repairing-dock. Being adjustable as to hight, it is useful for straightening a ship that has become *hogged* or *sagged*.

Fig. 2613.



Hydraulic Brush.

Hy-drau'lic Brush. One having a hose connection through its handle so as to discharge water upon the surface or object being scrubbed. The one shown, intended for washing windows, has vanes in the stock, and the force of the water causes the brush to revolve and the water to spray upon the window.

Hy-drau'lic Cane. This pump consists of a vertical pipe whose lower end has a valve opening upwardly and plunged in the water of the cistern or well. A rapid vertical reciprocation is given to the tube, and the water is caused to ascend therein; positively as the lower end plunges into the water raising the valve, and relatively as the water slips in the tube as the latter descends quickly. An air-chamber above makes the discharge continuous.

Hy-drau'lic Ce-ment'. A cement which possesses the property of hardening under water and resisting decomposition by that element. Various substances, mixed with sand, have been employed for this purpose, fulfilling more or less perfectly the required conditions.

Septaria are used where readily procurable.

The Romans used pozzuolana, volcanic ashes containing a considerable proportion of clay and oxide of iron. A similar product called *trass*, found in large quantities on the Lower Rhine, is used in Germany. For lining their reservoirs, the Romans employed pure lime and finely pounded brick.

The principal supply is, however, derived from various limestones which contain insoluble matters, as silica, alumina, magnesia, and oxide of iron, in varying proportions. These are burned, causing chemical changes and combinations in the constituents of the mass, which is then pulverized for use.

The so-called "Roman" cement, patented in England by Parker in 1796, is prepared from nodular concretions of limestone, usually containing veins of calc spar, found in beds of clay.

Portland cement, which ranks among the highest in point of tenacity and durability, is made from the deposits formed in the beds of some rivers which flow through chalk and clay formations, mixed with a proportion of carbonate of lime. These are incorporated under water, burned, and ground.

Several varieties of hydraulic cement are prepared in the United States, where it is also very generally known as "water lime." See CEMENT.

Hy-drau'lic Clock. An ancient form of time measurer. It was described by Ctesibus. One was presented by Haroun al Raschid to Charlemagne about A. D. 801. See CLEPSYDRA.

Hy-drau'lic Con-dens'er. (*Gas.*) The chamber into which gas from the retorts is conveyed by the dip-pipes to be cooled. See HYDRAULIC MAIN.

Hy-drau'lic Crane. (*Hoisting.*) An application of the hydraulic press to lifting. See HYDRAULIC ELEVATOR, HOIST, LIFT, etc.

Hy-drau'lic Dock. An apparatus (*J*, plate opposite page 1150) by which a vessel is raised clear of the water for examination and repairs. The vessel is brought over a platform which is slung between the frames, being suspended by the requisite number of chains, say 20 on each side, which pass over cast-iron pulleys supported on the top of the wooden framework. The lower ends of the chains are fixed to the platform, and the upper ends to a horizontal beam of wood, which is attached by means of a cross-head to the ram of an hydraulic engine. When the ram, therefore, which is placed in a horizontal position, is moved, by the injection of water into the cast-iron cylinder in which it works, the motion is communicated to the horizontal beam, and thence, by the suspending chains, to the platform bearing the vessel, which is thus slowly raised to the surface.

The longitudinal and the end view of the platform and vessel will explain the operation of the apparatus. In both of these views, *a* represents the platform; *b*, the suspending chains; *c*, the pulleys on which they run; *d*, the horizontal beam to which the chains are attached; *e*, the hydraulic engine; and *f*, the injection-pipe by which the water is forced into the ram.

The fixtures of the cylinder are embedded in a large mass of masonry, so as to render it quite immovable.

There are several racks attached to the apparatus, for supporting the platform, and taking part of the weight off the ram after the vessel is suspended. When she is ready to be lowered, these racks are unshipped, and the water being permitted to escape through a small aperture provided in the cylinder for that purpose, the vessel slowly descends into the water. The perpendicular *lift* of one of these docks in New York Harbor is ten feet.

Hy-drau'lic El'e-va'tor. (*Hoisting.*) A platform lift worked by hydraulic power.

A strong rectangular frame having a hydraulic press at each corner. These are operated by a larger

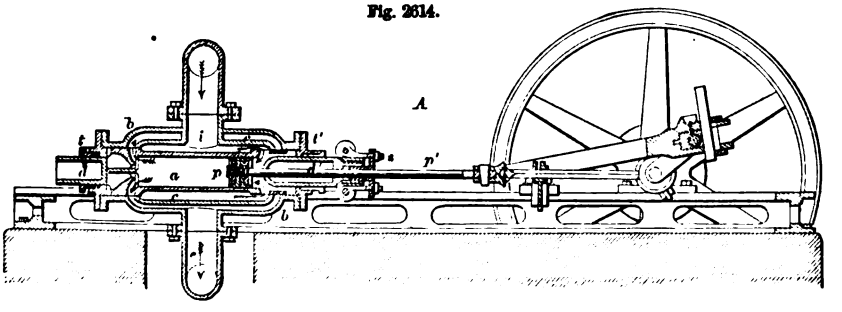
Digitized by Google

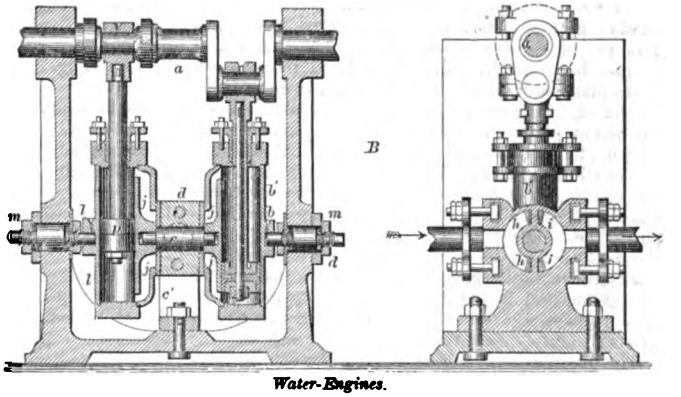
and a smaller pump. On the plungers of the pumps rest two additional frames, arranged to have a truly vertical motion. The machine is adapted for transferring railway-carriages from one line of track to another, and for this purpose is placed under the carriage, and the larger pump worked until the frames are brought to bear under the axles; the operation of the smaller pump then lifts the flanges of the wheels clear of the rails. When the carriage is transferred, the water is allowed to flow back from the pumps to the cistern, and the carriage lowered into place on the rails. See also Figs. *J*, plate opposite page 1150, and *L*, page 1157.

In 1812, Bramah patented a plan for laying water-mains in cities, the water to be under heavy pressure from force-pumps, and to be used for extinguishing fires and for operating hydraulic machines in factories, warehouses, etc., for elevating heavy weights, goods, etc.

The Ascenseur Edoux of Paris consists of a cylinder 66 feet long, sunken perpendicularly into the earth, with a plunger descending into it to the same depth, and packed water-tight at the top of the cylinder. Into this, below the packing, water is admitted by means of a valve. The piston rises under the pressure of the water to the required hight. The descent was effected by allowing the water to escape. See WATER-ENGINE.

Fig. 2614.





Water-Engines.

Hy-drau'lic En'gine. 1. An engine or machine employed in raising water, as pumps, etc.; or receiving motion by the weight or impulse of water, as water-wheels, etc.; or in transmitting power, as the hydrostatic press, etc. See HYDRAULIC ENGINEERING AND APPLIANCES; PUMP; WATER-ELEVATOR; WATER-WHEELS, etc.

2. A machine driven by the pressure of a column of water; the term is especially applied to one in which the piston of a cylinder is driven by water-power.

The hydraulic engine of Huelgoat, in Brittany, is used to drain a mine; is single-acting, and acts directly to lift the piston of the pump. It makes five and a half strokes per minute, the stroke being a little more than eight feet in length. The piston-rod is 767 feet long, and it weighs 16 tons. The power of the engine is derived from a source at a hight 370 feet above its own level. See Delaunay's "Mechanics."

Perret's hydraulic engine *A* (French) has a cylinder and a double-acting piston. The motion is communicated to a working shaft in the ordinary way. The peculiarities consist in the manner of admitting and discharging the water. This is effected through openings at each end of the cylinder which occupy the greater part of its circumference and form a sort of annulus; there being left only enough solid metal to connect the end of the cylinder with the body. Thus the water is admitted to the interior from all sides. To facilitate this, the cylinder is entirely enveloped by a second cylinder, with a space intervening between the two, which is filled with the water of induction. The extreme portions of the working cylinder are turned very smooth externally in a lathe, and the ends of the enveloping cylinder are here contracted, and turned likewise on the inside, so as to make a joint as nearly as possible water-tight. Both these cylinders are enveloped completely by a third and larger one, between which and the second there is a space for the escape of the water on its discharge. This cylinder and the second are cast in a single piece, and form one body. The extremities of the third, like those of the second, are adapted accurately to the surface of the first, but there is a space between the second and third at this surface, which is as wide as the annular series of openings above described in the first, by which the water is to be admitted into or discharged from the first, which is the working cylinder. The inner cylinder moves backward and forward alternately, so as to present the openings which answer to its valves in front of the spaces which communicate with the supply and exhaust.

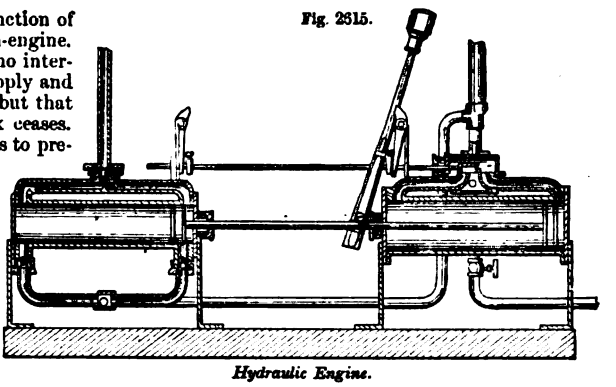
The motion of the working cylinder through the small space which is required to effect the admission and discharge of the water is accomplished by means of an eccentric upon the crank shaft, which is set at right angles to the crank, and 90° behind it in the direction of revolution; so that the motion of the cylinder is in a direction contrary to that of the piston in the first half, and in the same direction in the last half, of the stroke. The breadth of the annular opening is exactly equal to that of the metal which separates the supply from the exhaust in the exterior cylinders; and it will be seen that the

Digitized by Google

working cylinder itself performs the function of the slider in the valve-box of the steam-engine. It happens accordingly that there is no interval between the shutting off of the supply and the commencement of the discharge; but that the efflux begins the moment the influx ceases. The main object of the specific devices is to prevent jar.

a is the inner cylinder.
b the external cylinder.
c the intermediate cylinder.
p is the piston beginning to advance.
i is the induction, *e* the eduction pipe.
d d' are prolongations of the working-cylinder, of smaller diameter, sliding back and forth in stuffing-boxes *t t'*.
p' is the piston-rod working in a stuffing-box *s*.

Fig. 2615.



Hydraulic Engine.

In Coque's water-engine a small quantity of air is admitted along with the water, to absorb hydraulic concussion.

Ramsbottom's hydraulic engine *B* (English) is oscillating, and employs two cylinders *b' l*, operating one crank-shaft *a*, by means of two cranks at right angles to each other. In one of the accompanying figures the channels of induction are marked *j*, and are cast with the cylinders; the dotted circle *c* shows the position of the supply and discharge pipes; in the other figure these pipes are indicated by arrows. The two views are vertical cross-sections at right angles to each other, one being through the axes of the cylinders and the other through the middle post in which the inner trunnions of the cylinders are journaled. The apertures of induction are seen at *h* and those of eduction at *i*, and have the form of truncated circular sectors, whose center is the center of motion. The induction and eduction spaces are divided by a sectoral partition; the apertures of admission and discharge on the sides of the cylinders are of similar construction. The surfaces of contact between the cylinders *b' l* and the support *d* are plane and polished, and are made water-tight by the adjusting screws *m m* of the pivots. When the piston *p* is at the end of its course in either direction the cylinder and crank are vertical, and the valves all momentarily closed, the openings by which the channels *j j* communicate with the discharge and supply pipes presenting themselves exactly opposite the solid sectors which separate *h* from *i*. In the next moment the flow of water will recommence, the cylinder discharging itself from the full side of the piston, and filling anew from the opposite side. Air-chambers and relief-valves are used as a provision against counter-pressure and hydraulic shocks.

The Ramsbottom engine is largely used in England for operating printing-presses, circular saws, lathes, cranes, etc. In default of a natural head of sufficient power, the head is established in an *accumulator* of power, which is a body of water driven into a reservoir under heavy pressure, by forcing pumps worked by steam. For lighter industries such expedients are unnecessary. In cities in which the water distribution is from elevated reservoirs, and in which the water-supply is sufficiently abundant to justify the application of a portion of it to industrial uses, the water-engine is recommended by the combined advantages of simplicity, neatness, compactness, constant readiness for work, perfect safety, economy while working, and the absolute cessation of expenditure during interruptions and after the work of the day is over.

Fig. 2614 is a form of water-engine in which the water from an elevated reservoir bears upon the pistons of the pump and engine and operates the pump. The slide-valves of the engine and pump are actuated by a lever on the common piston-rod, which is tilted by striking the stuffing-box.

Hy-drau'lic Gov'ern-or. (*Steam.*) Another name for Smeaton's *cataract*. See CATARACT; CORNISH-ENGINE.

Hy-drau'lic Hoist. (*Hoisting.*) One device for this purpose consists of a large cylinder in which the slow and forcible movement of a piston is made to drive water into a smaller cylinder and impart a relatively larger stroke to a piston therein. It is the converse of the hydrostatic press. See ACCUMULATOR, Fig. 24; Figs. *C J*, opposite page 1150; *K L M*, page 1157.

Hy-drau'lic In'di-ca'tor. A gage (*B*, plate opposite page 1150) to indicate hydraulic pressure. Water under the pressure to be tested is admitted through the pipe *a* to a cylinder enclosing a piston which tends to depress the short arm of the lever *b*, counterbalanced by the weight *c*; a movable weight slides on the long arm of the lever, and weights *d* are added to its outer end when a very great pressure is to be measured.

Hy-drau'lic Lift. (*Hoisting.*) An apparatus (*K*, page 1157), on the principle of the hydraulic press, is enclosed within the casing *a*, and is by means of a lever *h* caused to draw upon the chain *e*, which passes over two sets of pulleys, in the example twelve in number, and is thence conducted by leading pulleys over the jib *d*. The weight *c* is by this arrangement raised twelve times the stroke of the ram at each movement of the latter. There is, of course, a corresponding loss of power, but this is of less moment than the increased speed attained.

Hy-drau'lic Lift'ing-jack. (*Hoisting.*) A portable lifting apparatus in which the power is a form of the hydrostatic press (*M*, in same plate). In this form of the machine, the reservoir *a*, pump

Digitized by Google

b, and pressure cylinder *c* are above the ram *d*, and maintained in line therewith by the tubular casing *e*. The plunger *f* is operated by the lever *g*. Water is admitted to the reservoir *a* through the screw-fitted opening *h*, and flows through the valve *i* into the pump-cylinder *b*, when the piston *f* is raised. The downward motion of the piston forces the water through a suitably arranged valve into the lower cylinder *c*, where the pressure it exerts between the head of the immovable ram and the movable pump and reservoir causes them to raise a weight placed either on the head *k* or projecting foot *l*. The machine is re-adjusted for lifting by the screw-valve *m*, which opens a communication between the upper and lower chambers.

M' and *M''* are perspective views of a similar machine.

M''' has a hollow base and a stationary ram which acts as a guide-post. The cylinder with a protruding claw slides upon the ram.

Hy-drau'lic Lime. A kind of lime which has the capacity for hardening under water. See HYDRAULIC CEMENT.

Hy-drau'lic Main. (*Gas.*) A strong, cast-iron pipe, usually about 12 inches in diameter, and of a length sufficient to receive all the perpendicular pipes that convey to it the gas generated in the several retorts. The main is horizontal, and is supported on the brick-work that covers the ovens.

The hydraulic main contains a certain quantity of water, and the mouth of each gas-tube is submerged in the water, so that the gas flows through water and parts with a portion of its ammonia at this stage of the process. See DIP-PIPE; GAS-REGULATOR.

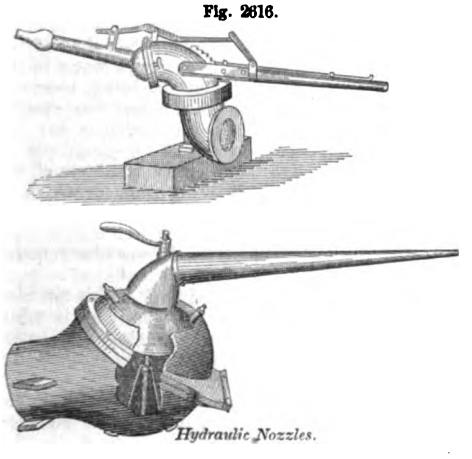
Hy-drau'lic Min'ing. (*Mining.*) A system of mining in which the force of a jet of water is used to wear down a bed of auriferous gravel or earth, which is passed through sluices to detain the particles of gold. See FLUME; HYDRAULIC NOZZLE.

Hy-drau'lic Mor'tar. Mortar in which the presence of alumina enables it to harden under water; producing an insoluble silicate of alumina. (See CEMENT.) It usually contains burned clay along with the more abundant lime, and sometimes oxide of iron. See HYDRAULIC CEMENT; POZZUOLANA.

Hy-drau'lic Mo'tor. A water-engine.

1. A hydraulic ram having connections which raise a piston that is forced down by atmospheric pressure at each cessation of the downward flow of water. By suitably arranged valves the water may be admitted alternately above and below the piston,

Fig. 2616.



Hydraulic Nozzles.

causing a reciprocating action similar to that of the steam-engine.

2. A machine in which a piston is moved in a cylinder by water from a head or stand pipe, in the manner of a steam-engine. Some engines on the Continent of Europe work with a head of 200 feet conducted by a pipe. See HYDRAULIC ENGINE.

Hy-drau'lic Noz'zle. (*Mining.*) A device for directing a stream of water upon a bank of auriferous dirt to crumble it down, that it may be passed through a sluice to collect the gold.

The nozzle has universal motion so as to direct the stream in any direction, in one case by two elbows and pairs of rings which slip on each other, and in the other case by a spherical segment and socket. These machines are made to collect the water of a number of hose-pipes into one stream which may be directed in one jet of from 4 to 7 inches in diameter upon a bank at a distance of 200 feet, if necessary to stand at that distance to avoid caving.

Hy-drau'li-con. (*Music.*) A water-organ. This form was known to the Alexandrian Greeks in the time of Hero, 150 B. C. It is supposed that air was forced by means of water. If so, it was rather a *water-bellows*. See ORGAN.

Hy-drau'lic Piv'ot. (*Machinery.*) A contrivance of Girard by which a film or body of water is introduced below the end of a vertical axis to bear the weight thereof, and prevent the actual friction of the axis on its step.

The hydraulic pivot, or liquid bearing, for stepping vertical shafts, is described in Bramah's planing-machine, English patent, 1802. See JOURNAL-BEARING; PALIER-GLISSANT.

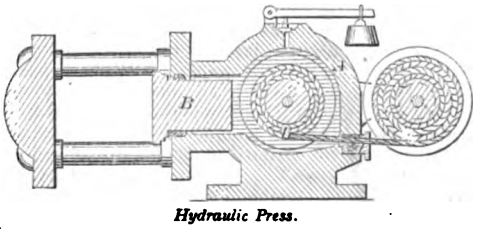
Hy-drau'lic Plat'form-lift. (*Hoisting.*) A form of hoisting-apparatus (*L*, page 1157) in which the small pump *a*, operated by the lever *b*, is caused to force water into the larger cylinder *c*, which contains a piston bearing the upright stem *d*, upon the upper end of which the platform *e e*, sliding upon appropriate guides, is fixed.

Hy-drau'lic Press. Another name for the *hydrostatic press*. *H*, plate opposite page 1150, represents a press for the extraction of liquids from the more solid saturated materials; such as the juices from the woody fiber of herbs in obtaining vegetable extracts.

In this, a horizontal plunger *a*, actuated by a screw *b*, works in a water-chamber *c d* to raise a ram *e*. A vertical screw *f* works in the head *g* on the standards, for raising or depressing the piston, between which and the ram *e* substances are compressed. When the juices of fruits, etc., are to be expressed, the platen is surrounded by a perforated box *j j*. See HYDROSTATIC PRESS.

Another form is that in which a cord or rope is drawn into the box to expand the liquid against the

Fig. 2617.



Hydraulic Press.

sides of the chamber, and thus press outwardly the ram. See STERHYDRAULIC PRESS.

Hy-drau'lic Pro-pel'ler. A mode of propelling vessels by the ejection of a body of water sternward.

Digitized by Google

It was invented by Dr. John Allen, and described by him in 1730. See his "Specimina Ichnographica." His method was to form a tunnel or pipe, open at the stern of the vessel, and by means of a pump to force water or air through it into the sea. The reaction thus occasioned would drive the ship forward. The design was put into execution upon a canal, with a boat of considerable size, and worked by pumps by manual labor, but he suggested the employment of a steam-engine, and its application to a vessel of 1,500 tons.

The hydraulic propeller of Dr. Allen formed the subject of a patent to David Ramsey, in England, 1738; and Rumsey, of America, 1782. The latter ran a vessel of 50 feet long on the Potomac, and one built on his plan was launched and fitted after his death, and ran on the Thames four miles an hour against wind and tide.

Dr. Franklin planned a boat of this kind in 1785, and it has since been tried on the Scheldt, two turbines being used for pumps.

Linnaker's hydraulic propeller, 1808, had pumps placed horizontally beneath the bottom of the vessel. The pistons were attached to hanging levers which were oscillated by the power of the steam-engine. The pistons reciprocated in longitudinal trunks parallel to the keel.

In a second plan, the pumps were vertical and discharged the water through horizontal trunks.

The "Nautilus," furnished with Ruthven's propeller, had a trial trip on the Thames in the summer of 1868, running in company with paddle-wheel steamers of the class that ply like aquatic omnibuses up and down the river. She ran at the rate of 13.5 and 7.2 miles per hour, with and against the tide, respectively, or at an average speed of 10.35 miles per hour. She then steamed down the river, and when off the Tunnel pier, with both strong wind and tide in her favor, going at full speed, was made, by reversing the valves, to stop dead in less than ten seconds and in about a quarter of her length. Her Majesty's iron-clad gunboat "Waterwitch" was fitted with the new propeller. The water is discharged in a heavy stream on both sides of the vessel, and its direction is under such command that the vessel is independent of her rudder, and is worked under the complete control of the master, officer of the watch, or man on deck, without any communication with the engine. The plan has been tried in the United States without commending itself as against the paddle and screw. Different modes of the application of the hydraulic propeller have been suggested for canal navigation.

Hy-drau'lic Pull'ing-jack. (*Hoisting.*) An application of the hydrostatic press.

A cylinder *a* (*C*, plate on the opposite page) contains a tube *b*, to which the piston *c* is attached. *d* is a smaller tube sliding within the piston and tube *b*. A valve *e* closes the communication between the cistern *f*, which contains a pump *f'* operated by the hand-lever *h*, and the cylinder *a*; two passages *g g* afford communication between the tube *d* and cylinder *a* at the back of the piston *c*. Water is poured into the cistern through an opening closed by a screw, and the jack suspended cistern end downward. Working the hand-lever *h* forces, by means of the plunger *h*, water through the tube *d* and passages *i i*, and depresses the piston to the bottom of the cylinder *a*. The water at the back of the piston returns at the same time to the cistern through the passages *g g*. By unscrewing the stop-valve *e*, the water returns through the tube *d* and passages *i i* to the cistern, relieving the piston from pressure and allowing a suspended weight to fall.

Hy-drau'lic Punch. An application of the hydrostatic press, comprising a force-pump and operating cylinder (*G*, same plate), in which the piston, carrying the punch *b*, is inserted, inclosed in a case *a*. The lever *e* operates the pump to depress the piston, and force the punch through a plate beneath; it is then raised by the lever *d* to punch another hole. A PUNCHING-BEAR (which see).

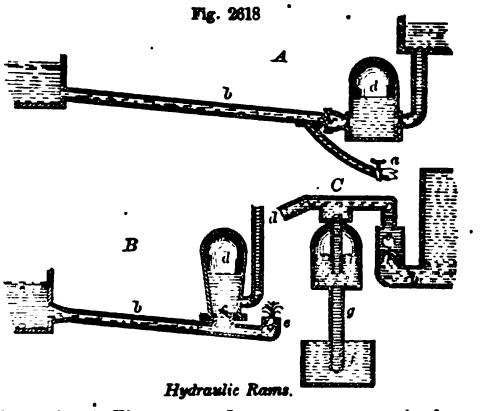
Hy-drau'lic Rail-bend'er. An implement for bending or straightening rails by hydraulic pressure (*E*, same plate). The action of the lever *a* operates a small force-pump within the casing, which is connected with a larger cylinder, the piston of which forces the plunger *d* against the rail midway between the points where it is held by the lips *c c*. Known as a JIM-CROW (which see).

Hy-drau'lic Ram. A device by which the fall of a column of water in a tube is caused to elevate a portion of itself to a hight greater than that of its source.

This depends on the well-known law of mechanical force, that the effect produced by a body is as its weight multiplied into the velocity, its absolute force constituting the momentum.

This principle was first practically applied in the construction of the water-ram by Mr. Whitehurst of Derby, England, in 1772. Whitehurst's ram is

Fig. 2618



Hydraulic Rams.

shown in *A*, Fig. 2618. It was not automatic, but depended upon the opening and shutting of a cock from which water for domestic purposes was drawn.

The operation is as follows: on opening the cock *a*, water from the cistern flowed down the pipe *b*, and on closing the cock, the sudden stoppage of the water caused the valve *c* to open, and a part to be forced through into the air-chamber *d*; the momentum imparted to the water would be sufficient to carry it to a hight as much greater than that of the descending column as the quantity of water in the former was less than in the latter; being, however, forced into the air-chamber, this effect was exerted intermediately through the compression of the air, rendering it more constant.

In 1796, Montgolfier, one of the inventors of the balloon, invented the self-acting ram, for which he obtained a gold medal at the French Exposition of 1802. This is absolutely automatic, maintaining its action regularly so long as the machine remains intact or the supply of water holds out.

A simple form is represented at *B*. This machine differed from that of Whitehurst merely in the addition of a waste-valve *c*; but this altered its entire character, and rendered it practically efficient as a water-raising machine.

The water, as before, flows down the pipe *b*, but the momentum thus acquired causes it to raise the

Digitized by Google

valve *e*, shutting off the water as before and causing it to spend its energy in forcing a portion of itself into the chamber *d*; but this done the valve drops, causing a flow through the pipe until the water has gained energy to again raise the valve, when the same series of events is repeated.

C represents the suction-ram; in this the water flows from the reservoir along the pipe *b c d*, having a ball-valve *e*; the water flowing from the reservoir through the pipe finally lifts the valve sufficiently to close the aperture *c*, stopping the flow while the pipe is discharged through *d* and creating a vacuum therein; the atmospheric pressure on the water in *f* now causes it to rise through the pipe *g* and be discharged by *d*. The ball-valve then drops by its gravitation to be again elevated by the current through the pipe, and the series of operations is continued.

The water-ram is only efficacious where there is a larger supply of water at command than is necessary to be raised, but in certain cases its power and constant and unfailing action render it very valuable.

Hy-drau'lic Shaft-straight'en-er. An hydraulic implement for straightening metallic bars and shafts (*F*, plate opposite page 1150). The beam *a* and shaft *b* are each inserted within the collars *c c*, and pressure applied through the plunger *d*, operated by a small hydraulic press enclosed within the casing *e* and worked by the lever *f*.

Hy-drau'lic Shears. A machine for shearing metals, etc., by the force of water-pressure (*O*, page 1157). The cutting-blade *a* is forced toward and drawn away from the stationary blade *b* by its attachment to the piston of a cylinder connected with a force-pump contained within the casing *c* and operated by a lever *d*.

Hy-drau'lic Slip. A slip-dock in which the cradle and its load, the ship, are hauled up the rails or ways, for the purpose of cleaning or repair, by the power of an hydraulic press. See SLIP-DOCK.

The cylinder of the press lies on a strong foundation at the upper end of the slip-way; its plunger has a *cross-head* connected by means of side-rods with a *cross-tail*, to which is attached the chain for hauling up the cradle. The chain consists of a series of long, straight links, or traction rods, each equal in length to the stroke of the plunger and connected together by pins. The plunger is driven by water, forced in by a set of pumps worked by a steam-engine. After a forward stroke of the plunger has been completed, an escape-valve is opened for the water, and the plunger is drawn back by a counterpoise; one length of traction rod is disconnected and taken out; and when the plunger has completed its return stroke, the shortened chain of traction rods is again connected with the cross-tail, to be ready for the next forward stroke, and so on. The operation of disconnecting the traction rods, taking out a length and reconnecting them, is called *fleeting*. The usual speed with large ships, including stoppages for *fleeting*, is about 4 feet per minute.

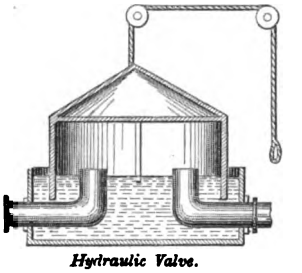
Hy-drau'lic Spring-test'er. An application of the hydrostatic press to testing the strength of springs (*P P'*, page 1157). *a* is a side view and *b* the plan of this device. It has an accumulator, into which air is forced by means of a hand-pump until the pressure is about 100 pounds per square inch. Power-pumps working in a cistern are then set in motion, pumping water into the cylinder until a pressure of about 300 pounds per inch is attained; by opening a stop-valve, this accumulated pressure is at once allowed to act on the ram and compress the spring to be tested. The ram is retracted by counterbalance weights when the pressure is removed.

Hy-drau'lic Tel'e-graph. A mode of communication by means of a column of liquid in a pipe, which is caused to move so as to actuate a hand, or by different levels to indicate messages or letters on a graduated or written scale against the fluctuating column. The plan was tried in France by Bossuet over a century since, with a pipe about three miles long.

Vallance's hydraulic telegraph was described by the inventor in a pamphlet in 1825.

Hy-drau'lic Valve. (*Pneumatics.*) An inverted cup which is lowered over the upturned open end of a pipe, the edge of the cup being submerged in water and closing the pipe against the passage of air.

Fig. 2619.



Hydraulic Valve.

The hydraulic valve of the gas-works governs the communication between the gas-holder and the main. When the valve is raised the communication is free between the two pipes; but when the valve is depressed the division plate descends into the water and closes the connection.

Hy-drau'lic Wheel. One for raising water by applied power, as the NORIA, SCOOP-WHEEL, TYMPANUM, etc. (which see). The wheel shown in the example is driven by steam or wind power, having buckets on its internal perimeter which raise water from the stream and discharge it right and left into the branches of the elevated gutter. It is intended for irrigating cotton, coffee, indigo, rice, and sugar lands, and for other purposes. See Fig. 2620.

Hy'dro-ba-rom'e-ter. An instrument for determining the depth of sea-water by its pressure.

In the United States Coast Survey Report, 1857, pp. 398 – 403, is an account of the sounding-apparatus of Lieutenant E. B. Hunt: "Arrange a weighted india-rubber air-vessel for dragging on the bottom; connect this with a boat or surveying-vessel by an air-tight tube of small bore; let this tube open in a cistern of mercury made air-tight; and from this cistern arrange a vertical glass column, open at the top, through which the mercury can rise to any hight required by the pressure due to the depth."

See also Ericsson's patent, September 22, 1863. Also McCord's, September 20, 1859, in which latter the pressure of the water pushes up a piston into a graduated cylinder, where the acquired elevation is registered.

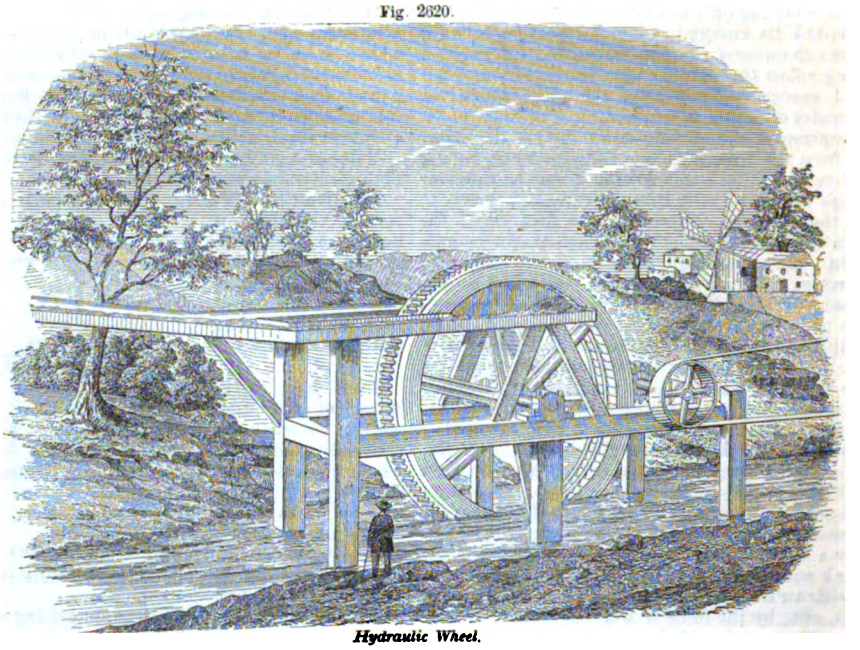
Hy'dro-car'bon-burn'er. One in which liquid fuel is used beneath a steam-boiler, cooking-vessel, or otherwise. It usually has a jet of air or steam, frequently both, which carry with them a quantity of petroleum or coal oil in the form of spray which is ignited and burns below the boiler. Ingenuity is exercised in so arranging the burners that the jets in sufficient number are so disposed as to apply the flame to the surfaces of the boiler.

In Fig. 2621, the pipe *B* is a receptacle in which the oil is mixed with air, and the gases evolved. A small stream of oil enters by the pipe *i*, a current of air by opening *r*, and a jet of steam from the boiler by pipe *S*. Pipe *B*, containing steam, air, and gas, passes through the furnace, and on its return empties its heated contents in the midst of the fire.

In heating or cooking stoves, the burner may consist of a vaporizer in which a jet heats a small retort from which the coal oil issues in a vapor; or

Digitized by Google

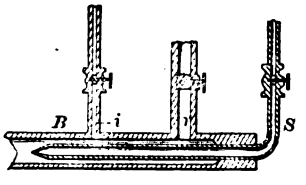
Fig. 2620.

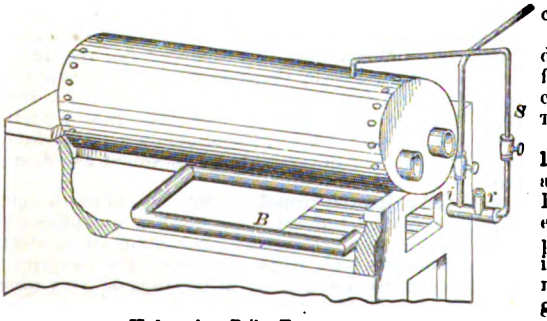


Hydraulic Wheel.

it may be pan of sand upon whose surface the oil is ignited. See GAS-HEATER; GAS-STOVE.

Fig. 2621.





Hydrocarbon Boiler-Furnace.

Hy'dro-car'bon – fur'nace. One specially adapted to the use of liquid fuel either beneath a steam-boiler or a metallurgic furnace. See HYDRO-CARBON-BURNER.

Hy'dro-car'bon-stove. A heating or cooking stove in which liquid fuel is burned within the furnace chamber. See GAS-STOVE.

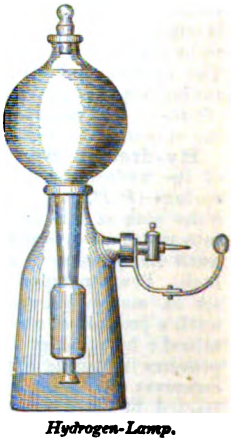
Hy'dro–e-lec'tric Bat'ter-y. (*Electricity.*) An apparatus in which dynamic electricity is produced by means of two different metals connected together by a conductor, and immersed in a solution which causes a flow of electricity from the positive to the negative metal. See GALVANIC BATTERY.

Hy'dro–e-lec'tric Ma-chine'. (*Electricity.*) A machine invented in 1840 by Mr. (now Sir William) Armstrong, in which electricity is generated by the friction of steam against the sides of orifices through which it is allowed to escape under high pressure. A steam-boiler is supported on four glass legs. The steam is conducted over wet cotton wicks before escaping, in order to take up water whose friction against the sides of the orifice is the generator of the electricity, the steam being the driving power. The positive electricity is collected by directing the jet of steam upon a metallic comb communicating with an insulated conductor.

Hy'dro–ex-tract'or. A form of filter or dryer in which a liquid is driven by centrifugal force from or through a mass deposited in a chamber rotating at high velocity. See CENTRIFUGAL MACHINE.

Hy'dro-gen-lamp. About 1825 a German named Döbereiner discovered that spongy platinum became incandescent when a mixture of hydrogen gas and atmospheric air was passed through it, and thence devised his self-lighting lamp, which was long in favor and known as the hydrogen-lamp. It formed an instantaneous light apparatus, and was especially useful for lighting at intervals during the day.

Fig. 2622



Hydrogen-Lamp.

It has lately been applied to gas-burners,

Digitized by Google

which are self-igniting as the jet of carburetted hydrogen is ejected upon a piece of spongy platinum suitably placed in proximity to the orifice.

Hy'dro-met'al-lur'gy. The wet process of extracting metals from ores; in contradistinction to the hot process. See list under METALLURGY.

Hy-drom'e-ter. 1. An instrument for determining the relative densities of liquids. Distilled water is usually referred to as the standard of comparison. It consists essentially of a bulb or float weighted at bottom so as to float upright, and having an elongated stem graduated to indicate the density of the liquid by the depth to which it sinks therein. Hydrometers may be divided into two classes; those with which weights are used and those in which they are dispensed with. Among the former are Sykes's, Jones's, and Siemen's, while Tralle's and many others are of the latter description.

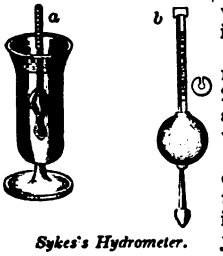
In all, a correction must be applied to the observed indication when the temperature is above or below a certain standard (usually 60° Fah.), in order to obtain the true result.

Many instruments are only constructed with reference to liquids heavier than water; such are *saccharometers*, *salinometers*, and *acidimeters*, which, though bearing names, specifically indicating the particular kinds of fluids they are designed to test, are embraced in the general class hydrometer; such also are those adapted for fluids lighter than water, as *alcoholometers* and *oleometers;* all depend on the same principle, but greater delicacy is secured by confining the measuring capacity of the instrument within comparatively narrow limits, allowing it much greater vertical ranges for equal variations in specific gravity, so that extremely small differences become sensible. The different weights in those of the weighted class are also intended for this purpose.

Hydrometers are made and specially graduated for testing spirits, petroleum, oil, milk, cream, vinegar, lye, lime-water, acid, ether, alcohol, silver solution, dye solutions, salt water, lime, alkali, sirup, ammonia, beer, bark ooze, cider, shellac, glue, wine, must, urine. See list under METERS.

Sykes's hydrometer is that legally employed in the collection of the revenue in Great Britain. It has a flat stem graduated into eleven equal parts, which are again subdivided into two.

Fig. 2628.



Sykes's Hydrometer.

Eight different weights, numbered respectively 10, 20, 30, 40, 50, 60, 70, 80, are employed in connection with the instrument.

The proper one to be used depends on the strength of the spirit to be tested. It is placed on the lower projecting stem, sinking the instrument to a depth corresponding or nearly so to some one of the graduations on the upper stem; this is noted, and also the temperature of the liquid, and the corresponding strength per cent of spirit is then found from tables constructed for the purpose.

Jones's hydrometer is a modification of Sykes's. It has a square stem, differently graduated on each of its four sides, and three weights which, with the unweighted instrument, correspond to the four scales.

Among those in which weights are dispensed with are Beaumé's, the centigrade, etc.

Beaumé's is in very general use in France and on the Continent of Europe. Its scale is based upon a solution containing 10 per cent of chloride of sodium (common salt).

The following table shows the specific gravity corresponding to different degrees of Beaumé: —

For Liquids heavier than Water.

Degrees Beaumé.	Specific Gravity.	Degrees Beaumé.	Specific Gravity.	Degrees Beaumé.	Specific Gravity.
0	1.000	26	1.206	52	1.520
1	1.007	27	1.216	53	1.535
2	1.013	28	1.226	54	1.551

26	.901	43	.816	60	.745

In Gay Lussac's centigrade hydrometer the specific gravity of a liquid heavier than water is found by subtracting the indication from 100 and dividing 100 by the remainder; if lighter than water, add the indication to 100 and divide 100 by the sum, thus 10° below 0° = $\frac{100}{90}$ = 1.111 specific gravity; 10° above 0° = $\frac{100}{110}$ = 0.909 specific gravity.

The hydrometer of Brix is that legally used in Prussia; to ascertain the specific gravity the constant number, 400, is divided by 400 + the indication for liquids lighter than water, and by 400 − the indication for those heavier than water.

The formula for Beck's instrument is precisely similar, substituting 170 for 400.

Digitized by Google

Tralle's and Gendar's are used in the United States, the former being adopted by government for ascertaining the duty on distilled spirits. It is graduated from 0°, the indication in water, to 100°, alcohol, 50° being proof spirit. A correction is required for temperatures above or below 60° F.

The volume of pure spirit is ascertained (1) when above proof by multiplying the indication by 2 and subtracting 100; and (2) when below proof by multiplying the indication by 2 and subtracting the product from 100.

The commercial hydrometer, Gendar's, is graduated to 100° each way from proof. To ascertain the per cent of pure spirit: when the liquor is above proof, add 100 to the indication and divide the sum by 2; when below proof subtract the indication from 100 and divide the remainder by 2.

Rousseau's hydrometer, designed for ascertaining the specific gravity of very small samples of liquids, has a cup on the upper part of the stem in which a known amount, as one gramme, of the fluid is placed; the degree of submergence of the stem compared with that caused by an equal volume of distilled water gives the density of the fluid.

There are also hydrometers which indicate the density by means of a steelyard, having on one arm a vessel which is *in equilibrio* in a tank when empty. The mark on the other arm of the scale, at which the weight must be placed to maintain the equilibrium when the vessel is filled with liquid, determines its specific gravity.

Twaddel's hydrometer is used in England for liquids heavier than water. Its degrees are converted into specific gravities by multiplying them by 5, adding 1,000, and dividing the sum by 1,000. Thus, —

$$20° \text{ Twaddel} = \frac{20 \times 5 + 1{,}000}{1{,}000} = 1.100$$

The density of liquids may also be determined by means of a series of glass beads of different specific gravities; the heavier sink and the lighter float on the surface, while one that indicates the precise specific gravity, which is marked in thousandths on its surface, remains in equilibrium at any depth in the liquid.

The subject is fully discussed in Kuppfer's "Handbuch der Alkoholometrie," Berlin, 1865.

See also ALCOHOLOMETER, ACIDIMETER, AREOMETER, SACCHAROMETER, etc. See list under METER; see also UNIT.

The most familiar hydrometer, to many, is a hen's egg, used by a farmer's wife to test the strength of lye for making soap. When it floats as large as a quarter-dollar above the liquid the strength is satisfactory. Others test it by its action on a feather.

Small hollow glass spheres called bubbles are also used in testing spirits, the rate at which they ascend therein being a gage of the gravity of the liquid.

The hydrometer was in all probability invented by Archimedes, who was killed in the storming of Syracuse, 212 B. C. His discovery of the mode of ascertaining specific gravity by displacement of liquid is referred to by many writers of Europe, Asia, and Libya.

Seneca, Pliny, and Galen, who flourished during the first and second centuries of our era, and whose writings refer to the methods then in use of ascertaining the specific gravity of solids and fluids, appear unacquainted with the hydrometer, though the instrument is clearly described by Priscian, who died about A. D. 528.

Synesius of Ptolemais wrote to Hypatia that he wished to use a *hydroscopium*, and requests that she would cause one to be constructed for him. He says, "It is a cylindrical tube, the size of a reed or pipe, a line is drawn upon it lengthwise, which is intersected by others, and these point out the weight of water. At the end of the tube is a cone, the base of which is joined to that of the tube, so that both have but one base. This part of the instrument is called *baryl'ion*. If it be placed in water it remains in a perpendicular direction, so that one can readily discover by it the weight of the fluid."

Hypatia was brutally murdered by a mob of Alexandrine monks, instigated by Cyril, A. D. 414. With the death of Hypatia expired another period of intellectual research. Cyril was the president of the council which condemned Nestorius. After a dreary interval of several centuries, philosophy again revived in the city of Alexandria, while the Papacy shrank out of Asia and Africa, ejected from the great capitals Antioch, Jerusalem, and Alexandria; the Nestorians became the tutors of Mesopotamia and Chaldea, and in connection with the Jews founded colleges. Among these, that of Djondesabour first instituted a system of academical honors which has descended to our time. This college was patronized by the Khalif Haroun al Raschid, who forbade any one practicing medicine until after a satisfactory examination at the college of Djondesabour or that of Bagdad.

The areometer used by the Saracens about A. D. 1000, and for many centuries, was a form of hydrometer. It is described by Abu-Jafar Al-Khâzinî, an eminent Saracenic writer of the twelfth century, and is credited to Pappus, a Greek philosopher, who was contemporary with Theodosius the Great, A. D. 379–395. Al-Khâzinî refers to the original discovery of Archimedes, upon which the instrument is based, and takes a very pious view of the line of discovery. See the "Book of the Balance of Wisdom," in Vol. VI. of the "Journal of the American Oriental Society," New Haven, 1860. See *supra*, pp. 141, 142.

In the sixteenth and seventeenth centuries, the salinometer was used in the salt-works of Germany, and is referred to as a well-known invention. Pepys, in his "Diary," December 10, 1668, refers to Boyle's hydrometer as "a bubble to try the strength of spirits with."

2. A current gage; known also as a *tachometer*, *rheometer*, *hydrometric pendulum*, *Woltmann's mill*, etc.

Hy'dro-met'ric Pend'u-lum. A *current-gage*. An instrument consisting of a ball suspended from the center of a graduated quadrant, and held in a stream to mark by its deflection the rate of motion of the water.

Hy'dro-met'ro-graph. An instrument for determining and recording the amount of water issuing from a pipe, etc., in a given time.

Hy'dro-phore. An instrument for obtaining specimens of water from any given depth below the surface.

Hy'dro-scope. 1. An instrument anciently used for measuring time by the trickling of water from an orifice in the lower end of a graduated tube. The hight, diameter, and graduation of the tube, and the size of the opening, being properly proportioned, the subsidence of level of the water indicates the passage of time. See CLEPSYDRA.

2. An instrument to detect the presence of moisture in air. See HYGROMETER.

Hy'dro-stat. A general term, signifying an apparatus or contrivance to prevent the explosion of steam-boilers. The devices are numerous, and have specific names.

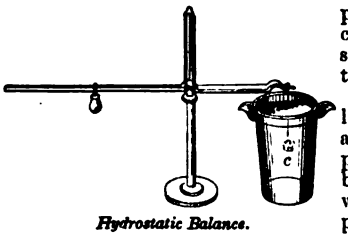
Hy'dro-stat'ic Arch. (*Architecture.*) A linear

Digitized by Google

arch suited for sustaining normal pressure at each point, proportional — like that of a liquid in repose — to a depth below a given horizontal plane. It is sometimes called the "Arch of Yvon-Villaceaux," from the name of the mathematician who first demonstrated its properties. — RANKINE.

Hy'dro-stat'ic Bal'ance. A balance for weighing substances in water for the purpose of ascertaining their specific gravities.

Fig. 2624.



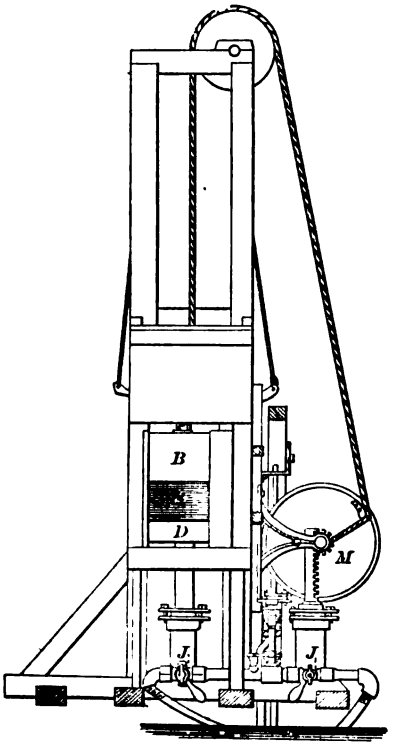
Hydrostatic Balance.

When unloaded, the arms are equipoised. *c*, the body to be weighed, is suspended from the shorter arm. On the longer arm the movable weight indicates the weight of the object in air or water. A *specific-gravity balance.* See AREOMETER.

Hy'dro-stat'ic Bal'ing-press. One in which the force of water under pressure is made to compress the fibrous material to be baled.

In the example shown, the beater *B* is first operated, and, when the process has gone to a certain extent, the beater is made stationary, and the follower *D* raised. Both operations are effected by hydraulic

Fig 2625.

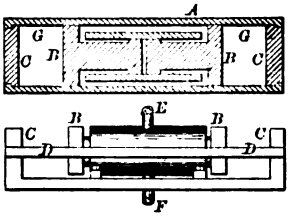


Hydrostatic Baling-Press.

operation. The suspension rope of the beater winds on the wheel *M*, which is rotated by pinion and rack, the latter being depressed by a piston in cylinder *J*. The rope is tripped off the wheel from time to time, automatically, allowing the weight *B* to fall, and again and again re-winds and slips off. At the proper time the cock is turned and the water turned on to the other cylinder *J*, beneath the follower *D*, and the latter is raised by the pressure of water beneath the piston in said cylinder. *G* represents the material under pressure.

In Fig. 2626 the motive-power is water under pressure. The cylinder *A* is open at both ends, has two ports, *E* and *F*, at the center, to receive and discharge respectively the water from the pump or head. There are two rams *B* in cylinder *A*, working in opposite directions toward heads *C*. *G* is the space for the material to be pressed. *D* are connecting-rods, connecting the heads *C* together to resist the strain of the rams *B*, and forming guides for the rams.

Fig. 2626.



Hydrostatic Baling-Press.

Hy'dro-stat'ic Bed. A bag of india-rubber cloth inflated with water. Intended for bedridden or wounded persons; invented by Dr. Arnott, and described in his "Elements of Physics."

Hy'dro-stat'ic Bel'lows. An instrument for illustrating the fact that the pressure of a small column of water balances that of another column of water, no matter how large. Water poured into the funnel-mouthed tube *a* (*I*, plate opposite page 1150) flows into the flexible-sided box *b*, and raises a weight *c* many times greater than its own. The weight may be lifted in this way until the combined pressure of it and the column of water in the bellows *b* is equal to that of a column of water having an equal surface and as high as the column in the tube *c*.

Bramah's and other hydrostatic or hyraulic presses depend on this principle.

Hy'dro-stat'ic Lamp. A lamp in which a supernatant stratum of oil is sustained by water or other fluid of greater specific gravity than the oil. Salt and water, sirup, honey, mercury, and sulphate of zinc in solution, have been employed for this purpose.

Hy'dro-stat'ic Lev'el. (*Civil Engineering.*) A water-level. See LEVEL.

Hy'dro-stat'ic Press. A machine in which the pressure of a piston on a body of water of relatively small sectional area is made to propagate the force to a cylinder of multiple area, where the force is directly as the difference and the speed inversely as the difference.

Pascal (1650) demonstrated the power of a column of water in a vertical pipe inserted into a barrel. In filling the barrel and pipe, he found the pressure to be as the hight of the column and the area of the base, as if the cask had preserved its diameter throughout the whole length of the column. Supposing the barrel to have an area of three square feet, and the pipe of twelve feet length to have a capacity of two pints, the effective pressure of the quart of water on the heads of the cask is equal to a cylinder of water containing thirty-six cubic feet.

If a properly fitting piston of a weight equal to the quart of water be placed in the pipe, it will have the same effect as the water for which it is a substitute.

Digitized by Google

If, instead of the mere weight of the piston, it be loaded with a weight nine times that of its own, the bursting pressure in the barrel will be tenfold greater than before.

If, instead of a weight upon the piston, a lever be placed above it, the increased force may be immensely multiplied and a power obtained which is beyond all others of equal compactness and facility of manipulation.

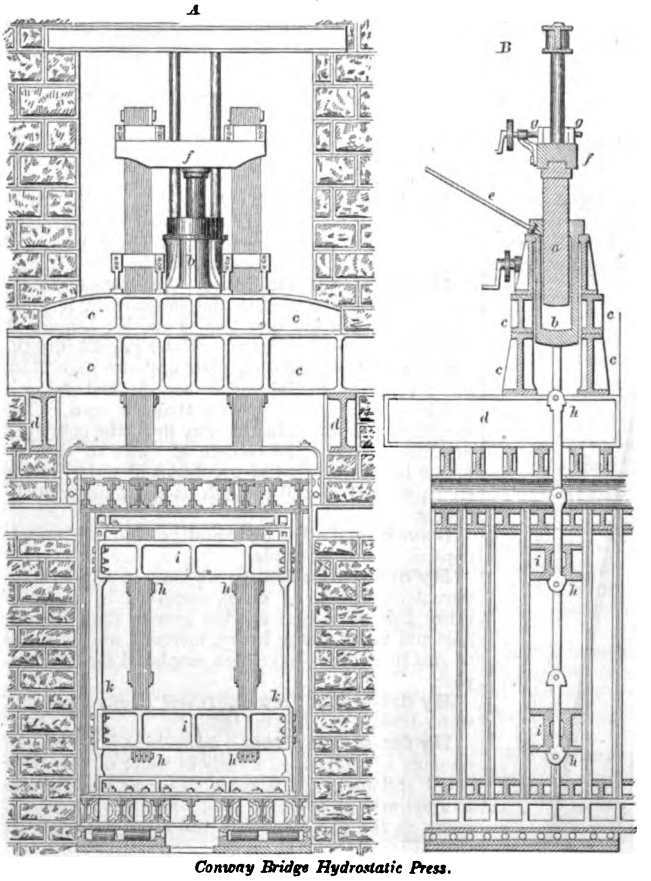
This is the Bramah hydraulic press.

The first one ever made is in the museum of the Commissioners of Patents (England), and is inscribed, "Bramah, Invt. et fect. 1796."

The celebrated Maudslay was mechanically educated in Bramah's shop.

In *N* (page 1157) the operation of this machine may be readily understood. *a* is a reservoir of water on which is a pump, the piston-rod *b* of which is worked by the hand-lever *c*. The water is conveyed by the pipe *d* to the cylinder *e*, where it elevates the piston *f* and table *g*, which rises between the guides that hold the upper plate, against which the object under pressure is driven. The elevation of the table *g* is proportionate to the quantity of water injected. The power is proportionate to the respective areas of the pump and the cylinder *a*.

Fig. 2627.



Conway Bridge Hydrostatic Press.

Fig. 2627, *A* is an elevation of the press and cross-section of the tube employed in the Conway tubular bridge, and *B* a vertical section of the press and a portion of the tubing. *a* is the pump piston and *b* the cylinder, which is supported upon double iron girders *c c*, resting on girders *d*, built in the masonry. Water is forced through the pipe *e* into the cylinder by an engine of 40-horse power. The piston has a cross-head *f* provided with clamps *g* which hold the ends of the lifting chain links and are screwed up firmly against them. The alternate links are notched, as shown at *h h*, so as to fit into corresponding grooves in the cross-girders *i i*, which are temporarily bolted to the walls *k k* of the tube. The force actually exerted by the pump in raising one end of the tube, a weight of 900 tons, was two and a quarter tons per square inch.

Three hydrostatic presses were used at the raising of the tubes of the Menai Railroad Bridge. One of them worked at one end of the tube and two smaller ones at the other end. The larger one had a cylinder 11 inches thick and 20 inches in internal diameter. Its lift was 6 feet. The weight of the cylinder was 16 tons, and of the machine 40 tons. Its power was estimated as equal to that of 30,000 men. The smaller presses had rams 18 inches in diameter.

The presses stood on the summits of the piers, and lifted by means of chains having alternately eight and nine links. The weight of a chain was 224,000 pounds. They were attached to the rams by iron cross-heads of great thickness. The two chains passed through square holes at each end of the cross-head, and were gripped above by clamps of wrought-iron, screwed like a vise. At the lower end, the chains were attached to the tube, or rather to lifting-frames within its extremities, by three sets of massive cast-iron beams, crossing one above another, and secured by wrought-iron straps passing over the upper pair and descending into the bottom cells where they were keyed. The ends of the chains fitted under deep shoulders or notches in the lifting-frames, where they were secured by screw-bolts; these lifting-frames and beams added 448,000 pounds to the weight to be lifted. Each of the middle tubes weighed 4,032,000 pounds (1,800 English tons), and they were lifted by successive lifts of 6 feet to a hight of 100 feet above tide-water. The motive force was two steam-engines of 40-horse power each, and the water was delivered through a ½-inch pipe into the cylinder below the ram.

That shown at *D*, plate opposite page 1150, is adapted for pressing the printed sheets of books, etc. It is arranged with either one or two pumps for forcing water into the lifting-cylinder, whose piston raises the platform on which the sheets are placed. This is kept in horizontal position by upright standards, and between it and the head of the press the sheets are compressed.

In the *steyhydraulic* press of MM. Desgoffe and Olivier, a coil of gut-rope passing through a stuffing-

APPLICATIONS OF THE HYDROSTATIC PRESS.

Digitized by Google

box into the cylinder is wound upon an interior pulley, displacing part of the fluid (oil) and causing the piston to rise. See HYDRAULIC PRESS, Fig. 2617. Among the applications of the hydrostatic press may be found : —

Accumulator.	Hydraulic slip.
Boiler-power.	Hydraulic spring-tester.
Coal-breaking jack.	Hydrostatic baling-press.
Crank-puller.	Hydrostatic bellows.
Hydraulic crane.	Jim-crow.
Hydraulic dock.	Pipe-prover.
Hydraulic elevator.	Punching-bear.
Hydraulic hoist.	Rail-bender.
Hydraulic lift.	Rail-punch.
Hydraulic lifting-jack.	Shaft-straightener.
Hydraulic platform-lift.	Ship-jack.
Hydraulic press.	Spring-tester.
Hydraulic pulling-jack.	Testing-machine.
Hydraulic punch.	Traversing-jack.
Hydraulic shaft-straightener.	Wagon-tipper.
Hydraulic shears.	Wheel-jack.
	Wheel-press.

Hy'dro-stat'ic-press Pump. A pump used in hydrostatic presses. The example (*A*, plate opposite page 1150) gives one form. *q* is the water-cistern and *r* the pump-barrel, which has a sucking tube *t* and a conical valve *s*. The plunger is operated by the lever, which may be pivoted in either of the holes shown at *x* on the standard, to obtain greater or less quickness of stroke ; it is connected with the standard by a link. *k* is a safety-valve and *z* the discharge-valve, the rise and fall of which is regulated by a screw placed over it. On lifting the plunger, water is drawn into the barrel *r* through the tube *t*, and by depressing it the water is forced out through the pipe *j*, the valve *z* rising to permit its passage. See also *C D*, same plate.

Hy-et'o-graph. A chart indicating the comparative distribution of rain over a given geographical surface. See list under 'GRAPH. See also MAP, for list of lines indicating equal conditions of natural phenomena.

Hy'gro-graph. A recording hygrometer.

Hy'grom'e-ter. An instrument for measuring the comparative moisture of the air.

They are of three kinds : —

1. Those which act on the principle of *absorption*.
2. Those which act by *condensation*.
3. Those in which the hygrometric condition is deduced from observations of a wet and a dry bulb.

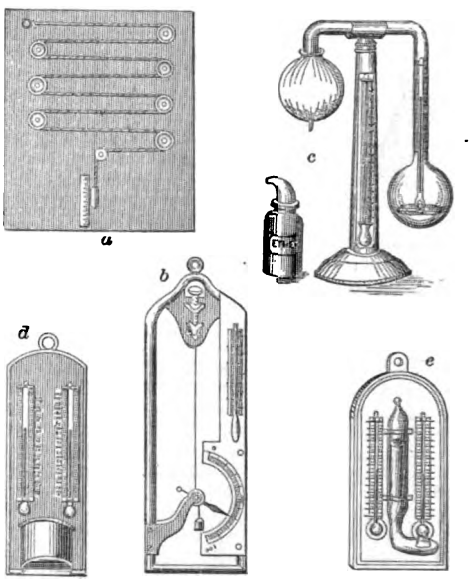
1. *a*. Of the first class is the *hygrometer* of Saussure (died 1799). It consists of a human hair boiled in lye, and acts by absorption and evaporation, as shown at *a*, Fig. 2628. A piece of catgut may be made to extend from a pin at one end, over a number of pulleys, and terminate at the lower end with a small weight, which rises and falls with changes in the length of the cord, induced by hygrometric changes in the atmosphere.

A hygrometer, or *weather prophet*, may be constructed by taking a cigar-box and inserting at its center an upright pivoted shaft with two horizontal arms. Around this are wound two turns of a catgut string, one end of which is fastened to a staple at one end and the other to a spiral spring at the other end of the box.

Fluctuations in atmospheric humidity cause the string to extend or contract, as the case may be, turning the shaft partially round. If to the end of one arm a toy figure of a mower be attached, and to the other a figure holding an umbrella, openings being cut to represent doors in the side of the box, fronting each figure, the figure holding the umbrella will come out when the air is moist and retire as the weather becomes dry, allowing the mower to come forth.

In *b*, a human hair is fastened at the upper end to a screw, and at the lower end passes over a pulley which has a radial pointer. A weight keeps the

Fig. 2628.



Hygrometers.

hair tight, and its expansion or contraction causes the pointer to traverse on the graduated arc. Moisture makes the hair longer, and allows the pointer to rise, and dry weather has the reverse effect. The 0° and 100° form the extremes of dryness and wetness: one is obtained from an atmosphere artificially dried, and the other by the absolute saturation of the air with moisture. The intervening space is then divided into 100 equal parts.

b. An alcoholic solution of camphor, saltpeter, and muriate of ammonia, in a glass tube, has been suggested for a weather guide. Changes of weather are stated to render the solution turbid, or clear it, as the condition may be. Its value is doubtful.

c. An arm is balanced upon an axis so as to be horizontal at the zero point, and provided at one end with an absorbent substance, such as a piece of sponge. When the air is relatively moist the sponge will absorb water and become heavier, so that the pointer rises against the graduated arc and indicates rain ; conversely, dry air causes the sponge to part with some of its moisture, and, becoming lighter, the pointer falls.

2. Daniell's hygrometer *c* determines the moisture of the air by indicating the dew-point, or the temperature at which moisture is deposited by the air. It consists of a bent tube of glass with a bulb at each end. The legs of the tube are of unequal length, and the lower one, which is of black glass, contains a little ether, into which dips the bulb of a small and delicate thermometer, whose stem occupies the cavity in the leg of the tube. The whole tube contains ether and its vapor, the air having been removed. The upper bulb is covered with a piece of muslin. The support of the instrument has another thermometer by which the temperature of the air is denoted.

Digitized by Google

When an observation is to be made, a little ether is poured upon the muslin; this evaporates and cools the contents of the tube, abstracting heat from the lower bulb by the vaporization of its contents. As soon as the lower bulb has cooled sufficiently to condense the moisture of the atmosphere, dew will be observed to condense upon it, and the temperature is to be noted as indicated by the thermometer in the tube. If the air be moist, dew will commence to deposit on the lower bulb on a slight reduction of temperature; if the air be dry, it will require a relatively greater reduction of temperature. The point at which moisture commences to form on the bulb is the "dew-point," and this ascertained, in connection with the temperature of the air, will enable the hygrometric condition of the air to be determined by tables prepared for the purpose; as to the elasticity and density of the aqueous vapor, its weight in a cubic foot of air; the degree of dryness either upon the scale of the thermometer or the hygrometer, and the rate of evaporation.

In the climate of England the dew-point is seldom more than 30° below the temperature of the air, but in the Deccan, in India, with the temperature of the air at 90°, the dew-point has been seen at 29°,—making the degree of dryness 61° thermometric.

Professor Daniell states that "the more accurate mode of expressing the moisture of the air from an observation of the temperature and dew-point is by the quotient of the division of the elasticity of the vapors at the real atmospheric temperature, by the elasticity at the temperature of the dew-point; for, calling the term of saturation 1,000, as the elasticity of vapor at the temperature of the air is to the elasticity of vapor at the temperature of the dew-point, so is the term of saturation to the observed degree of moisture.

"Thus with regard to the observation in the Deccan — 1.430 : 0.194 : : 1000 : 135, — the fourth term is the degree of moisture on the hygrometric scale."

3. *d e* are two different forms of Mason's hygrometer. In this two thermometers are placed side by side, the bulb of one being covered with muslin or similar material, and wetted with water when an observation is to be made. The dimished temperature of the wet bulb, due to the evaporation of the moisture, is compared with the natural temperature of the other bulb; the temperature and the difference afford the data for determining the hygrometric conditions.

In *e* the bulb of one thermometer is kept constantly moist from a cistern fixed on the plate, to which the two are attached.

This is the most useful form of hygrometer. The theoretical relation between the indications of the two bulbs and the humidity of the air is rather complex and has given rise to much debate; it is usual to effect the reduction by tables which have been empirically constructed by comparison with the indications of the *dew-point* instrument of Daniell. The British tables for this purpose were constructed by Glaisher; edition of 1856 preferred. They are based upon a comparison of the simultaneous readings of the wet and dry bulb thermometers, and of Daniell's hygrometer, taken for a series of years in Greenwich Observatory, in Toronto, and in India. The ratio between the two readings is not equal at all degrees of temperature as marked on the dry bulb. When this temperature — the *natural*, it may be called — is 53° F. the *dew-point* is as much below the *wet bulb* as the latter is below 53° F., the temperature of the air. At higher temperatures the wet-bulb reading is nearer to the dew-point than to the air-temperature, and the reverse is the case at temperatures below 53° F. See PSYCHROMETER.

Two citations from "Cosmos" are not irrelevant: "In the brilliant period of the foundation of 'mathematical natural philosophy,' attempts to investigate the moisture of the atmosphere in its connection with variations of temperature and with the direction of the wind were not wanting. The Academia del Cimento conceived the happy idea of determining the quantity of vapor by evaporation and precipitation. The oldest Florentine hygrometer was accordingly an apparatus in which the quantity of precipitated water run off was determined by weight. To this condensation hygrometer, which, aided by the ideas of LeRoy, has gradually led in our own days to the exact psychrometric methods of Dalton, Daniell, and Auguste, there were added, according to the example previously set by Leonardo da Vinci, the absorption hygrometers, made of animal or vegetable substances, of Santorio (1625), Torricelli (1626), and Molyneux. Catgut and the beard of the wild oat were used almost at the same time. Instruments of this kind, founded on the absorption of the aqueous vapor contained in the atmosphere by organic substances, were provided with indexes and counterpoises, and were very similar in construction to Saussure's and Deluc's hair and whalebone hygrometers; but the instruments of the seventeenth century were deficient in the determination of fixed wet and dry points, so necessary for the comparison and understanding of the results. This desideratum was at last supplied by Regnault, but without reference to the variation which might be occasioned by time in the susceptibility of the hygrometic substances employed. Pictet, however, found that the hair of a Guanche mummy from Teneriffe, which might be a thousand years old, employed in a Saussure's hygrometer, still posseessed a satisfactory degree of sensibility."

"'The admiral' [Columbus], says Fernando Colon, ascribed the many refreshing falls of rain which cooled the air whilst he was sailing along the coast of Jamaica, to the extent and density of the forests which clothe the mountains. He takes this opportunity of remarking, in his ship's journal, that 'formerly there was much rain in Madeira, the Canaries, and the Azores; but since the trees which shaded the ground have been cut down, rain has become much more rare.' This warning has remained almost unheeded for more than three centuries and a half."

Hy'gro-met'ric Bal'ance. An instrument for indicating the relative density of the air, and consequent chances of rain or dry weather. It consists of a balance, from one arm of which is suspended a brass weight and from the other a large, thin, hollow cylinder. The two are arranged so as to be in equilibrium at a given density of the atmosphere, and it is evident that if the air become heavier, the large cylinder, displacing more air than the solid weight, will become more buoyant and ascend. If, on the contrary, the air become lighter, it will sink. A rod descending from the scale-beam serves to indicate, on the graduated arc below, the comparative density of the air at the time of making the observation.

If the air be heavy, fine weather may be expected; but if the cylinder sink, rain usually follows.

Hy'gro-scope. An instrument for indicating the degree of moisture of the atmosphere. See HYGROMETER; Deschanel's "Nat. Phil.," Part II., p. 367. See PSYCHROMETER.

Hy-pæ'thrum. (*Architecture.*) That portion of the interior of a building which is not protected by a roof. The ancient temples, which were entirely uncovered, were said to be hypæthral.

Digitized by Google

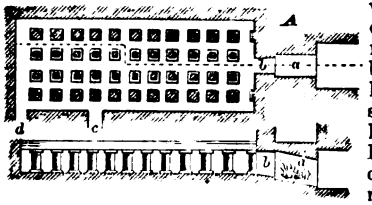
Hy'per-thy'rum; Hy'per-thy'non. (*Architecture.*) That part of the architrave which is over a door or window. See HEAD-MOLDING.

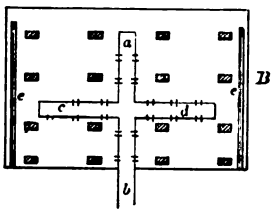
Hy'phen. A mark (-) for joining the parts of a compound word, or indicating a break in a single word at the end of a line.

Hy'po-caust. (*Building.*) A furnace for heating a building by hot air conducted under the floor and through the walls.

They were used by the Romans for heating their baths. One kind was constructed with flues running under the floor, and was heated from the outside of the building, and another was formed like a low chamber, its ceiling supported by small pillars or dwarf walls. This was immediately beneath the baths to be heated, and sometimes had flues leading to other apartments.

Fig. 2629.





Hypocausts.

Fig. 2629, *A*, is a plan and section of one discovered at Lincoln, England. This was 24½ feet long, 9½ feet wide, and 26 inches high in the clear. The ceiling, which formed the floor of the apartment above, was of large bricks laid in mortar, over which were tiles covered with stucco, the whole being about 10 inches thick. The products of combustion from the fire-chamber *a* passed through the arched opening *b* into the hypocaust, and were, it is supposed, discharged at *d*; *c* is believed to have been a flue leading to another apartment. The large fire space was necessary, as the Romans did not employ chimneys for increasing the draft.

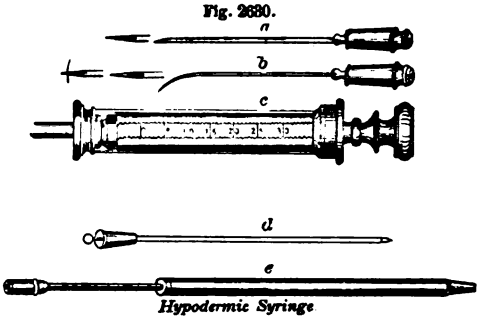
Hypocausts are in general use in Northern China, where the winters are severe. *B* illustrates their mode of construction. They are located beneath the floor of the house, and have two flues *a b*, *c d*, at right angles. These have a number of openings, which distribute the heat to all parts of the floor, which is paved with tiles or flagstones. *e e* are flues for carrying off smoke. The seats and sleeping-places are also heated by this arrangement. They are built of brick and are hollow, communicating with the hypocaust below. The fuel employed is composed of a mixture of fine coal, clay, earth, cow-dung, or refuse vegetable matter, formed into balls and dried. In houses of an inferior class, a sort of stove, built into one corner of the room, is used.

Hypocausts were in use by the emirs of Cordova, from the ninth to the thirteenth century, the heat being conveyed by caliducts to the winter apartments. See BATH; HEATING-APPARATUS.

Hy'po-der'mic Syr'inge. (*Surgical.*) An instrument for administering subcutaneous injections of solution of morphia, for the purpose of relieving pain. It consists of a syringe with graduated barrel or rod, and a canula of silver or steel which has a point for penetration and an opening for ejection of the liquid. The illustration *a b c* shows a form with a glass tube, a graduated rod, and detachable points of two shapes.

d e is a form of hypodermic syringe to be carried in a pocket-case. The point, inclosing the wire-

Fig. 2630.



Hypodermic Syringe

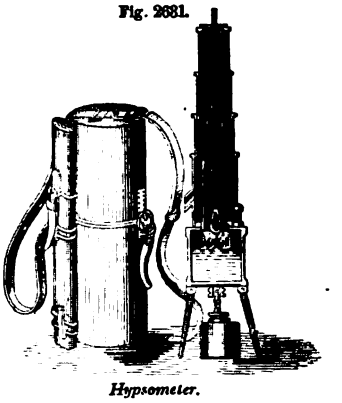
cleaner, fits into a hollow graduated piston. The barrel is an ordinary silver tube, the size of No. 10 catheter, and is six inches long. See also ACUPUNCTURATOR.

Hy'po-tra-che'li-um. (*Architecture.*) The necking of a column in the classical orders, consisting of several narrow cinctures cut into the shaft at the base of the echinus.

Hyp-som'e-ter. An instrument for measuring hights by observing differences in barometric pressures at different altitudes.

Notably, an instrument for determining altitudes by observation of the boiling-points of water. It has a water-vessel, lamp, and thermometer. The example shows the instrument and the case in which it is packed for transportation on the back of a tourist or attendant.

Fig. 2631.



Hypsometer.

Wollaston's apparatus for measuring hights by the temperature of boiling water has a mercurial thermometer with a very large bulb and a stem, which has a length of one inch for every degree of the scale. This is read by a vernier to thousandths. It is found that a difference of barometric pressure of 0.589 inches is equivalent to 1° in the boiling-point, or 530 feet of ascent at moderate elevations.

Tables have been constructed for use with the apparatus, showing the precise elevation corresponding to different temperatures of boiling water.

Hys'ter-om'e-ter. An instrument for ascertaining the size of the uterus.

Hys'ter'o-tome. (*Surgical.*) A knife for operations upon the womb; notably the Cæsarian section.

Digitized by Google

I.

Ice-an'chor. (*Nautical.*) A bent bar whose prong enters a hole in the ice; to the other end a mooring-hawser is bent.

Ice-ap-pli'an-ces. See: —

Ice-anchor.	Ice-hook.
Ice-apron.	Ice-house.
Ice-beam.	Ice-leveler.
Iceberg-alarm.	Ice-locomotive.
Ice-boat.	Ice-making.
Ice-box.	Ice-marker.
Ice-breaker.	Ice-pick.
Ice-calk:	Ice-pitcher.
Ice-carriage.	Ice-plane.
Ice-chain.	Ice-plow.
Ice-chest.	Ice-preserver.
Ice-chisel.	Ice-safe.
Ice-claw.	Ice-sandal.
Ice-cream freezer.	Ice-saw.
Ice-creeper.	Ice-scraper.
Ice-crusher.	Ice-shaver.
Ice-cutter.	Ice-spade.
Ice-cutting machine.	Ice-tongs.
Ice-elevator.	Ice-tools.

Ice-a'pron. (*Hydraulic Engineering.*) An ice-breaker or *starling* to protect the upper end of a bridge-pier. It presents an inclined edge up stream to break a field or cake of floating ice, or to sustain the pressure of a gorge of ice, and prevent the direct dislodging push of the ice upon the pier.

The ice-aprons of the Eads's St. Louis Railway Bridge are 200 feet long and 60 feet wide, and present an angle of 45° to the current. The frames are of squared oak timber, with three-inch oak planking and No. 16 sheet-iron skin.

Ice-beam. A guard-plank at a ship's bow to fend off ice.

Ice'berg-a-larm'. A thermometrical device to indicate the vicinity of icebergs by the cooling of the water, which is made to spring an alarm.

Ice-boat. 1. One employed for traveling on ice.

The *ice-boats* on the Maeze and Y, in Holland, consist of ordinary boats mounted on runners. The boat rests on transverse pieces, which are secured to a pair of parallel runners resembling those of skates. The extremities of the transverse pieces serve as outriggers, from which stays pass to the mast-heads of the craft to preserve the boat from being careened in its cradle when the sails are spread. The lower edge of the rudder is sharpened, to give it a sufficient adhesion to the ice to enable it to swerve the boat.

A boat can be made of a few planks, three skate-irons, a mast and sail, at a cost of a few dollars. The boat is V-shaped, composed of three planks, two forming the sides and one the base, which is the stern. Under each angle are skate-irons hung on pivots to allow swing. The craft is steered by the iron at the apex or bow. The rigging is usually sloop or yacht rig. These boats sail admirably, and may be numbered on the Hudson by scores; something over a hundred being owned by the various clubs and by private persons. Regattas take place on this river during the winter season when the condition of the ice and state of the wind invites. Attempts to utilize ice-boats for passenger and freight travel have not as yet been successful, owing to several uncertainties in themselves and their mode of going, the state of the ice, the state of the wind, and the probable condition of the cargo if the ice break.

2. A steamboat having a sharp and heavily strengthened prow and bow for forcing its way through ice in a harbor to keep a passage open for vessels. A favorite form of prow is a long ram, presenting an inclined edge to the ice, which is lifted by and broken across the sharp back of the ram.

Ice-box. A chest for domestic use for keeping cool provisions liable to spoil in warm weather.

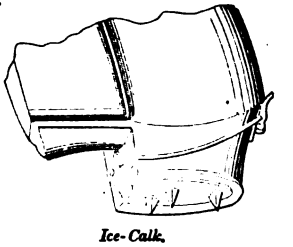
Ice-break'er. 1. *a.* A structure for the protection of bridge-piers, etc. It is of masonry or timber. In the Victoria Bridge across the St. Lawrence at Montreal it is a long, sloping ridge of stone presented up stream, and forming a wedge-shaped starling.

Other ice-breakers are starlings of *piles* or *cribs*. See ICE-APRON. See also PIVOT-BRIDGE.

b. A pier arranged with reference to the current, to prevent access of ice to the vessels in a harbor.

2. An *ice-breaker* for harbors is a steam-vessel provided with means for opening or keeping open a channel for ships.

Fig. 2632.

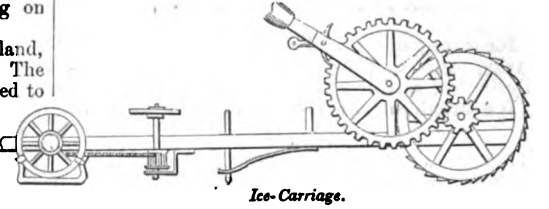


Ice-Calk.

Ice-calk. A spiked plate to be worn on the heel to keep the wearer from slipping on ice.

Ice-car'riage. A platform on runners, and with a means for propulsion on ice. The toothed wheel holds to the ice, and is turned by a small spur-wheel, which is engaged by a larger wheel actuated by a double-ended pawl lever. The brake consists of a pointed, vertically moving bar, which is ordinarily kept free from the ice by a spring.

Fig. 2633.



Ice-Carriage.

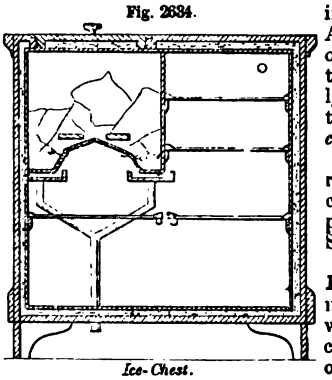
Ice-chair. A chair on runners to hold a lady who is pushed along by a skater in the rear.

Ice-chest. A form of domestic ice-chamber having apartments for the ice and the provisions, the food-chamber being cooled by air conducted to it from the ice-box or by the cold side of the latter, which forms a part of the inclosure of the food-chamber. In the example, the ice-box has an arched bottom and perforated depressions that connect with the drip-pans. A large refrigerating surface is thereby exposed to the air of the preserving chamber, and the temperature is reduced by contact of the drip.

Ice-chis'el. A socket chisel with a long handle, used in cutting holes in ice, either in Arctic explorations or as a starting-point for the saw in gather-

Digitized by Google

Fig. 2634.



Ice-Chest.

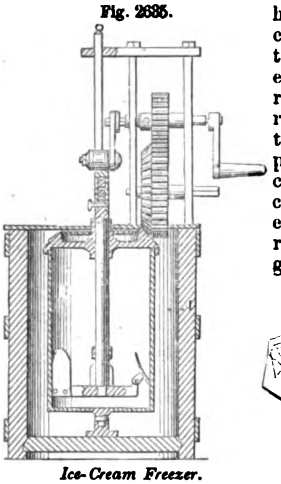
ing ice for use. Also for striking off blocks after they are partially detached by the cutter. See *c f*, Fig. 2658.

Ice-claw. A rope and pair of claws, for grappling ice-blocks. See *k*, Fig. 2658.

Ice-cream Freez'er. A machine in which cream, custard, or lemonade is stirred within a metallic vessel which is plunged in a tub of mingled broken ice and salt.

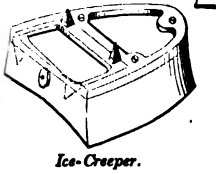
The dasher has vertical reciprocation by the play of a crank-pin in a horizontal slot of its cross-head. The vertical and pivoted scrapers have rotary and reciprocating motions respectively to clear the can sides. The paddles throw the cream outward. The can may be rotated or the dasher reciprocated singly, if desired.

Fig. 2635.



Ice-Cream Freezer.

Fig. 2636.

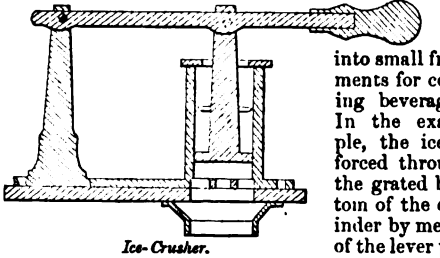


Ice-Creeper.

Ice-creep'er. A socket for the heel of a boot, having spurs to prevent slipping on ice. In the illustration, it is shown inverted.

Ice-crush'er. An implement for breaking ice into small fragments for cooling beverages. In the example, the ice is forced through the grated bottom of the cylinder by means of the lever piston.

Fig. 2637.



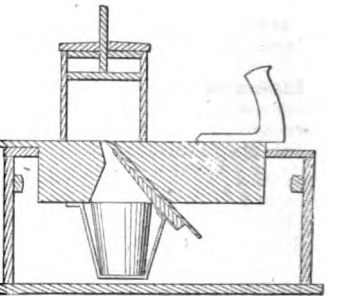
Ice-Crusher.

Ice-cut'ter. A plane for shaving ice for cooling beverages.

In the example, a reciprocating plane moves under a hopper in which is a block provided with a rod for pushing the ice against the plane. Under the hopper and below the plane is a spring for holding a tumbler into which the cut ice falls. See also ICE-PLANE.

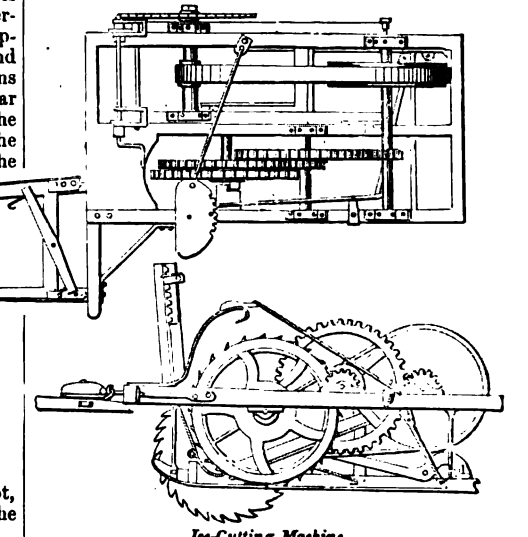
Ice-cut'ting Machine'. One for cutting kerfs in pond ice, to reduce the surface to strips which are afterwards broken into blocks by the axe or spade. In the example, it is a circular saw on a sled, which is drawn by a horse. The saw receives motion from a serrated wheel which engages the ice, and is vertically adjustable by a rack and pinion operating its journal-frame. See also *b*, Fig. 2658.

Fig. 2638.



Ice-Cutter.

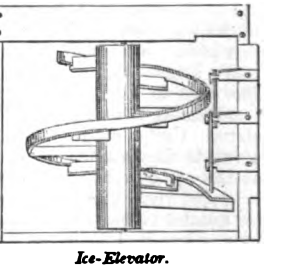
Fig. 2639.



Ice-Cutting Machine.

Ice-el'e-va-tor. A machine for lifting block-ice from one level to another, as from the pond level to the ice-house; in the ice-house from one level to another, and so forth. There are several kinds. In one, the ice is pushed up a spiral incline by the arms projecting radially from a vertical rotating central post.

Fig. 2640.



Ice-Elevator.

Fig. 2641 is another form, in which an endless chain has a series of hooks *R* which grab the blocks of ice and draw them up the incline *G E*. This is made in sections hinged together, so as to permit either of the upper sections to be placed at different angles to discharge the ice at different elevations. The frame supporting the driving-wheel of the endless chain has a

Digitized by Google

spring bar which sets the hooks in a position to engage with the cakes of ice.

Ice-hook. A hook used in landing ice and transporting it on ways to a house or hold. See *g*, Fig. 2658.

Ice-house. Plutarch records that the snow, collected on the mountains during the winter months, was preserved during the summer in deep pits covered with coarse cloths and with chaff. Water cooled with snow was considered a great luxury. Theocritus calls it an ambrosial drink, but Aristotle seems to have doubted its healthfulness. Solomon refers to its use in Prov. xxv. 13: "As the cold of snow in the time of harvest, so is a faithful messenger to them that send him; for he refresheth the soul of his master."

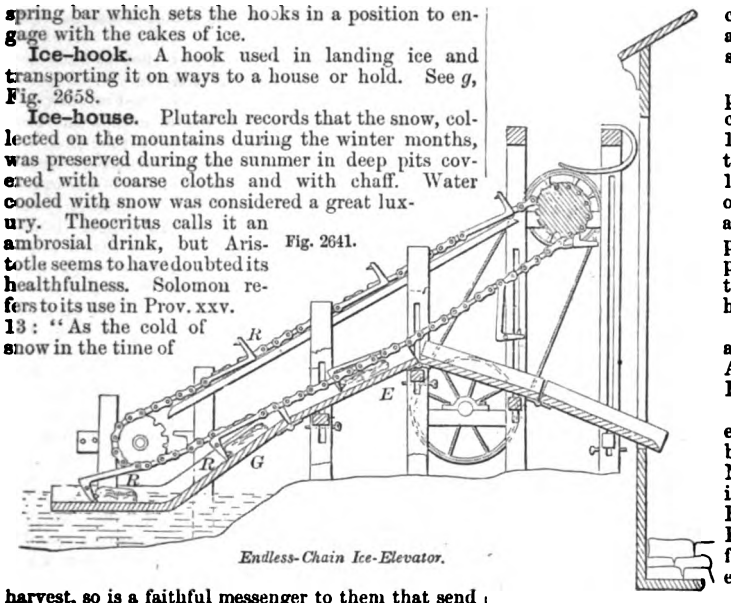


Fig. 2641. *Endless-Chain Ice-Elevator.*

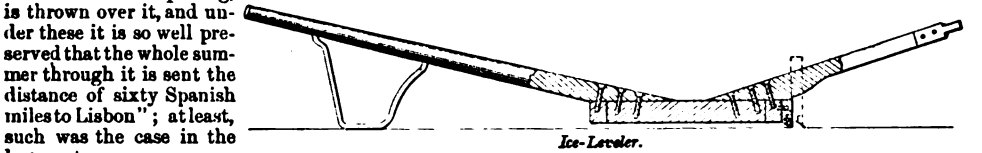
When Alexander the Great besieged Patra, he caused thirty trenches to be dug and filled with snow, which was covered with oak branches, and kept a long time.

In Portugal, "snow is collected in a deep gulley, and grass or green sods, covered with sheep-dung, is thrown over it, and under these it is so well preserved that the whole summer through it is sent the distance of sixty Spanish miles to Lisbon"; at least, such was the case in the last century.

In Southern Europe and Asia Minor it may be observed that snow is, and always has been, used instead of ice, being more easily attainable from the summits of the mountains, while ice must be either imported or made artificially. The Appenines, the Sierra Nevada, and other mountains of South Europe, yield an inexhaustible supply in winter in regions where snow seldom or never falls on the plains below, and a very slight protection from the heats of summer suffices to preserve it at considerable elevations above the sea, where the thermometer never ranges very high.

Fig. 2642.



Ice-House.

At least one natural ice-house has been discovered on Mount Etna, where a vast deposit of snow, covered by a mass of ashes and lava, has been preserved for untold ages.

The highest natural temperature authentically recorded was at Bagdad, in 1819, when the themometer in the shade indicated 120° Fah. On the west coast of Africa the heat is nearly as great. The men employed in the English expedition to Abyssinia think that Aden is the hottest hole on earth.

Burckhardt, in Egypt, and Humboldt, in South America, observed 117° Fah. in the shade.

About −70° is the lowest temperature observed by our Arctic navigators. Natterer, a German chemist, obtained −220° Fah. Faraday obtained −166° Fah. Neither succeeded in freezing pure alcohol or ether.

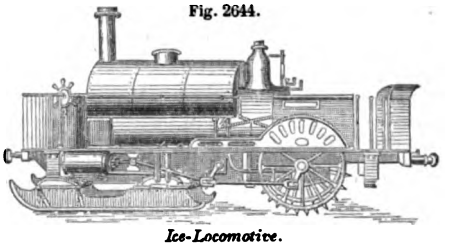
Fig. 2642 is a sectional view of an ice-house for brewers and butchers. It has an ice-chamber *B* and cooling-vault *A*, provided with one or more ventilators *I*.

Ice-lev'el-er. An implement for leveling the surface of pond ice. It has an oblong frame, upon the front side of which is affixed a cutting-edge of steel. From the forward end a tongue projects, and from the rear a guiding-pole with a bent knee, composed of a metallic rod that runs upon the ice. A wide board is adjusted to the front side of the frame for removing snow.

Ice-Leveler.

Ice-lo-co-mo'tive. A traction engine for running on ice; one constructed by Messrs. Neilson of Glasgow, and employed for conveying passengers and freight between St. Petersburg and Cronstadt, has two driving-wheels five feet in diameter and studded with spikes. The front part rests on a sledge, which is swiveled and may be turned by the wheel, which has an endless screw working a pinion that turns a segment rack attached to the sled-body. The cylinders are 10 inches in diameter and

Fig. 2644.



Ice-Locomotive.

Digitized by Google

22 inches stroke. The weight of the engine is 12 tons, and it attains a speed of 18 miles an hour.

Ice-mak'ing. Evaporation, radiation, liquefaction, and sudden reduction of pressure, are the causes by which the temperature of a body may be depressed.

Class 1. Vaporization.

This includes those processes which depend upon the vaporization of water, ether, ammonia, benzole, etc., which, in assuming the vaporous form, change sensible heat to latent, extracting it from the objects most convenient thereto, — in this case a reservoir of water whose contents are thereby congealed.

In this class are the atomizers or spray apparatus.

One form of this machine is founded upon the old practice in Hindostan, of cooling water by the evaporation from the outer surface of porous vessels through which the contents percolate. A part is thus sacrificed in cooling the remainder, the water in its evaporation rendering latent the heat abstracted from the contents of the jar. The extent to which this process is carried determines whether the water is cooled to the freezing-point or not.

A modification of this device is found in wrapping a non-porous jar or other vessel with a bibulous covering, which is kept wet and subjected to a draft of air. The contents of the vessel part with their sensible heat in furnishing the heat required by the evaporation of the water in the envelope.

"Protagorus, relating the voyage of King Antiochus down the river Nile, says: 'They expose the water in large earthen ewers on the top of the house, and two slaves are kept sprinkling the vessels with water the whole night; and at daybreak they bring them down and immerse the ewers in water, which is used without snow, as it is cool enough.'" — *Deipnosophists.*

The opinion prevailed among the ancients that water previously boiled or heated was more readily cooled, and in Egypt and other warm countries earthen vessels filled with boiled or heated water were exposed to the air during the night, and in the morning placed in a pit or cellar and bound around with fresh or green plants which were moistened with water, and preserved their contents cool throughout the whole day. In the countries of Southern Asia a similar opinion and practice still prevails.

So far, the conditions of evaporation have been the exposure of water in an atmosphere not saturated with moisture and preferably to air in motion. It may also be added that an artificial motion by fans may be made to replace the lack of natural motion by wind or draft. This accelerates the operation as bringing a larger amount of air in contact with the evaporative surface, and also brushing away the saturated atmosphere immediately adjacent.

Under a pressure less than that of the atmosphere, vaporization takes place at a lower temperature. Were two thirds of the atmospheric pressure removed, water would boil at ordinary summer heat. A vessel of water placed under the receiver of an air-pump, which is then exhausted of air, speedily enters into ebullition; but, unless the machine is kept constantly in action, the vapor which is thus formed will restore very promptly the pressure upon the surface which has been removed by the exhaustion. If, however, the pump be powerful enough to carry off the vapor as fast as it is formed, and be steadily worked, the heat which the rising vapor withdraws from the water will presently reduce the temperature to the freezing-point, and the liquid will be converted into ice.

In 1755, Dr. Cullen discovered that removing the pressure of air facilitated evaporation to a degree which enabled him to freeze water even in summer.

In 1777, Mr. Nairne discovered that introducing sulphuric acid into an exhausted receiver absorbed an aqueous vapor from and thereby dried rarefied air; and by an arrangement on these principles, in 1810, by which he got rid of the vapor that rose from the water, he prevented its forming a permanent atmosphere, so as to prevent the continuance of the operation. Professor Leslie succeeded in freezing quantities of water from 1 to 1½ pounds in weight, though he could not effect the congelation of much larger quantities. This method of promoting evaporation John Vallance, in 1824, improved by removing the atmospheric pressure, which enabled him to carry off the vapor from large surfaces of water and consequently freeze large quantities of ice.

The Parisian restaurants have decanters (*carafes frappées*) filled with water frozen by placing them in shallow tanks of sea-water, each of which is provided with a copper reservoir connected with a receiver filled with ether. The air is exhausted from the reservoirs by an air-pump worked by steam, vaporizing the ether and reducing the temperature of the sea-water and that in the decanters below the freezing-point. The water in the decanters usually remains liquid until stirred with a glass rod, when it immediately congeals.

Edmond Carré's sulphuric-acid freezing-apparatus is upon this principle (shown at 1, Plate XXVI.), and is used to produce the *carafes frappées* (frozen decanters) so frequently seen in Paris. It consists of a large vessel, resembling the boiler of a steam-engine, which is designed to contain the concentrated sulphuric acid; of an air-pump with tube connections to be adapted to the wide mouths of the *carafes*, and of a mechanism by which the lever of the air-pump is made to keep the acid in continual agitation. The great volume of the acid renders the loss of absorptive power by dilution very slow, and the constant agitation prevents the formation of a superficial dilute stratum, which would interfere materially with the success.

In the drawing, *a* is the reservoir of sulphuric acid; *f*, a *carafe* of water connected by the tube *r* with the apparatus, and having a stop-cock at *l*. *p* is the barrel of the pump and *h* its lever, which also agitates the oscillator, shown in dotted lines.

We have considered in regular sequence the cooling of water by the access of air under natural conditions; the acceleration of the operation by artificial draft; the facilitating of the operation by the lessening of the atmospheric pressure; the absorption of the evolved vapor by sulphuric acid. We have now to consider the use of materials more volatile than water, notably ether and ammonia, but common alcohol, ether, methylic ether or alcohol, sulphurous or carbonic acid, bisulphide of carbon, gasoline, etc., have each been used.

Liquids.	Boiling-Point Fah.	Latent Heat of Vapor.	Tension of Vapor.
Water	212	966.6	0.623
Alcohol	173.5	376	1.60
Methylic alcohol . .	119.7	475	1.11
Ether . . .	98	164.4	2.58

In Ferdinand Carré's apparatus the efficient cause producing cold is evaporation, but the liquid employed is ammonia, a substance which is not only much more volatile than water, but, under ordinary atmospheric pressure, is indeed permanently gaseous. Gaseous ammonia is liquefied by a pressure of 8½ atmospheres at a temperature of 68° Fah., or of 10 atmospheres at 77°, the pressure required rising very

Digitized by Google

rapidly with the temperature. To liquefy it by cold requires a very low temperature (−65.5 Cent.), and as its latent heat is great it would become a valuable agent for the purpose of producing cold if its vapor could be removed. To do this with economy it must be saved and recondensed. This may be done mechanically by a pump, but with much greater advantage by water, which has the property of absorbing ammoniacal gas in great volume and with singular rapidity. This fact was first illustrated by Faraday in 1823. He used a bent glass tube, containing at one end a portion of chloride of silver saturated with ammonia at 60° Fah. or lower, and hermetically sealed after the air had been expelled by slightly warming the compound. If the chloride be heated to 100° Fah., the ammonia expelled, and the other end of the tube plunged in a cold bath, the gas becomes liquefied. If now the end containing the compound be plunged in a refrigeratory and the other in water, the liquid ammonia will commence boiling, the chloride will reabsorb the vapor as fast as produced, and by the rapid evaporation the water around the tube will be converted into ice.

For economic reasons (see Professor Barnard's Report on the French Exposition, page 369) water is to be preferred to chloride of silver. Water absorbs at moderate temperature 700 times its own volume of ammoniacal gas, a volume capable of producing a quantity of liquid ammonia equal to two thirds the bulk and one half the weight of its own volume, and capable of converting into ice more than three times its own bulk. On the contrary, a given quantity of chloride of silver will produce only a thirtieth part of its bulk of liquid ammonia, and a fifth part of its bulk of ice at 32° Fah.

F. Carré's intermittent apparatus (2, Plate XXVI.) is similar in its operation to the Faraday experiment, aq. amm. being substituted for the Ag., Cl. + ammonia. In the engraving, *k* is the boiler containing the liquor ammonia, and connecting by the pipe *r r* with the refrigerator *t*, which has a well in which is a pan containing the water *z* to be frozen. The boiler *k* is placed over a portable furnace, and the apparatus purged of air, which is driven by the evolved gas out at the stop-cock *m*. This being closed, and the refrigerator immersed in a tank of cool water, the temperature of the aqua ammonia is raised to 130° or 140° Cent., at which heat the ammonia is expelled and is condensed in a liquid form in the refrigerator *t*. The boiler *k* being now removed from the furnace and placed in the water-bath, the temperature of the water in the boiler will fall and the power of the water to dissolve ammonia will be restored. The gas will be rapidly re-dissolved, reducing the pressure, as the liquid ammonia will evaporate with corresponding rapidity, drawing for its latent heat upon the sensible heat of the water to be frozen. The result will be the complete evaporation of the liquefied ammonia and the restoration of an aqueous solution, in the boiler, of the original strength. Between the ice-pan and the well is a body of alcohol which will not freeze, but will act as a conductor. During the refrigerating, the vessel *t* has a non-conducting envelope.

Ferd. Carré's continuous process (3, Plate XXVI.), like the intermittent of Edmond Carré, depends also for its efficacy upon the evaporation of liquid ammonia. In each process the liquefaction is effected in substantially the same way. Aqua ammonia is introduced into a boiler, and the gas is expelled by heat into a condenser; but in order that the process may not be arrested by the exhaustion of the solution, the impoverished liquid is gradually withdrawn from the bottom of the boiler, while a corresponding volume of a fresh and strong solution is constantly flowing in at the top. The condensation is produced by the united effect of cold and pressure. From the condenser, the ammonia in a liquid state passes on to a refrigerator, in which are placed vessels containing the water to be frozen; and as the boiler and the condenser keep up an unfailing supply of the liquid, so the refrigerator will continue to freeze successive masses, so long as the proper temperature is maintained in the boiler. The ammoniacal vapor which leaves the refrigerator is re-dissolved to form the rich solution which is to supply the boiler; and the water of solution is the same which was previously withdrawn exhausted from the boiler itself. Thus, as there is nothing added to the contents of the apparatus, and as there is no escape of any part of them by leakage or otherwise, the same materials go on indefinitely producing a uniform effect.

a is the boiler, exposed to the heat of the furnace *b*; *c* is an indicator to show the level of the liquid; *i* is a tube conducting gas to the liquefier *j*; the vertical pipe above the branch *i* leads to a safety-valve, and any escaping gas passes by pipe *e* to the water-tank *e'*, where it is absorbed. *f* is a tube which brings back to the boiler saturated solution of ammonia from the absorbing apparatus *u u*; this solution passes downward, trickling through the perforated trays *g*, while the ascending gas rises in a sinuous course alternately around the edge of one tray and through a central hole in the next, and so on. This condenses and carries back the watery vapor which accompanies the gas.

The gas passes by tube *i* to the liquefier *j*, passing through a box *k* and a congeries of zigzag and spiral tubes in a bath of cold water constantly renewed from reservoir *z*, which also supplies other parts of the apparatus. The congeries of tubes terminates in another box *k'*, and the ammonia is by this time in a liquid state under the pressure of 10 atmospheres, which is constantly maintained in the boiler. In the liquid state the ammonia passes by the pipe *l* to the efflux regulator *m*, which is the dividing barrier between the part of the machine in which a regular pressure of 10 atmospheres is maintained and the following part where the pressure does not exceed 1½ atmospheres. The regulating device is a floating cup which opens or closes a hole of influx.

The liquid passes from the regulator *m* by pipe *n* to the distributor *p*, the pipe *n* being wound spirally around the tube *t*, through which the vaporized ammonia is returning from the refrigerator *q q*; the vapors serving to reduce the temperature of the liquid in *n* before it reaches the refrigerator.

The refrigerator itself consists of a number of zigzag or spiral tubes — in the apparatus here represented, six in all — immersed in a tank constructed of non-conducting substances. These zigzags return upon themselves six times, forming so many partitions in the tank, between which vessels containing the substances to be subjected to cold may be placed. Each one of the six zigzags receives an equal supply of the liquid ammonia from the distributor. The small tubes conveying this supply are shown at *p*. The vessels *r* to be refrigerated are sustained on a carriage, which is slid back and forth by the same power that works the pump *g'* by which the re-saturated solution of ammonia is returned to the boiler. The space in the tank surrounding the zigzags and the water-vessels *r* is filled with an uncongealable liquid, such as alcohol or a solution of chloride of calcium. The ammonia in the zigzags *q* discharges in a vaporized form into the *collector s* and passes through the tube *t* to the cylinder *u*, where it extends nearly to the bottom of the vessel, and there

Digitized by Google

discharges the gas into the water which has been brought from the bottom of the boiler *a*, and partially fills the cylinder *u*. From this water the ammonia has been nearly exhausted, and it therefore greedily absorbs the gas ejected into it by pipe *t*. On the left of vessel *u* is a water-level indicator.

Within the vessel *u* is a worm which receives water by pipe *a'* from the elevated reservoir *z*; after passing to the bottom of the spiral the pipe curves upward and then (marked *b*) descends nearly to the bottom of the vessel *y*, where it discharges.

The water from the boiler *a* passes by pipes *w w* to the coolers *x y* before reaching the vessel *u*, where it re-absorbs ammonia. Between the boiler *a* and the vessel *u* the water is cooled so as to fit it for absorbing gas more freely. The pressure in the boiler is sufficient to expel it when the stop-cock *w* is opened. The vessel *x* is formed of two concentric cylinders, between which are two spiral tubes formed of the pipe *w* continued, and these spirals are immersed in a liquid which fills the annular space between the cylinders and is the reconstituted ammoniacal solution on its way from the absorber *u* to the boiler *a*. The water from the boiler is hot and that from the absorber is cold, and the two to some extent exchange temperatures to mutual advantage, and with additional effect in that they circulate in opposite directions, the liquid from the absorber entering at the bottom and ascending, while the heated water from the boiler enters at the top and descends. From *x* the water in the spiral is conveyed in the pipe *w*, still continued in a single spiral ascending in the vessel *y*, and continued farther in a pipe *w* alongside of the absorber *u*, into which it discharges into a sieve *v* and from which it descends in a shower.

The exhausted solution from the boiler *a* flows freely, as has been said, from the boiler, by pipe *w*, to the absorber *u*, passing the coolers *x y* as described, but it requires some power to force the reconstituted solution back from the absorber *u* through the pipe *f* to the boiler. This power is a pump *g* driven by a steam-engine or other motor, and taking the saturated solution from the absorber by pipe *h'* and discharging it by pipe *i'* into the vessel *x*, from whence it passes by pipe *f* to the dome above the boiler, as described some distance above. Gas finding its way into the pump is discharged into the upper part of *u*. *e''* is a pipe leading to the enveloping tube *o*, from whence water is conducted by *f'* for the use of the ice-vessels *r*. As the water passes through *o* it is cooled by the ascending vapors of ammonia.

In starting the machine, it is first blown through to expel the air. The air escaping from the vessel *u* passes by pipe *c* to the purger *d* and passes beneath the surface of the water therein, which retains any escaping ammonia.

This apparatus requires a large amount of refrigerating water to maintain at the desired temperature the liquefier and the absorbent vessel, and it also involves a consumption of fuel, not only to heat the boiler containing the ammoniacal solution, but also to work the forcing-pump. The pump may be worked by water-power, if such a power is obtainable, or even in small models by hand; but for an apparatus producing more than one hundred pounds of ice per hour, a motor is indispensable.

It is stated by Mr. Carré that for every pound of coal burned there are produced from eight to twelve pounds of ice, according to the dimensions of the apparatus. To manage the larger forms of the apparatus, the services of two men are required, and a motor also is necessary, capable of driving two hundred and twenty gallons of liquid per hour into the boiler. The pressure in the boiler must be taken, for the purposes of computation, at not less than ten atmospheres; and as the machines are adequate to the production of five hundred pounds per hour of ice, they will, within the same time, liberate from solution, liquefy, evaporate, and re-dissolve one hundred pounds of pure ammonia.

On the evaporating principle are the water-jars, or *monkeys*, used in tropical countries and the east of Europe. These are merely unglazed earthenware jugs having a small neck and a spout, and suspended in a current of air or in a doorway. The Australian device for the same purpose is a bucket of canvas, nearly waterproof, and having a flannel cover to form a sieve, and a spout below to draw off the water. Evaporation proceeds rapidly from the wet surface. The East Indian *tatta* (Hind. *tattah*, a screen) is a curtain of bamboo placed in front of a window or doorway and kept wet by a trickling stream of water so as to cool the air passing through its meshes into the apartment.

Fig 2645.

Hindoo Gurgiet.

The mode of procuring ice by exposure in shallow, porous vessels, laid on straw and exposed to the night air, is stated to be practiced in India. The small crust of ice is carefully removed and stored in a straw-lined pit, before sunrise. A large plain, unobstructed as much as possible by trees or buildings, is selected for the purpose, in which pits or excavations twenty or thirty feet square and two feet deep are sunk, the floors being covered with dry stalks of corn or sugar-cane. Upon these are placed the water-vessels, constructed of porous earthenware, and not much more than an inch deep. In the morning, if the sky has been clear, the vessels are found to contain thin plates of ice, which are carefully gathered and stored away. This process was successfully imitated in England in the latter part of the last century by Dr. Wells, author of the Essay on Dew; and soon afterward an attempt was made in France to employ it for the systematic manufacture of ice, but the undertaking proved to be economically a failure.

Many of the modern ice-machines depend upon the conversion of sensible heat into latent by evaporation, liquids which vaporize at low temperatures being selected.

Harrison's Australian machine used ether evaporating into a partial vacuum produced by an air-pump, and instead of acting directly upon the water to be frozen it was made to reduce the temperature of a solution of salt, which does not congeal at the freezing-point of water, and the solution, thus made extremely cold, was then made to pass between cases containing the water, and, by reducing the temperature, secured the requisite congelation of the same. Twining's patent of 1862 is of this class.

Next in sequence may be considered a French invention, in which the freezing agent employed was amylic ether, which is capable of being dissolved by sulphuric acid. The ether being expelled from the acid by heat, under a pressure of several atmospheres, was liquefied, and passed in this condition to a suitable reservoir, from which, by turning a valve or stop-cock, it was allowed to expand and pass through spiral ducts arranged around a cylinder containing the water to be congealed; the expansion of the fluid to a gaseous condition acting, as in the other ether machines, to abstract the heat from the water and freeze the same. After having thus accomplished its work, the ether passed to vessels of sulphuric

Digitized by Google

acid by which it was absorbed, to be expelled therefrom by heat on a repetition of the process.

Twining's apparatus, patented in the United States, November 8, 1853, and subsequently extended for seven years, embraces an exhaust vessel, a pump, and a condensing vessel or "restorer." The water to be frozen is placed in chambers enclosed between thin metallic pipes, plates, or partitions, through which the vapor of a volatile liquid, as ether, sulphide of carbon, etc., is drawn by an air-pump. The vapor is condensed in a coil of pipe surrounded by cold water, and is returned to the reservoir from whence the liquid originally came. Four different modes of applying this principle, substantially the same but varying in details, are specified in the patent.

In Siebe's apparatus an air-pump is employed to vaporize the ether, the vapor of which is then conveyed into the refrigerator, which is surrounded with strong brine. The water to be made into ice is put in metallic troughs, and the brine surrounding them is, by means of the exhaustive process above referred to, cooled down to from 10° to 18° Fah., freezing the water to a depth determined by the time it is subjected to the process.

In Van der Weyde's machine are employed an exhaust and force pump, a cooling coil, and two refrigerators, which act as reservoirs for the condensed liquid. Naphtha, gasoline, rhigoline, or chimogene, are preferred. These are evaporated by an air-pump and forced through a freezer, in which are vessels containing water, surrounded by enclosing vessels filled with glycerine, the outside being surrounded by cryogene. The evaporation of the cryogene causes the refrigeration of the water to a sufficient extent to crystallize it; that is, form it into ice.

Reece's apparatus operates substantially on the Carré principle. The ammoniacal gas employed passes under considerable tension from the refrigerator into a cylinder having a slide valve, entry and exhaust ports, similar to those of a high-pressure engine, so that the gas is utilized to drive the pumps of the apparatus. From the cylinder it passes to the absorber and is returned to the reservoir.

Seely employs anhydrous ammonia. The generators are filled, or partially so, with dry, pulverized chloride of calcium. One of the generators is heated by steam coils, the generated gas passing through the condenser, evaporating in the refrigerator, and is finally absorbed by the dry chloride in the other receiver, to which heat is then applied in its turn, the other reservoir now becoming the condenser.

In Johnston and Whitelaw's, the liquid, bisulphide of carbon, after being vaporized is, with the air forced in by the air-pump, conducted through chambers containing oil, which absorbs the greater part of the moisture of the gas, the moisture of the air being taken up by chloride of calcium, in a pipe leading to the air-pump. The freezing arrangements are similar to those generally employed in machines of this class.

In Charles Tellier's machine, the liquid employed is methylic ether in a volatile state, not requiring to be subjected to heat. It comprises a congealer, compressing-pump, condensing-coil, and reservoir. The congealer consists of five or more receivers of a flat form connected by tubes. The apparatus is placed in a tank containing the water to be congealed. The fluid from the reservoir passes to the congealer, and the vapor exhausted therefrom by the air-pump is conveyed back to the reservoir through a worm.

The novelty of this apparatus consists in freezing the water by immediate contact with metallic plates forming a closed chamber.

For use on shipboard, the congealer is provided with four outlets terminating in a trap. Late attempts at transportation, on shipboard, of fresh meat in ice, from Australia, Buenos Ayres, and Texas to European and United States ports, have given a fillip to this class of machinery.

2. *Radiation.* This does not affect the subject from a mechanical point of view, and we therefore dismiss it.

Class 3. Liquefaction.

Machines and apparatus for icing cream, custard, lemonade, etc., may be classed under this head, and generally operate by means of a frigorific composition of pounded ice and chloride of sodium, in a vessel which surrounds the chamber in which the article to be frozen is placed. The tub containing the ice and salt is of wood, a poor conductor of caloric; and as the ice in liquefaction converts a large quantity of sensible heat into latent, the heat of the cream is carried off to supply the demand of the melting ice, and the cream becomes frozen. When ice or snow is not available, the combination of certain chemicals may produce the same result. The cream is stirred to constantly expose fresh material to the sides of the vessel exposed to the cooling compound. See tables below. See also ICE-CREAM FREEZER.

The use of saltpeter for cooling liquids was known at a remote period in India. It was probably used anciently as it was, in more modern times, in Rome. "The wine to be cooled was put in a long-necked bottle, which was immersed in another vessel filled with cold water; saltpeter was then gradually thrown into the water, and while it was dissolving a quick rotary motion was imparted to the bottle."

Freezing water by a mixture of snow or ice and saltpeter is first mentioned by Tancredus, a physician of Naples, 1607, who says that, by means of it, a tumbler of water may be converted into a block of solid ice. Santorio, in 1626, speaks of freezing wine by a mixture of snow and common salt.

Orosius (King Alfred's version), about A. D. 400, wrote: "And there is among the Esthonians a tribe that can produce cold, and therefore the dead in whom they produce that cold lie so long there and do not putrefy; and if any one sets two vessels full of ale or water, they contrive that one shall be frozen, be it summer or be it winter."

By the evaporation of a mixture of solid carbonic acid and sulphuric ether a temperature of 166 degrees below the freezing-point has been produced. By means of this intense cold, assisted by mechanical pressure, several of the gaseous bodies have been condensed into liquids and in some instances solidified.

Class 4. Reduction of pressure.

Machines in which the absorption of heat from the water is accomplished by the expansion of air or gas, or of a liquid into a gaseous condition.

In this division are one class, the carbonic-acid, ether, and ammonia engines, those materials being used as a convenient fluid for the purpose.

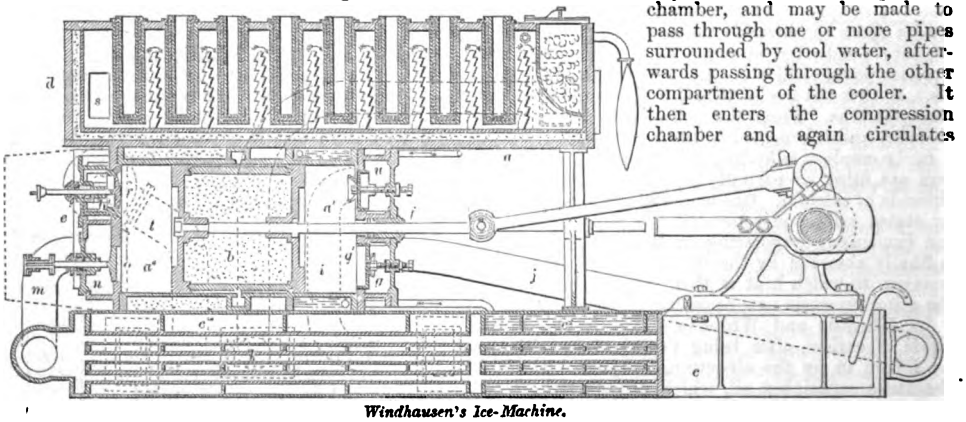
The effect of the rapid dilatation of fluids under a sudden reduction of pressure is strikingly illustrated in the hydraulic machine of Chemnitz, Hungary (see page 28), in which air is highly compressed in a closed reservoir under a column of water. If a stop-cock in this reservoir be suddenly opened, the expanding air rushing out produces a degree of cold sufficient to freeze the drops of water which it brings with it into pellets of ice.

Machines acting by expansion of air-envelope.

Kirk's apparatus (English) was of this character; that is, it absorbed heat by the expansion of air when liberated after compression by suitable mechanical means, the expansion of the air rendering latent the heat in the same manner as the expansion or vaporization of the ether or equivalent fluids in the cases hereinbefore described.

Windhausen's machine has one or two double-acting cylinders with pistons. In case a single cylinder is employed, the air is condensed on one side of the piston and expanded on the other. When two cylinders are used one serves as a condenser and the other serves to expand the air. From the condensing chamber the air passes into a cooler having two compartments, in one of which it is cooled by air and in the other by a constant flow of cool water. From the cooler it passes into the expansion chamber, whence it escapes through a temperature regulator into the refrigerator, in which the vessels containing the water are placed. By means of this regulator a portion of the air from the expansion chamber may be admitted to one compartment of the cooler for the purpose of reducing its temperature. When the air in the refrigerator has become too much heated to be of farther service there, though still at a low temperature, it passes through this compartment of the cooler on its way back to the compression chamber, and may be made to pass through one or more pipes surrounded by cool water, afterwards passing through the other compartment of the cooler. It then enters the compression chamber and again circulates through the apparatus as before. The operation is thus rendered continuous.

Fig. 2646.



Windhausen's Ice-Machine.

The machine is provided with suitable valves and connections, and may be operated by hand or power.

The operation is as follows: —

During the forward stroke of the piston — that is to say, its movement toward the front cylinder head *f* — the air is compressed in the compressing-chamber *a'*, and by its pressure caused to open the valve and pass out through the compartment *g* of the head and through the pipe *j* to the cooler, in which it passes first through the pipes *c'*, and afterward through the pipes *c''*, and is thereby cooled. From the cooler the compressed air passes through the pipe *m* into the compartment *n* of the back cylinder-head *e*, whence it passes through the valve *o* into the expansion-chamber *a''* of the cylinder during a portion of the stroke, and until the valve *o* is closed, after which the air in the latter chamber expands during the remainder of the stroke. During the whole return or back-stroke of the piston, the expanded and cooled air from the expansion-chamber passes out through the open valve *r* into compartment *b'* of the cylinder-head *e*, and thence to the temperature-regulator, whence a portion of it passes through the pipe *s* to the refrigerator, and a portion through the pipe *t* into the space surrounding the pipes *c''* in the left compartment of the cooler. At the same time the air displaced from the refrigerator by the incoming cold air passes out through the pipe *k* into the aforesaid space of the cooler. The air all passes out from this space of the cooler, through the pipe *i*, into the compartment *u* of the front cylinder-head, whence it is drawn by the

Digitized by Google

piston, through the inlet-valve into the compression-chamber of the cylinder.

The refrigerator *d* consists of a double-cased rectangular wooden chamber, the space between the casings being filled with loose cotton or other non-conductor of heat. Its cover has rectangular openings for the insertion of metallic cases for containing the vessels in which the water to be frozen is placed. To insure the air coming fully in contact with all parts of the cases, zigzag partitions are placed in the compartments between them. The air in the refrigerator, expanded to atmospheric pressure, abstracts heat from the metallic cases, becoming gradually warmed itself, and is finally, through a pipe *k*, returned to the cooler. A uniform pressure is maintained within the refrigerator by means of an india-rubber bag, which admits or gives out air, according as the pressure is in excess of or below that of the atmosphere.

In Gorrie's apparatus, air is compressed by a double-acting pump into which water is injected on that side of the piston on which condensation is taking place. The condensed air passes through a worm surrounded by cold water to a reservoir, whence it is admitted to an auxiliary pump driven by the expansion of the compressed air, in which it is expanded, cooling a non-congealable fluid in a jacket surrounding the pump-cylinder. This abstracts the heat from the water contained in a reservoir in a chamber above the pump, causing its congelation.

Lowe uses carbonic-acid gas compressed into a liquid state. The apparatus consists of a gas-holder, a pump, a cooler, a dryer filled with chloride of calcium, a condensing coil placed in a tank and surrounded by water, and an expansion or congealing chamber in which are placed the receptacles containing the water to be frozen. The gas is admitted to the pump, where it is liquefied. The heat thus generated is absorbed by the cooler, and the gas is allowed to expand into the refrigerator, where it performs the office of freezing the water.

Tuttle and Lugo. In this apparatus air is compressed and forced by a pump into a tubular chamber, the tubes of which are surrounded by cold water, and thence through a second chamber, the tubes of which are surrounded by a volatile liquid. It next passes into the refrigerating chamber, rising through a volatile liquid as ether, bisulphide of carbon, etc., contained therein; the air and vapor from the liquid fill the interior of this chamber, surrounding the vessels in which the water is contained and congealing it. They are thence conducted through a cooling chamber back to the pump.

A pipe is provided by which the compressed air may be carried directly to the refrigerator.

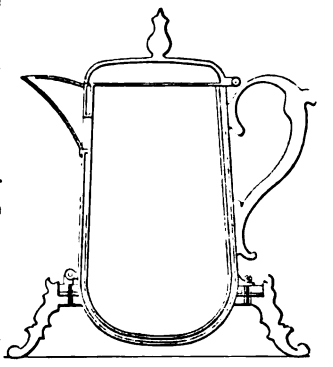
Lugo and McPherson. The air from a blower is forced through a chamber containing porous material saturated with water, and being there cooled is conducted to a condensing-pump, the upper part of which contains water, serving to keep the pump cool and pack the piston. The piston is driven by the epicycloidal combination of La Hire. From the pump the air passes to a cooler, and thence to a reservoir, from which it is conducted to a large congealing chamber or ice-house, which has non-conducting walls and a track for cars carrying pans of water.

Ice-mark'er. A species of plow for grooving pond ice in the line of the future lines of separation by the saw, or fracture by spades and axes. See *a*, Fig. 2658, ICE-TOOLS.

Ice-pick. (*Domestic.*) An awl-shaped tool to break ice into fragments.

Ice-pitch'er. A metallic pitcher with non-conducting interval between its double sides. In the example, it is supported in a stand in which it may be rotated or tilted forward.

Fig. 2647.



Ice-Pitcher.

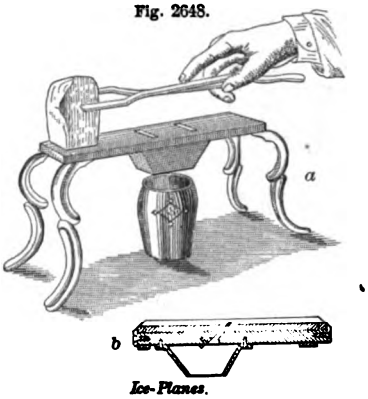
Ice-plane. 1. A tool for dressing the surfaces of ice-blocks before stowage in bulk.

2. An instrument for shaving off fragments of ice for cooling drinks.

a is placed on a stand, *b* is of similar construction but not mounted.

Ice-plow. A tool for cutting grooves in pond ice, to facilitate its fracture or cleavage into square blocks for landing, transportation, and stowage.

Fig. 2648.

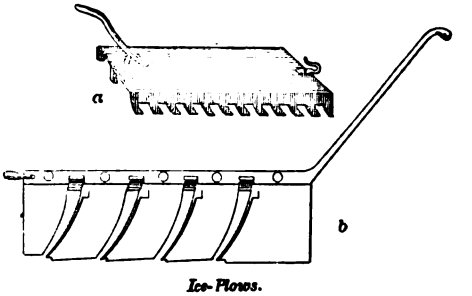


Ice-Planes.

The upper figure *a* is a frame which cuts three parallel grooves in moderately thick ice.

The lower figure *b* has five consecutive shares,

Fig. 2649.



Ice-Plows.

which make and follow in the same groove in cutting deep ice. See also *a b*, Fig. 2658.

Ice-pre-serv'er. A cover for an ice-pitcher to economize the ice by keeping the warm air from contact with the outside of the pitcher. It is made of straw, woolen, or cotton felt, and lined within and covered without with flannel. The top is made of wood, to give form to the cylinder, and has a

Digitized by Google

Fig. 2650.

Ice-Preserver.

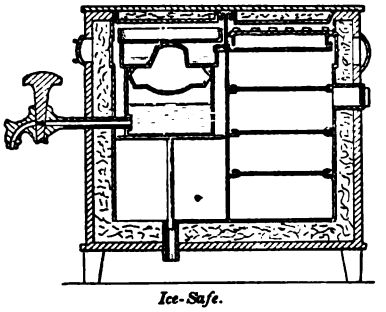
handle for convenience in raising it.

Ice-safe. A chest in which provisions are kept cool by the presence of ice.

The box and the cupboard forms are the more usual, and the safe sometimes is made quite ornamental for a dining-room.

In the example (Fig. 2651), the space between the inner metallic case and outer wooden one is filled with pulverized charcoal, and a wooden rack supports the ice. Air-passages connect the ice-chamber to the cooling chamber below. A tube carries the water from the ice-chamber to the filter.

Fig. 2651.

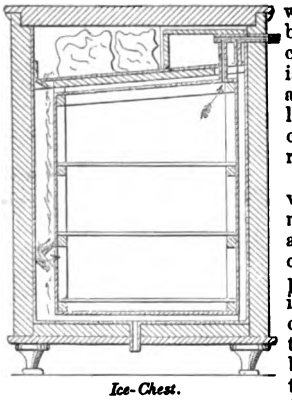


Ice-Safe.

The chambers are ventilated by pipes from the outside.

In the ice-safe Fig. 2652 the ice is on the slanting top of the food-chamber, and the water drips down the back, inducing a current of air which is cooled by contact and caused to circulate through the chamber in the direction of the arrows.

Fig. 2652.



Ice-Chest.

Fig. 2653 has revolving shelves. A removable tube, with a perforated cap at one end and a diaphragm at the other, is fitted in the ice-chamber, which, with the refrigerator chamber, has a removable top of two lids hinged together. Two dead spaces, one inside of the other, surround the sides of the cylinder and the refrigerating space, and a trough with discharge-pipes runs around the outside wall at the bottom.

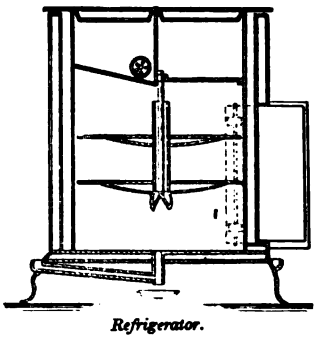
Ice-san'dal. A clog or shoe to be worn over the boot, and having spurs on the sole to prevent slipping on ice. (Fig. 2654.)

Ice-saw. A long saw with a weight at the lower end (beneath the ice), for cutting long kerfs in pond ice, to make a track for vessels, or to form long slices which are broken in blocks for storage.

Ice-saws in the Arctic regions are made of $\frac{5}{8}$ to $\frac{3}{4}$ inch steel blades, 10 to 24 feet long. See *h*, Fig. 2658, ICE-TOOLS.

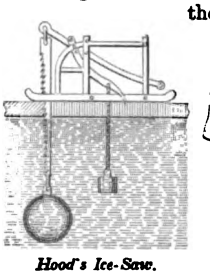
Hood's ice-saw (English) is mounted on a sled, which is advanced a given distance during each cut, by means of a lever-dog. The saw is suspended from the end of a brake-lever, the weight suspended at the lower end giving the effective stroke, while the men at the brakes raise it between cuts.

Fig. 2658.



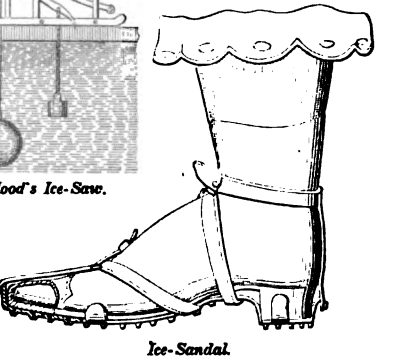
Refrigerator.

Fig. 2655.



Hood's Ice-Saw.

Fig. 2654.



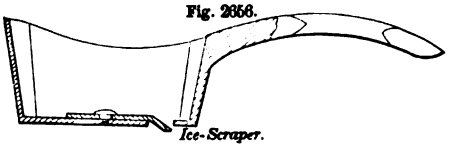
Ice-Sandal.

At each end of the saw is a link or clevis, by which it is attached to the brake-lever and the weight, respectively. The weight is of the shape of a double convex lens, so as to offer as little impediment as may be to its vertical motion in the water below the ice. The propeller is an iron bar having two claws at its lower end, by which it catches a foot-hold on the ice, and at top is a fork which embraces the lever and is suspended therefrom by a transverse pin. A weight is hung to the propeller to keep the toe-calks in contact with the ice. A transverse bar limits the upward throw of the brake-lever.

The saws are used in cutting ice for storage, but their principal use has been in northern latitudes, in cutting passages out of the ice floes and fields, in which vessels have become entangled and frozen up.

Ice-scrap'er. An implement to clean and remove snow from the surface of ice which is to be cut and stored for use.

Fig. 2656.

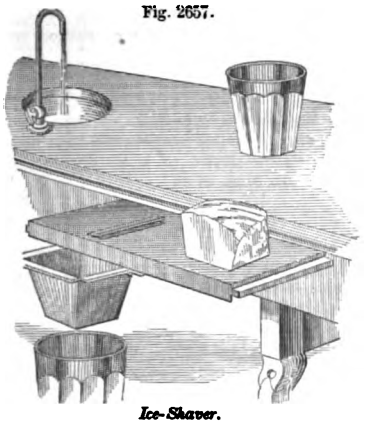


Ice-Scraper.

Ice-shav'er. A device for planing ice to cool a beverage in a tumbler.

Digitized by Google

Fig. 2657.



Ice-Shaver.

Ice-spade. A tool for cutting ice. See *m*, Fig. 2658, ICE-TOOLS.

Ice-tongs. Grasping implements for carrying blocks of ice; or, on a small scale, for handling pieces of ice at table. See *j k*, Fig. 2658.

Ice-tools. Fig. 2658 shows an assortment of

Fig. 2658.

cast-steel ice-tools made by Stafford, Holden & Co., of Barre, Vermont: —

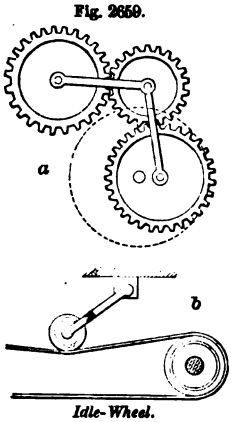
a is a marker.
b, cutter with guide.
c, a hand-cutter.
d, grapple.
e, striking-off bar.
f, chisel-bar.
g, hook and pick.
h, saw.
i, hatchet.
j, hoisting-tongs.
k, landing-tongs.
l, snow-planer.
m, ice-spade.

Ich'no-graph. (*Drawing.*) A ground-plan; an *orthograph* is a front elevation, a *scenograph* a general view.

I'dler. A cog-wheel (as at *a*) placed between two others to communicate the motion of one to the other. By its interposition they are caused to rotate in the same direction, which would be otherwise if they geared directly into each other.

Another description of idle-wheel (as at *b*) is caused to rest upon a belt to tighten it, to perfect its adhesion to the band-wheels over which it runs.

Fig. 2659.



Idle-Wheel.

I'dle-wheel. See IDLER.

Id'wall-stone. A Welsh oil-stone from Snowdon.

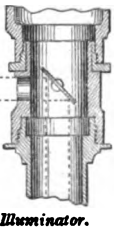
Il-lu'mi-na-ted Clock. This practice appears to have commenced in Glasgow, Scotland, where a clock with two faces supported at the extremity of a projecting bracket was lighted by jets placed above it, the light of which was reflected upon the dials from mirrors placed beneath a carved phœnix which surmounted the clock. The jet was lit by a *flash-pipe*, which consists of a supplementary pipe pierced with a row of small holes throughout its length. Gas issuing from each of these is lit, and forms a communication between the match of the lighter and the issuing gas of the burner.

The more usual plan of illuminating clocks is to make a transparent dial-face, having figures thereon which show dark on a light ground. The dial-chamber is illuminated in the ordinary manner. The church-clock of St. Giles, in the Fields, London, was lighted April 23, 1827.

For modes of lighting the gas without climbing to the tower or spire, see GAS-LIGHTING BY ELECTRICITY.

Il-lu'mi-na-tor. A device to throw light upon an object in an optical instrument; such as a lens which condenses light upon an object under observation, or a lamp which throws a pencil of rays upon the micrometer wires in a telescope.

Fig. 2660.



Illuminator.

Beck's *opaque illuminator* for high powers consists of a circular disk of thin glass placed at an angle of 45° in the axis of a microscope, receiving rays from a lateral aperture, and directing them downward upon the object. The *objective* is made its own condenser.

The *white-cloud* illuminator is to transmit a subdued white light, and is sometimes a surface of pounded glass or of plaster of paris.

The *oblique illuminator* is for directing oblique rays upon an object. This is attained by the concave mirror, Amici's prism, etc.

The *black-ground illuminator* places an opaque surface behind the object and illuminates the surface. See SPOT-LENS; PARABOLIC ILLUMINATOR.

To these may be added the various illuminators for opaque objects, and known as CONDENSERS, SIDE-REFLECTORS, PARABOLIC REFLECTORS, LIEBERKUHNS, etc. (which see).

Il-me'ni-um. Symbol, *Il.* One of the rare

Digitized by Google

metals but little known beyond the laboratory of the chemist.

Im-bow'ment. (*Architecture.*) A vault or arch.

Im'bri-cat-ed. (*Architecture.*) Overlapping; as tiles or shingles on a roof.

Im-i-ta'tion-met'als. See MOCK-GOLD; MOCK-SILVER, etc.

Im-mer'sion-lens. (*Optics.*) An achromatic objective for the microscope, which is used with a drop of water between the front lens and the glass cover of the object examined, to prevent the extreme refraction of the luminous pencils if air is present, as in ordinary microscopical examinations, and which thus secures better definition and longer working distance for the same power.

Im-pa'ges. The horizontal parts of the framework of doors, commonly termed rails.

Im-pe'ri-al. 1. A baggage-case on the top of a traveling-carriage.

2. A roof with a pointed or tent shape.

3. A size of paper, variously quoted as to sizes; paper-makers differ.

Printing-paper, 22 × 32.

Flat writing-paper, 22 × 30.

Blank-book paper, 22 × 30 to 23 × 31.

Im-plu'vi-um. The cistern in the central part of the court or atrium of a Roman house, to receive the rain-water.

Im-pos'ing. The arrangement of pages in a form.

When wedging up the *form* in the *chase* the form lies upon the *imposing-stone*, and the various pages are arranged so as to match their fellows on the other side of the sheet, so that when folded the pages shall come in consecutive order.

The *number of pages on one side of the sheet* determines its name, as follows: —

Folio, 2 pages.	Duodecimo (12mo), 12 pages.
Quarto, 4 pages.	
Octavo (8vo), 8 pages.	16mo, 18mo, 24mo, etc.

When perfected, that is, printed on the other side, the sheet has double the number, so that there are 8 pages to a quarto signature, 16 to an octavo, etc.

They are imposed as follows, the illustration showing how the pages appear in the form.

O. F., outer form; I. F., inner form.

18, 24, 32, and 48mo may be imposed in a similar manner, or may be so imposed as to be cut before folding. See Ringwalt's "Dictionary of Printing."

Im-pos'ing-stone. (*Printing.*) A slab on which the type is made up into forms. The *chase* lies on the *stone*, and the *matter* is arranged inside, being keyed up by the *quoins*.

Im'-post. The upper member of a pillar, column, or entablature, upon which an arch or superstructure rests. A *plat-band*.

The upper stone of a pier or abutment, upon which the *springing* or bottom stone of an arch is imposed.

Imp-pole. (*Building.*) A pole serving to support the scaffolding. A scaffolding *imp*.

Im-pres'sion. (*Printing.*) The pressure applied to a sheet in the press. Also the appearance of the sheet, front or back, when it is taken from the press.

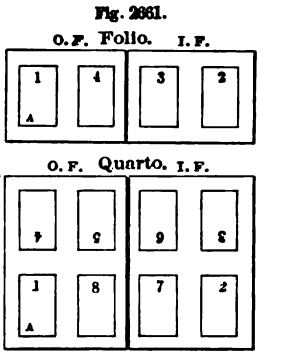
Making ready is to prepare press and form for printing. When some lines or letters in a form have been worn longer than the other type, a piece of paper is pasted on the bottom of these lines to raise them to the proper height. This is called an *underlay*.

When type or stereotype plates give a *faint impression* in spots, a piece of tissue paper of the size and shape of the spot is pasted upon the *tympan*. This is called an *overlay*. When the whole sheet has a gray or light appearance, the impression is regulated by turning up the impression screws of the press. Too much impression on a sheet raises the paper so that the letters show in relief on the back of the sheet.

A sheet is *cockled* or *wrinkled* when it folds over so that any portion shows a *streak* of white paper after printing.

Some presses give a

Fig. 2661.



Imposing.

dwelling impression by holding the type and paper in contact for some instants. Lithographic presses give a *drawing* impression.

A sheet is *slurred* when it is allowed to slip upon the face of the type after inking. It is *smeared* after printing by handling or folding while *green*, or before the ink is *set*. Dry pressing printed sheets flattens down the impression and fixes the ink, though if pressed while too wet the ink may *offset*. *Monks* and *friars* are black or white blotches which may appear on a sheet from imperfect distribution of ink on the *rollers* or *form*.

Digitized by Google

Im-pres'sion-cup. (*Dentistry.*) A cup to hold material for taking an impression of the mouth for the purpose of making an artificial denture.

In-and-out-bolt. A *through* bolt. One passing through a ship's planking, the frame, and the knees of the beams.

In-boards. (*Bookbinding.*) The sides covered with paper.

Cut-in-boards: leaves cut after the cover is on.

Out-of-boards signifies that the edges are trimmed before covering.

In-cen'di-a-ry Com'pounds. Greek-fire, said to be the invention of Callinicus of Heliopolis, in Syria, in the seventh century. It was first used upon the Saracens' ships. It was blown out of long tubes of copper, shot out of cross-bows, and projected in other ways. It burned on water, and diffused itself on all sides.

The composition of Greek-fire was kept as a state secret in Constantinople. It is believed that it contained sulphur and nitrate of potash mixed with naphtha. See GREEK-FIRE.

The Arabs had an incendiary composition formed of sulphur, saltpeter, and sulphide of antimony, mixed into a paste with juice of black sycamore, liquid asphaltum, and quicklime.

The French engineer Chevallier, about 1797, invented a compound which would burn under water.

Shells, charged with this or a similar substance, are said to have been found on some of the ships of the French fleet which carried Napoleon and his army to Egypt, and were afterwards taken or destroyed by Nelson at the battle of the Nile.

Rock-fire is one of the best known modern incendiary compositions; it burns slowly, is difficult to extinguish, and is used for setting fire to ships, buildings, etc. For putting in shells it is cast in cylindrical paper cases, having a priming in their axes.

Rock-fire is composed of rosin, 3 parts; sulphur, 4; niter, 10; regulus of antimony, 1; mutton-tallow, 1; turpentine, 1. These are combined by pulverizing the sulphur, niter, and antimony separately, mixing them by hand, and passing them through a sieve; the tallow is melted over a fire, the rosin is then added, next the turpentine, and afterward the other materials; the whole being thoroughly incorporated by stirring with spatulas, and great care being taken to prevent its taking fire. When the composition becomes of a brown color the fire is permitted to go down, and when sufficiently fluid is poured into the paper cases.

Niepce experimented upon the effects of potassium and benzole, and ascertained that ½ gramme of potassium in 300 grammes of benzole would spontaneously ignite on the surface of the water, burning and spreading over a considerable surface. Petroleum may be substituted for benzole. A solution of phosphorus or chloride of sulphur, in sulphuret of carbon, also spontaneously ignites on exposure to the air.

In-cen'di-a-ry-shell. A hollow projectile charged with incendiary composition, and designed for setting fire to buildings, ships, and other objects. Hollow balls, filled with fire, appear to have been among the earliest projectiles used in warfare after the introduction of the Greek-fire, though these were not fired from cannon; but descriptions are given of balls of fire used by the Saracens in Spain, which seem to correspond closely with modern incendiary-shells. The use of incendiary compounds appears to have gradually become obsolete, as we hear little or nothing of their employment until toward the close of the eighteenth century, hot shot being used as a substitute.

About 1797, Chevallier, in France, invented an incendiary compound, which seems to have been tried to a limited extent by the French government, for filling shells. Since then, many inventors have exercised their ingenuity upon this subject, the principal object being to obtain an inextinguishable composition for charging shells, to be ignited either by time-fuse or by percussion.

The only shells of the incendiary kind generally recognized in modern warfare are CARCASSES (which see).

In-cer'tum. A form of masonry made of a facing of square stones of irregular sizes and a filling of rubble. *Rubble-work.* See MASONRY.

Inch. The $\frac{1}{36}$ of a yard; the $\frac{1}{12}$ of a foot. The yard is the standard in England and in North America. See UNIT.

In'cli-na-tion. (*Compass.*) One of the three elements of magnetic force which are registered at the observatories. The other elements are the *declination* and *absolute intensity.*

The *inclination* or *dip* is the vertical angle of a freely suspended needle which it makes with the horizon. It has a general dependence upon the latitude, but varies from local causes. See DIPPING-NEEDLE.

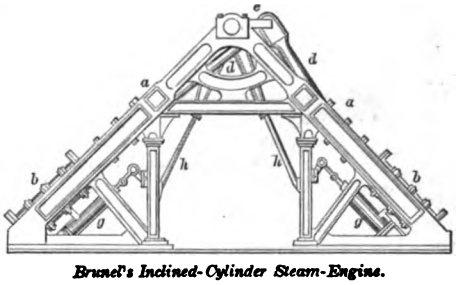
In'clin-a-to'ri-um. The dipping-needle invented by Norman, of London. See DIPPING-NEEDLE, also MAGNETOMETER.

In-clined'-cyl'in-der Steam-en'gine. A form of *direct-action steam-engine*, in which two cylinders are placed in a frame so as to work at an angle to each other, the connecting rods giving motion to the same crank.

It was invented by Brunel, and patented by him in 1822.

a a is a strong triangular frame of cast-iron, within which are fixed the two cylinders *b b*. Mr. Brunel preferred that the angle formed by the axes of the

Fig. 2662.



Brunel's Inclined-Cylinder Steam-Engine.

cylinders should be 102°. *d d* are the connecting rods attached to the crank *e*, which gives motion to the paddle-shaft.

The piston-rods are supported upon rollers, which traverse on guide-plates to preserve their parallel motion during the stroke. In the small cylinders *g g* are piston-valves by which the steam from the boiler is admitted to the alternate ends of the cylinder and allowed to escape from the other end. The action of the piston-valve is regulated by the eccentrics on the paddle-shaft. These eccentrics give motion to the rods *h h*, which, by intermediate levers, operate upon the pistons in the small cylinder.

This is one of the numerous devices intended to obviate the use of the beam in marine engines.

Digitized by Google

In-clined' Plane. An artificial slope forming an ascent for vehicles; the climbing passes for pedestrians perhaps hardly deserve the name.

Stevinus, in his work on the principles of equilibrium, 1586, established the fundamental property of the inclined plane, and solved the value of forces acting obliquely. Galileo's treatise on Mechanics appeared a few years later.

In various parts of the old countries of Europe and Asia are the remains of vast engineering works on the main routes of travel and conquest.

It is supposed that the grade on the great canal of Sesostris (1500 B. C.), which united the Red Sea and the Nile, was overcome by a sluice; probably an inclined plane down which the water ran. The difference in level is but slight, and perhaps on account of the fear of the contamination of the fresh water of the river by the salt water of the sea, it may really have been an inclined plane like that which crossed the Isthmus of Corinth some centuries afterward. The sluice preceded the lock in Europe (see CANAL), and was probably used also in the grand canal of China, built in the ninth century A. D. The canal lock was invented in Italy in the fourteenth century.

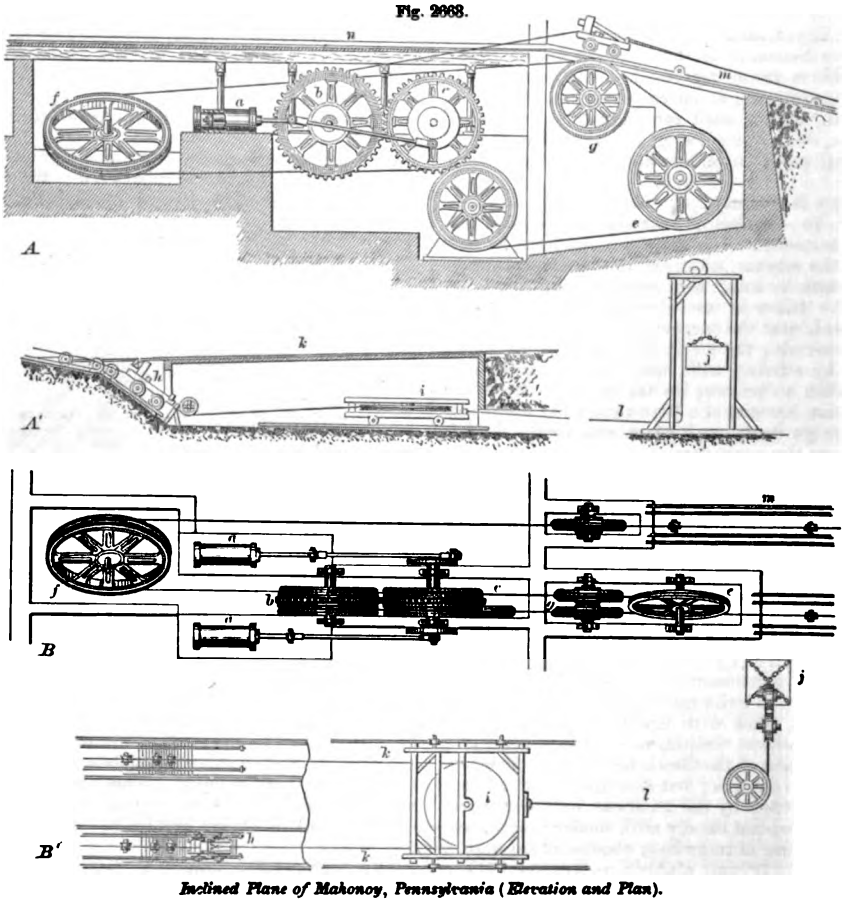
On the Mount Cenis Railroad, which crossed between Savoy and Italy previous to the completion of the tunnel, the elevation is overcome by a series of inclined planes, with mechanical devices to cause a positive grip upon the rails, instead of depending upon frictional contact for the tractile effect of the motor. The railway tunnel has superseded the mountain road.

On the old line of the Pennsylvania Railroad by Hollidaysburg, the reader may have noticed and admired the inclined planes by which the summit and several other gradients were ascended; stationary engines at the summit of each grade hoisting or lowering the cars by means of ropes. The London and Blackwall Railway was operated in a similar manner, though the road was about level.

The Portage Railway formerly occupied a nearly central position on the main line of the Pennsylvania Canal, between Columbia and Pittsburg, and extended from Hollidaysburg, on the eastern base, to Johnstown on the western base of the Alleghany Mountains, a distance of thirty-six miles; the total rise and fall on the whole length of the line being 2,571.19 feet. Of this hight, 2,007.02 feet were overcome by means of ten inclined planes, and 564.17 feet by the slight inclinations given to the parts of the railway which extend between these planes. The distance from Hollidaysburg to the summit-level is about ten miles, and the hight is 1,398.31 feet. The distance from Johnstown to the same point is about twenty-six miles, and the hight 1,172.88 feet. The hight of the summit-level of the railway above the mean level of the Atlantic is 2,326 feet.

The machinery by which the inclined planes were

Fig. 2668.



Inclined Plane of Mahonoy, Pennsylvania (Elevation and Plan).

Digitized by Google

worked consists of an endless rope passing round horizontal grooved wheels placed at the head and foot of the planes, which are furnished with a powerful brake for retarding the descent of the trains. The ropes were originally made 7½ inches in circumference, but were afterwards increased to 8 inches to give them a better bite in the grooves of the wheels over which they passed. Two engines of 25-horse power each were placed at the head of the inclined planes, and were used alternately, week about, the duplication being for the purpose of security in case any accident happened to one of them. The traction rope passed around a horizontal grooved wheel driven by the engine.

The planes were laid with a double track of rails, an ascending and a descending car being attached to the respective ends of the rope at the same time. A safety-brake was attached to each car, which was attached by two ropes of smaller size to the endless rope by a hitch or knot.

Locomotives were used on the intervening levels and slight grades.

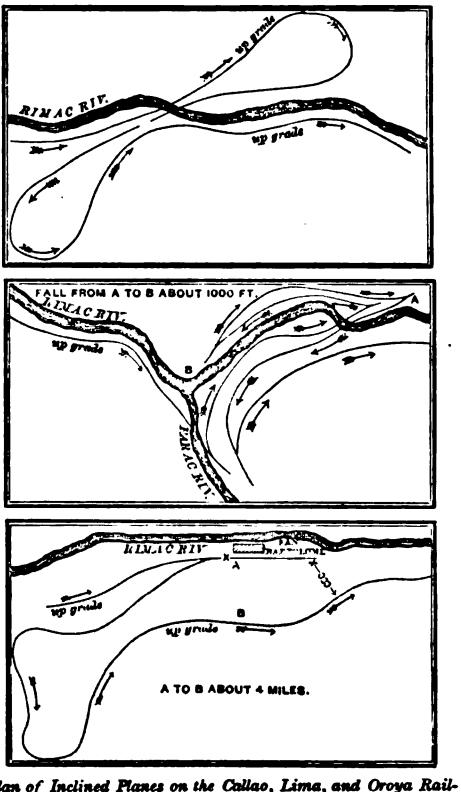
Fig. 2663 shows a side elevation and plan of the inclined plane of Mahonoy, Pennsylvania, up which the cars loaded with coal and other products from the mines of the valley of the Mahonoy are elevated by stationary engines and wire ropes. The length of the incline is about 2,400 feet, and the total elevation about 360 feet. It has two tracks of the usual gage, upon which the wagons ascend and descend alternately. Between each of the tracks are two narrower tracks, with rails about 40 inches apart, and which are traversed by trucks *h*, to which the hoisting rope is attached, and whose duty is to push the wagons traversing the wider track up hill, and also let them down gradually. The wire rope which moves the trucks passes over large pulley-wheels, with grooved faces, one *f* at the top, and the other *i* at the bottom of the plane. The pulley *f* at the top is on a fixed axis, but that at the bottom *i* is on a truck traversing a short track, and held at a certain tension by a rope *l* extending over a pulley on a frame, and with a suspended weight *j* of 3,960 pounds. By this means a regular tension is kept upon the draft-rope, notwithstanding changes of temperature of the wire rope. The same ties support both tracks and the frames of the pulley midway of the tracks which support the wire rope. These pulleys are 50 feet apart, and are from 9 to 14 inches in diameter. The cable is a little over 2 inches in diameter, the lower cable about 1½ inches. The core of the cable is formed of 7 strands, each of which is formed of 7 wires; the exterior surface is 6 strands of 19 wires each. The cable has a spring attachment to the truck. The usual lift is 12 wagons at once. At the foot of the incline the truck runs into a pit below the track, and ascends in the rear of the last car of a train of 10 made up for ascent. In the descent of the empty cars, when the truck runs into the pit, the wagons continue to run by their acquired impetus upon the track *k*, the truck descending on the diving narrow track, as shown at the portion of the figure marked *A'*.

The hoisting apparatus is placed in an underground chamber at the top of the incline, beneath one of the two tracks. It is driven by two horizontal steam-engines *a a*, which turn the large drum *c*, and this is geared to the drums *b*. The drawing cable coming from one of the roads (say the lower one, shown in figures *B B'*), is bent by pulley *g*, and passes over one side of drum *b*, underneath it, and thence between it and drum *c*, then over the latter, encircling one half its periphery, and nearly describing a figure ∞; it then dives, goes under the drum below *c*, under *e*, recurves upwardly over *e*, then again over *g*, following another groove to its former course, the pulley *e* being set obliquely so as to give the rope the lateral deviation. To resume: the rope, passing back over *g*, goes over pulleys *b* and *c*, repeating its figure ∞ course, coming out under *c* and going around *f*, and thence to the car on the upper of the two tracks, as shown in the plan *B*. The pulley *F* is set obliquely so as to change the rope over to the other track. *n* is the level railway at the head of the slope *m*.

The parts have been disjointed for convenience of disposition on the page; the part *A'* belongs at the right hand of *A*, a long intervening stretch of 2,400 feet of wire being understood. The same may be said of the proper position of *B'* at the right of the portion *B*, which is a plan of the machinery at the head of the incline. The steam cylinders are 32 inches in diameter, and 7 feet stroke. The drums make 32 revolutions in a minute, the velocity of the rope being 1,400 feet per minute.

Some magnificent engineering works are to be found among the mountain regions of the world, where the grades are ascended by inclined planes. Among these may be cited some on the Callao, Lima,

Fig. 2664.



Plan of Inclined Planes on the Callao, Lima, and Oroya Railway, Peru.

and Oroya Railway in Peru. The annexed engraving shows portions at Surco, the Parac, and San Bartolome, respectively. They are not "air lines" by any means. The grades are from 2½ to 4 per cent (211 feet to the mile); curves are limited to 400 feet radius.

Mr. Meiggs is doing a great work. The western slope of the Andes at this point has no timber, nor

Digitized by Google

for fifty miles on the east side. Oroya is thirty miles east of the summit tunnel, which is 15,200 feet above the level of the sea. At this hight you cannot cook beans in an open vessel, as the boiling-point is not hot enough. The railroad buildings and bridges are of iron, and come from England, as do the rails; the ties are from Oregon, the locomotives and cars from the United States.

The plate opposite is a view of the Furka pass and the Rhone glacier, Canton Valais, Switzerland. The winding road is shown in the view, climbing up a spur of the mountain, which is immediately west of Mt. St. Gothard. See also views in "Lippincott's Magazine," Vol. VIII. p. 324; and London "Engineer," Vol. XXXII., 1871, p. 233.

The longest inclined plane on an artificial road is said to be that from Lima to Callao, which is about 6 miles, and has a descent of 511 feet, or about 1 in 60.

The ascent from the Konkan, or flat country of Bombay, by the Western Ghauts to the table-land of the Deccan, is known as the Bhore Ghaut incline, in which the railway rises from the plain 2,000 feet in a series of steps 16 miles in length.

The Righi Railway in Switzerland rises by a locomotive of peculiar form 1,170 feet in traversing 4,700. The boiler, furnace, and carriage are inclined so as to present a level floor on the slope.

The inclined plane or railway of Mt. Washington is familiar to many tourists.

In this connection the following data may be useful: —

The pressure on a level pike against the collar is, say, $\frac{1}{3}$ of the load. An ascent of 1 in 35 would double the draft, and may be a suitable maximum ascent. The French maximum is 1 in 20. Telford's maximum was 1 in 30. Simplon, Italian side, average 1 in 22; Swiss, 1 in 17.

Inclined planes were used for raising the galleys and triremes of the Greeks from the waters of the Corinthian or the Cenchreæn Sea, for transportation across the Isthmus of Corinth. This was the *Diolcos* or drawing-place, 40 stadia or 5 miles in length, the narrowest passage between the two gulfs. A canal was attempted at this point by Julius Cæsar, Caligula, Nero; the ridge of native rock defeated all the attempts; it is very hard, and can hardly be worked without blasting. The incline was again used in the wars of the Genoese and Turks.

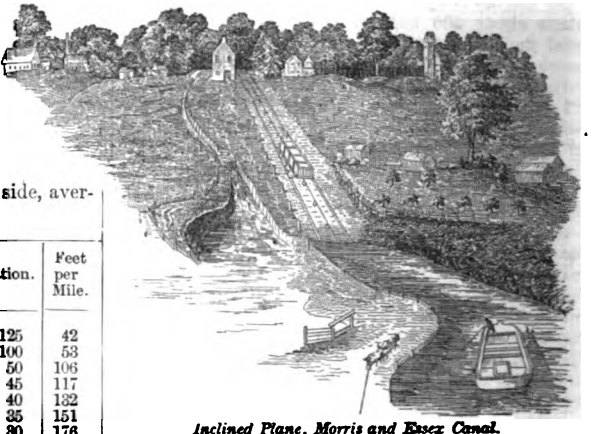
Inclined planes and *lifts* for raising and lowering canal-boats from one level to another, as a substitute for locks, are mentioned by Smeaton in 1774. Both systems are used on the English canals, in the neighborhood of Taunton; 80 feet of rise are overcome in this way.

The *inclined plane* has a steam-engine on the summit, which, by means of a drum and chain, hauls up the cradle containing the boat.

The *lifts* are worked by one attendant, who can raise or lower a boat from one level to another. There are two lock-chambers, over which is a lofty frame, having large wheels and chains, by which are suspended the cradles, into which the boats are floated when they are to be raised or lowered. See LIFT.

On the Morris and Essex Canal, which crosses the State of New Jersey, connecting the Hudson and Delaware Rivers, there are, or were, 13 inclined planes, up which the canal-boats are hauled, the grades being thus ascended and descended without locking. The summit level at Stanhope is 900 feet above tide-water, and the changes of grade are sudden and frequent. A track of heavy rails is laid on the inclined plane, which has a grade of about 15°, and on this the cradle containing the boat ascends at the rate of five or six miles an hour. At the summit is the motor, consisting of a water-wheel, driven by the water on the upper level. The wheel is connected to a shaft carrying a drum, on which is wound a wire rope about two inches in diameter, and connected at either end to the cradle which contains the boat, and which forms a car for its conveyance. This car is a heavy frame running on flanged wheels, and descends a sufficient distance into the water to

Fig. 2665.



Inclined Plane, Morris and Essex Canal.

enable a boat to float into it, where, being secured, the car and boat ascend or descend the inclined plane together. From the forward end of the car the wire rope passes over anti-friction rollers between the rails of the track to and around a large submerged wheel some 100 feet distant from the summit, thence over the drum and other friction-rollers by the side of the track to another submerged wheel at the foot of the plane, around which it passes, and is attached to the rear end of the car. The boat is made in sections, to enable it to accommodate itself to the inequalities of the track when passing over the summit.

Arriving at a plane, the boat is drawn into the car in the order of its arrival, the team is unhitched, the tow-rope coiled on deck, the boat secured to the car by hawsers, and its two sections disconnected by a lever which pulls out the bolt uniting the hinge. The blade of the rudder is then raised out of harm's way, and the signal is given for the engine to start. After passing the summit the brakes are put on, and the car descends into the water where the boat floats out of it, and the tow-rope is again attached. In one place the canal has a fall of 200 feet, 80 of which are overcome by a single plane of 800 feet length, and the remainder by means of locks.

A mode by which canal-boats are enabled to ascend inclined planes while preserving their usual horizontal position was invented in England, but it is not known to the writer whether it was ever successfully put in practice. The carriage which received the boat had a forward pair of wheels which ran upon one double track, while the rear end (to the ascending boat) was supported by other wheels, which ran on another track set at such a distance outside of and higher than the former as to give the required level position to the carriage. The inclined boat-carriage is also shown in Day's United States patents for inclined planes and cradles for canal-boats.

In-cli-nom'e-ter. 1. An instrument to detect the inclination or dip, the vertical element of the magnetic force. Many delicate instruments have been constructed for this purpose, but the best known is the DIPPING-NEEDLE (which see).

2. An instrument to measure the slope of an embankment, slope, or incline. It may have an alidade with a level; an arc, and a base-piece which lies on the slope. A *batter-level.*

In-crease'-twist. (*Rifling.*) A rifle-groove which has an increased angle of twist as it approaches the muzzle, allowing the projectile to be easily started and giving it an increased velocity of rotation as it proceeds.

Rifling was known in the seventeenth century; its inventor and date being unknown. Mere grooved barrels, without spirality, were used two centuries earlier.

The increase twist is credited to Tamisier, and dates but a few years back.

In-crus-ta'tion. 1. (*Masonry.*) A facing or covering to a wall of a different material from that of which it is mainly built, such as marble or stone.

2. A thin sheet of wood applied upon a wooden surface. See VENEERING.

3. (*Steam-engine.*) The deposit from the water adhering to the inside of a boiler.

As nothing but pure water enters into the composition of steam, it has long been a problem in steam-engineering to get rid of impurities in water which it is found necessary to use in steam-boilers. Among these impurities may be mentioned the salt in sea-water, lime in the water of limestone regions, and minerals in many forms, which are often found in water supposed to be pure until thus tested.

The accumulation of salt in a marine boiler would soon fill it, if there were no way for its removal. In practice it is generally "blown off," when the *salinometer* indicates a certain point of saturation.

Lime in some forms incrusts a boiler very rapidly, having been known to form a *scale* several inches in thickness in a few days. This scale is a poor conductor of heat, and a large proportion of the products of combustion are lost by its interposition. It also weakens the boiler, and has been the cause of many explosions.

Condensers are used to supply pure water to boilers. See CONDENSER.

Feed-water heaters have a purpose, besides utilizing waste heat, to compel the deposition of impurities before the feed-water reaches the boiler.

Mechanical agitators, beaters, scrapers, etc., are often employed to remove crust from a boiler.

Chemical treatment of feed-water, or of water in the boiler, is a matter which has received much attention from engineers and scientists. Sawdust acts both chemically and mechanically to prevent incrustation, the tannic acid it contains uniting with the lime to form tannate of lime, which deposits itself as a slimy body. Clay has sometimes given good results, but sand is almost always present in some quantity, though small, and, if it passes over in priming, is very detrimental to the valve-faces, the cylinder, and the piston. Starch and sugary substances have the effect to clarify some waters, the viscid character of the glucose preventing agglomeration of the foreign matters, and forming scum instead of crust. Fatty bodies, tar, and graphite tend to prevent adhesion. The nature of the water to be treated determines the substance which shall be used.

Scott's English patent, 1828, describes a mode of catching the deposit which forms the incrustation by placing pans or trays in the boiler; these intercept the falling deposit.

Taylor's English patent, 1830, has a sediment-trough the length of the boiler, and forming a narrow chamber below the same, out of contact with the fire. The contents of this chamber are occasionally blown out, carrying the sediment.

To avoid the expenditure of space in stating at length the various materials which have been placed in steam-boilers to retain the mineral particles in suspension, or to prevent their adherence to the boiler, it may be stated that they consist of —

In'cu-ba-tor. A device for hatching eggs by artificial means.

The hatching of poultry by artificial heat is not mentioned by Herodotus, but is described by Diodorus Siculus as an ancient practice. The ancients

Digitized by Google

obtained the heat by the fermentation of manure; the modern Egyptians by the regulated heat of ovens.

The ordinary domestic fowl is a native of India, and is neither mentioned in the Old Testament nor depicted on the paintings of Egypt. It was known in Palestine at the Christian era, and is supposed to have been introduced by the Romans into the countries they subjugated; perhaps earlier by the Persians, but this does not clearly appear. They were common in Greece.

The references to eggs in the Old Testament refer to those of wild birds, such as ostriches and partridges. That in Luke no doubt was the ordinary hen's egg. The word, in the singular or plural, occurs but twice in the Old Testament, five times in the New.

The business of egg-hatching is conducted by the Copts, who carry it on in Upper and Lower Egypt and pay a license to the government. A building containing from 12 to 24 ovens is called a *maamal*, and its charge is 150,000 eggs. An official report for 1831 gives for Lower Egypt 105 of these establishments, using 19,000,000 eggs, of which 13,000,000 produce chickens. This saves the valuable time of 1,500,000 hens for three weeks of inactivity and several succeeding weeks of care and scratching, enabling them to devote their undivided attention to the other duties of maternity, egg-laying and cackling.

The proprietors of an oven collect the eggs from the peasants in the vicinity. The eggs are placed on mats strewed with bran, and are changed to positions nearer to or farther from the heat of the fire-chamber till the expiration of six days, when they are tested by a strong sunlight for signs of the formation of the chicken; four more days in the warmest position, five days in a closed chamber, and they are then spread separately over the surface of the mats, being frequently turned and changed from one part of the mats to another during 6 or 7 days, outside air being carefully excluded. They are frequently tested for signs of life, the test being greater coldness than the eyelid of the attendant. The chickens appear within 21 days, but some with thin shells hatch earlier. The usual number that succeed is two thirds, of which half belong to the peasants and half to the proprietors of the oven.

The size of the building depends on the means of the proprietors; but the general plan is usually the same, being a series of eight or ten ovens and upper rooms, on either side of a passage about 100 feet by 15, and 12 in hight. The thermometer in any part is not less than 24° Reaumer (86° Fah.); but the average heat in the ovens does not reach the temperature of fowls, which is 32° Reaumer. Excessive heat or cold are equally prejudicial to this process, and the only season of the year at which they succeed is from the 15th of Imsheer (23d of February) to the 15th of Baramoodeh (24th of April), beyond which time they cannot reckon upon a sufficient percentage to make it a paying business.

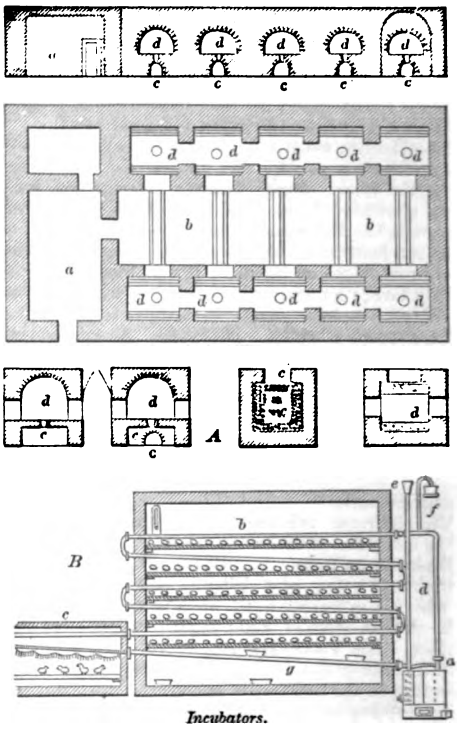
The illustration *A* (Fig. 2666) shows the modern Egyptian oven for hatching eggs.

a is the entrance room, and *b* the passage between the rows of ovens on each side. The chamber *c* for the eggs is below the one *d* in which the fires are made in troughs alongside the walls, the heated air passing to the chamber below by a hole in the floor dividing the two apartments. The illustration gives several horizontal and vertical sections, the entrances to the egg-chambers showing in the upper view at *c'*. The upper chambers are connected.

The ancient Egyptian incubators are referred to by Aristotle, Diodorus Siculus, and Flavius Vopiscus.

Bonnemain's incubator *B* (A. D. 1777) is heated by hot water. *a* is the boiler; *b*, a building for holding the eggs on shelves; *c*, a coop for holding the chickens; *d*, tube for circulating the hot water; *e*, a supply funnel; *f*, a safety tube. The hot water

Fig. 2666.



Incubators.

rises from the boiler into tube *d*, thence follows the sinuous course of the tube above and below each shelf, and into the chicken-coop, eventually discharging into the boiler again by the pipe *g*.

There is some difference in temperature in the interior of the box as the convoluted pipe parts with its heat sufficiently to establish a circulation in the pipe.

The force of the circulation is in the ratio of the difference between the temperature of the water, passing out of the calorifère and re-entering it; any unusual degree of coldness in the lower part of the box will thus react, and increase the speed of the circulation, the normal tendency of the scheme being towards equalization.

The point to be regulated is the heat of the furnace, and this is accomplished by a thermostat, founded upon the unequal dilatation by heat of different metals. A compound metallic bar exposed to the heat of the chamber warps when the heat exceeds the medium, and draws upon a wire connected to the door of the ash-pit, and thus regulates the draft.

Pans of water secured the proper humidity of the air.

Periods of incubation; temperature, 140° Fah.

Swan	42 days.	Peafowl	28 days.
Goose	35 "	Duck	28 "
Hen	21 "	Pigeon	14 "
Turkey	28 "	Canary	14 "

In-dent'. 1. (*Carpentry.*) A notch, as in scarfing timbers together.

Digitized by Google

2. (*Printing.*) The blank space or *set-in* at the commencement of a paragraph.

In-den-ta'tion. (*Architecture.*) A zigzag molding. The shark's tooth molding. *Denticulation.*

In-dent'ed Chis'el. A boring-chisel whose face is in steps.

In-dent'ed Line. (*Fortification.*) One consisting of alternate salient and receding angles, each face forming a flank to its neighbor.

In-dent'ed Par'a-pet. (*Fortification.*) One whose interior slope has vertical recesses in which men may stand and fire along the front of the work.

In'de-pen'dent Piece. (*Shipbuilding.*) The main piece of the *head* or beak-shaped projection from the stem of a vessel. See STEM.

In'de-pen'dent Sec'onds-watch. A watch in which the action of the center seconds-hand is independent of the regular going works of the watch. It has two separate trains of wheels and separate springs, so that the regular time may be maintained when the center seconds-hand is stopped by pressing the stop-pin on the outside of the case.

The center seconds is set in conformity with the other works by a *square* at the back of the case.

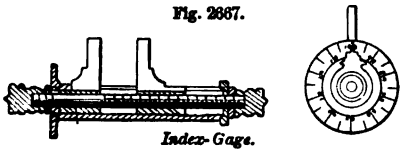
For great nicety in timing, quarter and fifth second watches are now made, and are capable of being stopped at the said fractional parts of a second.

In'dex. 1. A pointer, as the hand of a watch or clock, a finger or arm of a balance or measuring apparatus which moves along a graduated scale, or in relation to a line or central mark.

2. A brass rule accompanying the plane-table, furnished with perpendicular sight-vanes at each extremity. An *alidade.*

In'dex-gage. An instrument having jaws whose distance apart is indicated by a pointer and dial, or other means. In the example, the body to be measured is placed between the jaws, which are brought in contact with the opposite sides. The thirty-seconds of an inch are indicated by the jaw on the scale on the cylinder, and the hundredths of a thirty-second are indicated by the hand on the dial.

Fig. 2867.



Index-Gage.

In'dex-glass. A mirror at the center of motion of the index-arm of a quadrant or sextant, which moves with the index, and from which a ray of light from one of two given objects (one of which is, say, the sun) is reflected to another mirror, called the *horizon-glass*, fixed to one of the arms, and thence to a sight-hole in the other arm. See QUADRANT; SEXTANT.

In'dia-ink. A composition of lampblack and size. Said to have been formerly made from the pigment of the cuttle-fish. The ink of the Chinese scribe, used with a brush.

In'di-an Steel. A fine kind of steel, made in Southern Asia direct from the ore, and known as *wootz.* The *natural* steel of India.

In'dia-pa'per. The name given to a paper made with one exceedingly fine surface, and used for taking the finest impressions of steel, steel-plate, and wood engravings. It is made by the Chinese from the inner bark of the bamboo. It is imported in sheets 25 × 26 inches. The Chinese also make paper of the barks of the elm and mulberry, of the cotton-tree, hemp, wheat-straw, rice, and rice-straw. See WOOD-PAPER.

In'dia-rub'ber. India-rubber in the crude state is prepared for manufacture by grinding the sheets in water, for the purpose of cleansing it. After this it is dried and subjected to the tearing action of toothed rollers, one of which revolves faster than the other. At this stage the vulcanizing material, consisting of ½ ounce of sulphur or more to the pound of rubber, according to the required hardness, is added and thoroughly incorporated. Various other ingredients, as sulphate of zinc, whiting, plaster of paris, lampblack, pitch, etc., in addition to the sulphur, are also employed for the purpose of hardening. The selection of these depends on the peculiar ideas of the manufacturer and the destined application of the material.

In making boots and shoes the rubber is passed in contact with cotton cloth, between heated rolls which rotate at different speeds, and is forced between the interstices of the cloth, to which it becomes firmly united. In some cases the rubber is drawn, either with or without the cloth, through rolls of equal speed, to a thickness suitable for the soles or uppers of shoes. The sheets thus formed are cut up, by suitable dies, into the proper forms for the soles and uppers, which are afterward cemented on a last by a solution of rubber dissolved in benzine. At this stage a coating of linseed-oil varnish is applied with a brush, and the shoe subjected to a heat of about 280° Fah., when the operation is complete.

In making hose or tubing, the rubber or rubber cloth is wrapped around a tube until the desired thickness is attained, and placed in a steam-heater at a temperature of about 280° Fah., which partially fuses the compound, causing the layers to unite. It is then removed from the heater and the tube withdrawn.

Belting is formed by laying together a sufficient number of layers of the vulcanized gum or gum-cloth and subjecting them to the action of a flat press at a heat of 280° Fah. Additional hardness is attained by the use of a larger proportion of sulphur and the application of greater heat.

The operation of uniting several layers of the material is, however, performed with much more expedition by the use of a steam cylinder-press.

Previous to 1821, it is said that india-rubber had only been brought to this country as an article of curiosity, molded into various fancy forms, as alligators and other reptiles. In that year a pair of what appeared to be solid models of shoes were brought home by a sea-captain, who presented them to an ingenious boy. Curiosity led him to cut into them at the instep, when he found a clay mold inside, this he removed, and finally, by dint of heating and stretching, adapted them for wear. This becoming known, led to the importation of the native shoes made upon clay lasts. See CAOUTCHOUC.

No process has yet been devised for restoring old rubber to the condition in which it was previous to vulcanization. It is, however, extensively used for mixing with new raw material in the manufacture of all kinds of rubber goods. By steaming and rolling it is reduced to a semi-plastic state, and in this condition it is applied to coarse fabrics and used for heel stiffening, a purpose for which it is well adapted. Pure rubber is but little used except for artists' purposes.

In'dia-rub'ber, Ar-ti-fi'cial. A compound of chloride of sulphur, oil, and collodion. In its plastic state, it is easily molded, and hard and durable when well set. It can be made of any color, and is susceptible of a high polish. An English compound consists of linseed-oil oxydized on glass plates by repeatedly dipping the plates in the oil, and allowing it to dry each time. The film thus obtained is removed from the glass, crushed, and worked by the

Digitized by Google

mixing rolls, a small quantity of gum-shellac being added to give it the proper cohesion. The substance thus obtained is very much like rubber, and can also be vulcanized.

In'dia-rub'ber Bind'ing. A mode of binding books patented in England by Hancock, in which the usual operations of stitching, sawing, and hammering the back are dispensed with. The sheets are placed in a former to give the proper curvature to the back, and are then secured by packthread. They are next placed in a press, with their backs slightly projecting, and several coats of a solution of india-rubber applied, after which the bands are attached by means of the india-rubber solution, and the cover put on in the usual way.

In'dia-rub'ber Cloth. (*Fabric.*) Fabric covered with india-rubber. The latter is cleaned, triturated with sulphur, dissolved in benzine, or other solvent, and spread upon fabric by rolls.

In'dia-rub'ber Rolls. Rolls whereby rubber-cement, mixed with sulphur, and dissolved in benzine or other solvent, is spread upon fabric.

Some of these rolls spread the cement by a frictional action, the heated spreading-roll traveling faster than the cloth-carrying roll, and so grinding the gum into the cloth.

Gum mixed with paint is spread in a layer of the required thickness upon fabric, by rolls of even motion; and the rubber fabric is then cut into pieces according to pattern, for boot or shoe soles, etc.

In'dia-rub'ber Spring. The first known use of india-rubber for springs is in Lacy's English patent of 1825. He employed blocks of rubber with interposed plates of iron. Melville, 1844, obtained a patent for hollow spheres of rubber, enclosing air and separated by disks of wood or metal, the whole enclosed in iron cases. In 1845, Walker and Mills patented rubber bags filled with air and enclosed in a case for use as springs. Fuller, 1845, cylindrical rings of rubber having perforated disks between them, and a guide-rod passing through the whole. These had a tendency to swell out at the center under pressure, breaking or injuring the material. To remedy this defect, Spencer, 1852, 1853, formed the rubber rings of the shape which they would assume under pressure, and surrounded them with an annulus of iron. These have been used as buffer, bearing, and draw springs for railway-carriages with satisfactory results. (See also CAR-SPRING.) Eaton, 1856, employs alternate thin plates of rubber and metal, adapted for springs of great resistance and little flexibility. Hodge, 1852, patented a compound spring composed of a block of rubber inclosed in a two-part casing, the upper part surrounding the lower, and rising or falling according to the amount of compression of the rubber placed on each end of a steel spring. Scott, 1852, blocks of rubber placed over the center of a steel spring. Bridges, 1857, employs wooden instead of iron surrounding rings to confine the rubber blocks, and dispenses with the central rod. Fuller, above referred to, employs for suspension springs round cords, wound at a considerable tension around two metallic rollers or reels. During the Russian war, a number of mortar-boats were built by the British government, each carrying a 13-inch mortar. In order to diminish the shock occasioned by the recoil of such heavy ordnance on these small vessels, twenty very strong rubber rings were placed under each mortar-platform. These were tested by actual service at Sveaborg, in the Black Sea, and afterward in China, with very satisfactory results.

In'dia-rub'ber Thread. This is prepared by cutting a sheet into filaments, which are then stretched in a hot atmosphere or hot water; the process being several times repeated with alternate coolings. It is glazed by agitating with French chalk-powder.

In'di-ca'tor. A marking or recording instrument, or one which makes a visible sign by which the condition of the object or apparatus to which it is attached may be observed. The various uses to which indicators are applied may be suggested by the following: —

Door-indicator.	Station-indicator.
Leak-indicator.	Steam-indicator.
Leeway-indicator.	Street-indicator.
Shoal-indicator.	Tourists'-indicator.
Speed-indicator.	Weather-indicator.

Besides these compound forms, the term has also many other applications; as, —

The gradient post of a railway.

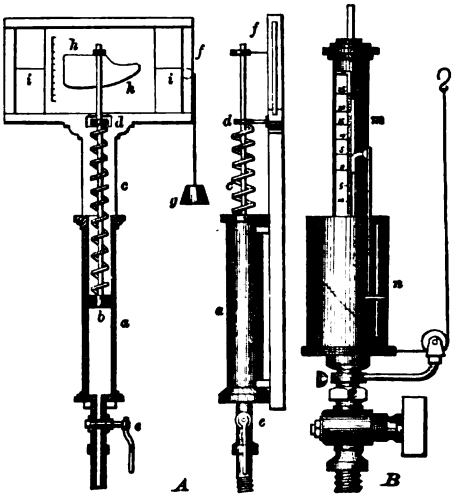
A gage in a blast furnace to indicate the proper hight of a charge.

The principal meaning of the word, however, concerns the instrument by which working steam records its pressure.

1. (*Steam-engine.*) An instrument which registers the relative amounts of steam pressure exerted on the piston at each portion of its stroke. It was invented by Watt.

Watt's indicator *A* consists of a cylinder *a* in which works a piston *b*, that is (when the cylinder

Fig. 2668.



Steam-Indicator.

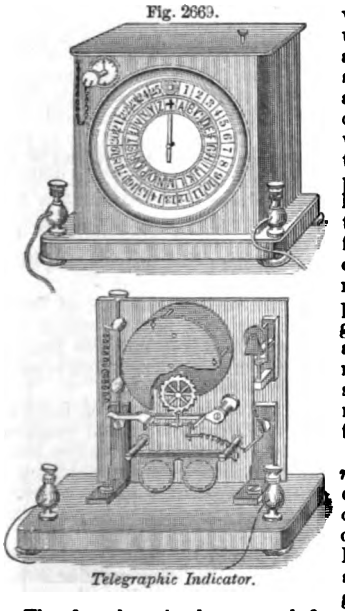
is not in communication with the steam-cylinder) maintained near the midlength of the indicator cylinder by the spiral spring *c*. The piston-rod works through a collar *d*, and has at its upper end a device for holding a pencil. Communication with the steam-cylinder is effected by the cock *e*, and when steam is admitted through this it causes the piston to rise, compressing the spring with a force equal to the excess of the steam pressure above that of the atmosphere. When a vacuum is produced by the condensation of the steam in the cylinder, a corresponding vacuum is formed in the indicator, causing the piston of the indicator to be forced down by a pressure equal to the excess of the atmospheric pressure over that of the uncondensed vapor in the cylinder. In order to register this, a small square movable frame *f* is placed at the upper end of the indicator, in which a card is inserted. One end of the frame is attached

Digitized by Google

by a cord to some movable part of the engine, and the other has attached a string and weight. When the piston rises, the card is drawn to the left, raising the weight *g*, which, when the piston descends, draws back the card to its first position. An alternate reciprocating motion of the card is thus kept up. Thus as the piston of the indicator rises and falls, its pencil traces on the card a line whose vertical ordinates represent the actual pressure, and whose length corresponds to the length of stroke of the piston. The *diagram* thus formed is shown at *h h*. All above the median line *i i* indicates the pressures on the piston, and all below it the vacuum, or the difference between the pressure of the uncondensed vapor and that of the atmosphere.

B (Fig. 2668) shows a modification of the above, which is provided with an upright graduated cylinder *m* surrounded by a larger cylinder *n*, upon which the registering paper is placed. This has a partial rotation back and forth by means of a cord connected to some part of the engine which has a reciprocating motion and a spring which restores it to its first position.

Fig. 2669.



Telegraphic Indicator.

2. (*Telegraphy.*) The dial and mechanism of a dial telegraph. Fig. 2669 shows Breguet's.

The face has the letters and figures arranged in two concentric circles. The motion of the hand is continuous in one direction, advancing one letter at each closing of the circuit. This movement is effected by clock-work driving a scape-wheel, the teeth of which are alternately engaged and released upon opening and closing the circuit, by means of a pawl operated intermediately from the armature of the electro-magnets.

3. (*Optics.*) A finger working in the field of a microscope to point out a special object within the field of view.

4. A dynamometer or power measurer.

In'di-ca'tor-card. A card containing a diagram drawn by the working steam by means of an INDICATOR (which see).

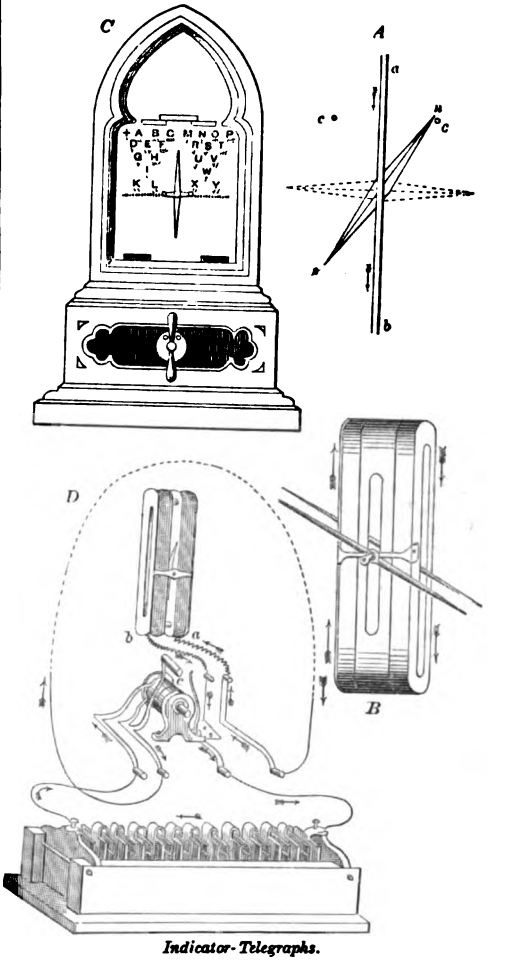
In'di-ca'tor-tel'e-graph. An electric telegraph in which the signals are given by the deflections of a magnetic needle.

It was about 1819 that Œrsted of Denmark made the discovery that if a magnetic needle, free to turn about its center, were placed near to and parallel with a wire, then, on causing an electric current to pass through this wire, the needle would be deflected to an angle proportioned to the force of the current.

In Fig. 2670, *A*, *a b* being the wire and *n s* the needle, the passage of a current in the direction of the arrow deflects the needle to the position indicated, the stops *c c* limiting its motions. When the direction of the current is changed, the *n* (north) pole of the needle is deflected in the other direction. By a preconcerted system, a given number of movements to right, left, or a certain number in alternate directions, a system of indications representing letters and numerals is obtained, as will be explained presently.

In practice, a pair of needles, rendered astatic (see ASTATIC NEEDLE), are used and placed in conjunction with a coil of wire, which multiplies the transmitted current so as to cause a much greater deflection than that due to the line current itself, as shown at *B*, which consists of a frame around which are wound several hundred feet of fine copper wire. The needles are mounted on the same axis, one within and one without the coil, and the outer one is exterior to the dial-plate of the telegraph.

Fig. 2670.



Indicator-Telegraphs.

Following the discovery of Œrsted, Ampère in 1820 suggested that the needle moved by the galvanic current should be used for conveying signals, and the idea was elaborated in lectures by Ritchie in 1830.

Baron Schilling, in Russia, in 1832, contrived a complicated instrument on this principle, in which a separate circuit and needle was employed for each

Digitized by Google

letter and numeral, 36 needles being employed, each being excited by a current of electricity as the occasion required.

Cooke and Wheatstone's indicator-telegraph, patented June 12, 1837, is the most prominent and best example of this class of instruments, and is generally used in England.

America and the continent of Europe employ the much superior system of Professor Morse, introduced about the same time.

C is a front and *D* a rear view of Wheatstone's instrument. In this the right and left hand terminals *a b* of the multiplier are each connected to the line-wire, which is, when a message is not being transmitted, thrown out of connection with the local battery.

The circuit is opened and closed by means of a drum *c*, at each end of which is a stout steel wire forming respectively the positive and negative poles of the battery; these wires, on turning the drum, are brought in contact with springs connected with the line-wire, by which either a positive or negative current is transmitted, causing the needle at the receiving station to be deflected to the right or left accordingly.

The letters of the alphabet and other signals are indicated by the number of beats made by the needle, some to the right and others to the left; thus "D" is represented by a beat to the right and one to the left. "L" requires four beats, in the following order, right, left, right, left, and so on for other letters.

The double-needle telegraph on the same principle is much more expeditious, and has been extensively employed in England, but requires two line-wires. See ELECTRO-MAGNETIC TELEGRAPH.

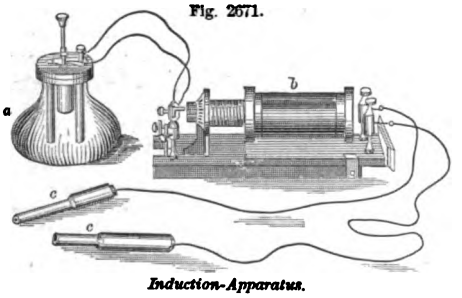
In-di-gom'e-ter. An instrument for ascertaining the strength of indigo.

In'di-go-mill. A four-sided iron cistern, cylindrical or rounded at bottom, resting upon gudgeons in a wooden frame. It has an iron lid with two leaves, between which works a rock-shaft receiving a vibratory motion from a crank, and imparting a swinging motion to a frame carrying six rollers, three on each side, which triturate the indigo to a fine paste; when sufficiently ground, the paste is drawn off by a stop-cock.

In-duc'tion. (*Electricity.*) That effect of an insulated electrified body which tends to produce an opposite electrical state in surrounding bodies.

In-duc'tion-coil. A compound coil by which voltaic or dynamic electricity is converted into static electricity or electricity of high tension. The discoveries of Faraday, Henry, Bequerel, and others led the way to the invention of the induction-coil, and it is believed that the first practically useful device

Fig. 2671.



Induction-Apparatus.

of the kind was contrived by the late Dr. Charles G. Page of Washington.

Ruhmkorff, of Paris, having made many instruments of the kind and contrived various improvements, the instrument is now very generally called by his name.

It consists essentially of an inner coil of coarse wire surrounding a core of soft iron rods, and connected with the poles of a voltaic battery. It is itself surrounded by, though insulated from, a coil of copper wire composed of a great number of convolutions, and connected with the discharging conductor. By opening and closing the circuit with great rapidity, which is effected by means of the AUTOMATIC CIRCUIT-BREAKER (which see), a nearly continuous current is produced. To intensify this, the return current from the primary coil produced by the disruption of the current is passed through a CONDENSER (which see); the effect may be increased by breaking the current under crude petroleum or other non-conducting medium.

The induction-coil is practically applied to many purposes in the arts, and in the treatment of diseases by electricity. Fig. 2671 is an instrument of this kind. The battery *a* consists of a single Grenetts cell, supplied with dilute sulphuric acid and bichromate of potash. One zinc and two carbon plates compose the elements, the former of which is lifted clear of the fluid when not in use. A vibrating spring opens and closes the circuit. *b* is the coil, and *c c* two dischargers, by means of which the current is directed to any part of the person.

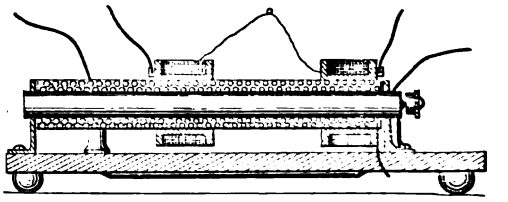
In the largest class of induction instruments, electricity of very high tension is produced.

One belonging to the Stevens Institute of Technology weighs 160 pounds; the primary wire is 200 feet and the secondary about 44½ miles in length. This projects a spark 21 inches in length and capable of penetrating glass three inches thick.

Another, at the Polytechnic Institute of London, has its primary wire 3,777 yards long, and weighing 145 pounds. The induction-wire is 150 miles long. This projects a spark 29 inches long, penetrating 5 inches of plate-glass. Its calorific effects are very intense, the most refractory substances, as platinum, being fused with ease.

In Kidder's induction-coil, the secondary helix or helixes are adjustable, so that they may be either concentrated at the central or neutral portion of the

Fig. 2672.



Induction-Coil.

primary coil or placed toward the poles, so as to vary the power of the induced currents. See Noad's "Inductorium."

Electrical machines of great power are now constructed on the induction principle.

In-duc'tion-pipe. (*Steam-engine.*) The pipe which leads the live steam to the cylinder.

In-duc'tion-valve. The valve which controls the entry-port for live steam to the cylinder of an engine.

In-duc-tom'e-ter. An instrument for ascertaining the force of electrical induction.

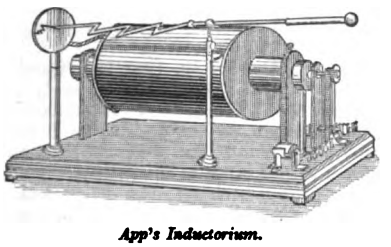
In-duc-to'ri-um. (*Electricity.*) Another name for the induction-coil as adapted for the display of

Digitized by Google

the electric spark. The instrument shown was constructed for the Royal Polytechnic Institution of London, and gave a spark 18 inches in length.

In Ritchie's instrument, the *secondary* consists of coils wound up into flat disks the thickness of the wire, and these are piled up against each other upon the primary coil, the separate coils being separated by thin disks of gutta-percha. The current is made to reverse from the center to the circumference and

Fig. 2673.



App's Inductorium.

conversely, to and fro, as many times as there are coils upon the core.

In-fe'ri-or Let'ter. Letters cast with their faces low down on the shank; as 4_b.

In-flect'ed Arch. 1. A reversed or inverted arch.

2. An arch, the curve of whose flanks is reversed near the crown, so as to terminate in an acute angle. (*e*, Fig. 305.)

In'gate. The aperture in a mold at which the metal enters. It then passes by *runners* to the spaces made vacant by the withdrawal of the pattern. The *ingate* is technically called the *tedge*, *gate*, *geat*, or *git*. The latter two are corruptions of *gate*.

In'got. A cast mass of steel from the crucible.

A cast mass of gold or silver, more or less pure, for *assaying*.

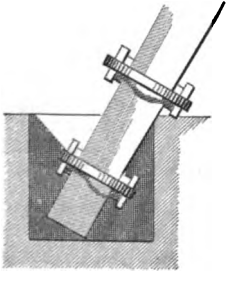
A cast block of gold, silver, or a properly proportioned alloy of either, for *coinage*, or for working into other forms, as watch-cases, etc.

The crude ingot of gold or silver, after being assayed and brought to the standard fineness (varying according to its purpose), is cast into *bars* ready for rolling, if for coin.

Gold and silver are run into *ingots* or *bars*.

A transposition of *ingot* made *nigot*, which passed into *nugget*.

Fig. 2674.



Ingot-Mold.

Iron is cast into *pigs*.

Steel is cast into *ingots*.

Copper at one stage into *bricks*, at another into *pigs*.

Tin is run into *blocks*.

Silver from the subliming furnace is in porous blocks, called *bricks*.

The cast, flat lump of gold for the goldbeater weighs two ounces, and is $\frac{3}{4}$ of an inch broad.

In'got-mold. A flask in which metal is cast into blocks.

The *ingot-mold* for cast-steel is made of cast-iron, and of a shape and size to suit the form and volume of the steel bar or plate required. The mold is in two parts, separating longitudinally, and united for use by collar-clamps and wedges. The interior of the mold is smoked by the fumes of burning pitch, so as to give it a carbonaceous coating, the purpose of which is to prevent the adherence of the cast-steel thereto.

The operation of pouring the metal is called *teaming;* the ingot is turned out while yet red-hot, and is rolled into the shape required.

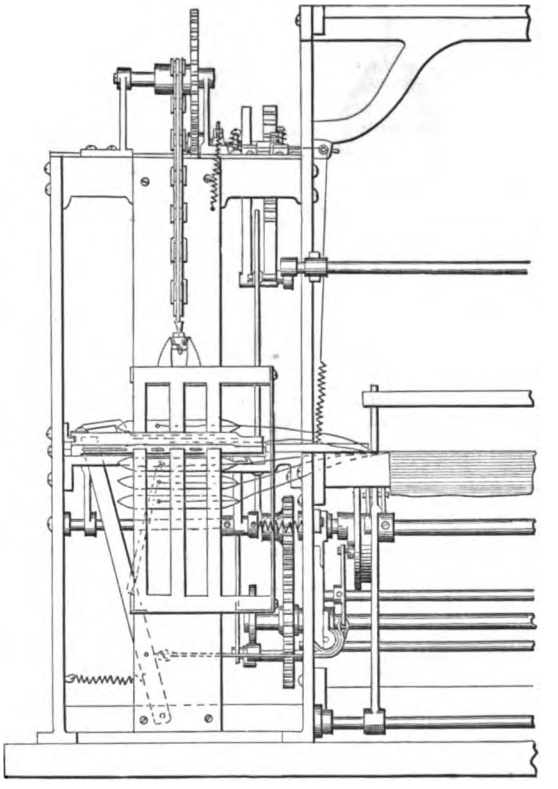
In'grain. A yarn or fabric dyed with fast colors before manufacture.

In'grain Car'pet. A carpet manufactured from wool or woolen dyed *in the grain* (before manufacture). These carpets are known as *Scotch* or *Kidderminster*, from the country and town where they are so extensively manufactured; also as *two-ply* or *three-ply*, according to the number of webs of which the fabric is composed. See TWO-PLY CARPET.

In'grain-car'pet Loom. A loom in which two or more shuttles, one for the ground and the other for the figure, are employed.

In Bigelow's (Fig. 2675) the two, after being thrown, are received in horizontal boxes on each side of the frame, and a third series, containing the different colored yarns producing the pattern, are placed in a set of vertically arranged boxes; all the shuttles are actuated by the same picker-staves; and the figure shuttles are raised and lowered as required by pinions having a reciprocating rotary motion on a shaft, their presentation being determined by a pattern-wheel, having movable cam-surfaces on the

Fig. 2675.



Ingrain-Carpet Loom.

Digitized by Google

shaft; one vibrating cam moves the lay forward to beat up the cloth, and another moves it backward, while a shuttle is thrown.

In-hal'er. 1. An apparatus to filter and warm the air respired by persons with delicate lungs, or by those subjected to a deleterious atmosphere.

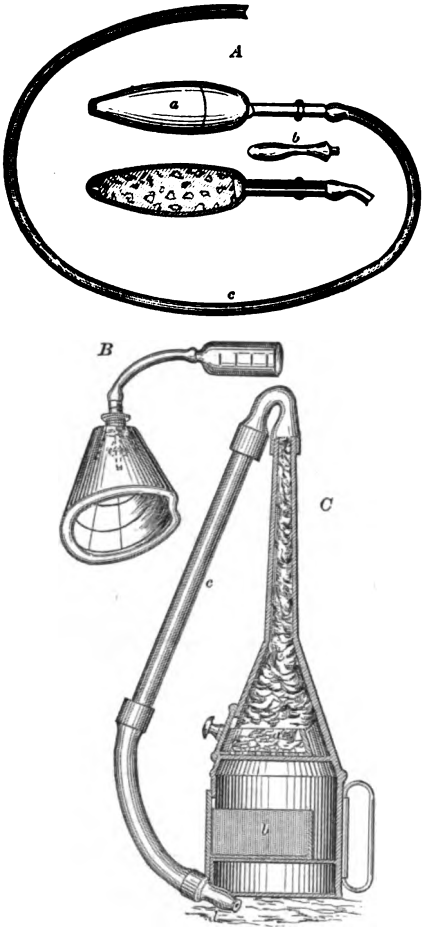
In apparatus for consumptives, it consists of a replicated wire-gauze tissue. A *respirator*.

2. For cutlers and others subjected to an atmosphere of iron dust, it is a magnetic tissue which arrests the dust.

3. An instrument for inhaling or inwardly applying medicated vapors or anæsthetic agents.

4. An apparatus to enable a fireman, miner, or diver to work in a poisonous or heated atmosphere,

Fig. 2676.



Inhalers.

or in water, carrying with him a supply of vital air. See DIVING.

Dr. Priestley's letter, speaking of "Gaseous oxyd of Septon" (*dephlogisticated nitrous air*), was addressed to one of the editors of the "New York Medical Repository," and was republished in the "London Monthly Magazine," June 1, 1800.

Chloroform was discovered by Guthrie, Souberain, or Liebig, about 1831, but its valuable properties as an anæsthetic were not appreciated until 1847. Dr. Morton of Boston, and Professor Simpson of Edinborough, discovered its applicability to this purpose almost simultaneously in 1847. See ANÆSTHETIC APPARATUS.

Morton's inhalation apparatus, November 13, 1847, has a chamber to hold the sponge, and two lateral openings through which respectively enter the atmospheric air and pass out the air impregnated with the vapor of the anæsthetic agent. These openings are valved to prevent reflux of air, and a chamber above contains a reserve of liquid, which is admitted to the sponge-chamber by moving a valve, at such times as may become necessary.

Roper's cup, October 10, 1848, is a vessel to hold sulphuric ether, and the rim fits closely over the mouth and nose. The body of the instrument then inclines downward, and an opening in front admits air, which passes into the ether-chamber, and then to the mouth and lungs of the patient.

Dr. Buttles's inhaler (*A*, Fig. 2676) consists of a bulb *a* of hard rubber in two sections, and containing a sponge which is charged with the required medicament. It has an opening at one end, which is closed by a stopple *b*, and to the other end is attached a flexible tube *c*. For use, the bulb is introduced into the mouth, the open end nearly touching the veil of the palate, and the air inhaled through the flexible tube becoming charged with the medicament in its passage through the sponge. It is also adapted for nasal inhalation, one nostril being closed by the finger while inspiration is performed through the other.

This inhaler may be conveniently carried in the pocket.

The inhaler *B* (Fig. 2676) consists of a light conical frame-work of wire, having a soft cushion at the base and adapted to fit over the nose and chin, but not covering the eyes. A double cone of flannel is slipped upon this, over which is screwed a short tube having three branches equidistant from each other. This is covered by a cone of tin or other material impervious to ether, maintained in place by a nut screwing over the tube. For use, an india-rubber tube is drawn over the tube above mentioned, the other end of the rubber tube being attached to the neck of a bottle containing ether.

Tichenor's inhaler (*C*, Fig. 2676) is made of sheet metal in the form of a cylinder, surmounted by an inverted funnel. It contains an upper drawer *a* and a lower drawer *b*, in the former of which is placed the medicinal substance to be vaporized, and in the latter live coals or a piece of hot iron to effect this result. The top is connected with a tube *c*, the ends of which are of vulcanized rubber, and is provided with a mouth-piece *d*. The drawer *b* is left partially open during the generation of the vapor, admitting air which, passing through the perforated bottom of the drawer *a*, causes a draft through the funnel and serves to dilute the medicated vapor. This apparatus is also designed for anal and vaginal applications, the drawer *b* being closed and a hand-bellows attached to the tube employed to cause a draft.

The nitrous-oxide inhaler has two valves. One opens during the inspiration to admit gas from the reservoir to the lungs, and closes during expiration. The other valve opens during expiration to allow the effete air to pass off, and prevent its mixing with the contents of the reservoir. Thus a pure article is breathed at each expansion of the lungs.

Pilatre des Roziers invented an inhaler for enabling persons to enter places filled with deleterious gases; it consisted of a bag or case of leather or metal

Digitized by Google

charged with air under pressure; it was carried on the back, and provided with a flexible tube reaching around to the mouth of the bearer, and provided with an inwardly and an outwardly opening valve for inspiration and expiration. The nostrils were closed by a spring clamping the nose.

Galibert's apparatus is very similar to the above. Rouquayrol's apparatus, Fig. 2677, consists of a sheet-iron reservoir capable of bearing a pressure of 25 to 40 atmospheres; air is forced into it by a pump, the piston of which is fixed and the cylinder movable. Above is a bellows-like arrangement, which transmits the air to the tube leading to the nostrils of the operator, under merely the ordinary atmospheric pressure. A small two-leaved valve of india-rubber, kept closed by the external pressure of the air, opens to allow the escape of the air respired. This apparatus is carried on the back, like a soldier's knapsack. It is also used in submarine explorations.

Fig. 2677.

Rouquayrol's Apparatus.

In'haul. (*Nautical.*) A rope or purchase for rigging-in the jib-boom, studding-sail, or other spar.

In-jec'tion-cock. (*Steam-engine.*) The cock which closes the injection-pipe by which cold water is admitted to the cistern of the condenser.

In-jec'tion-con-dens'er. A cast-iron vessel of any convenient shape, and strong enough to bear the atmospheric pressure from without, in which the exhaust steam from the cylinder is condensed by a shower of cold water. The capacity of the condenser in Watt's original engines was ⅛ that of the cylinder; but, according to present practice, it ranges from ¼ to ½ of that of the cylinder, and sometimes even more. See CONDENSER; AIR-PUMP, etc.

See Burgh, "On Condensation of Steam" (London, 1871).

In-jec'tion-en'gine. (*Steam-engine.*) One in which the steam is condensed by cold water injected into the condenser. See CORNISH ENGINE; ATMOSPHERIC ENGINE.

In-jec'tion-pipe. (*Steam-engine.*) The pipe through which the injection water passes to the cistern of the condenser. In marine engines, the injection-pipe is open to the sea by a pipe which passes through the bottom of the vessel. See AIR-PUMP; CORNISH ENGINE.

In-jec'tion-syr'inge. (*Surgical.*) A syringe for administering douches or medicines.

c is the stand-pipe which rests in the bowl; *a* is the elastic air-bulb; *d*, the pipe; *e*, the nozzle.

f is Roosa's instrument for treating diseases of the middle ear. See Fig. 1814, p. 769.

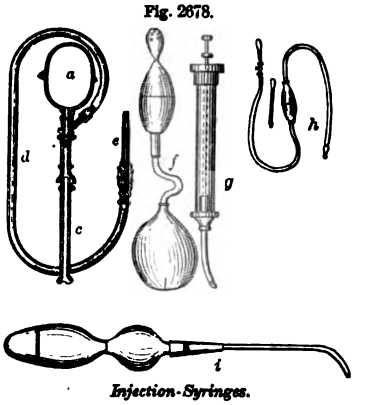
g is a self-injecting elastic syringe.

h is Tiemann's transfusion syringe.

i is an insufflator for blowing powder into the larynx or otherwhere. See INSUFFLATOR.

In-jec'tion-valve. (*Steam-engine.*) The one which governs the entrance of water into the condenser from the sea, river, or well.

Fig. 2678.



Injection-Syringes.

The area of the injection-valve of a marine steam-engine is stated at one square inch for every 10-horse power. This is said to be ample allowance in all cases, and is more than necessary when the injection water has a temperature of 52° Fah. The average temperature of the Mediterranean is about 65°; the Atlantic Ocean, at 20° of latitude, about 75°; and at the equator, about 82° Fah.

In-ject'or. A device for injecting a supply of feed-water into the body of a steam-boiler.

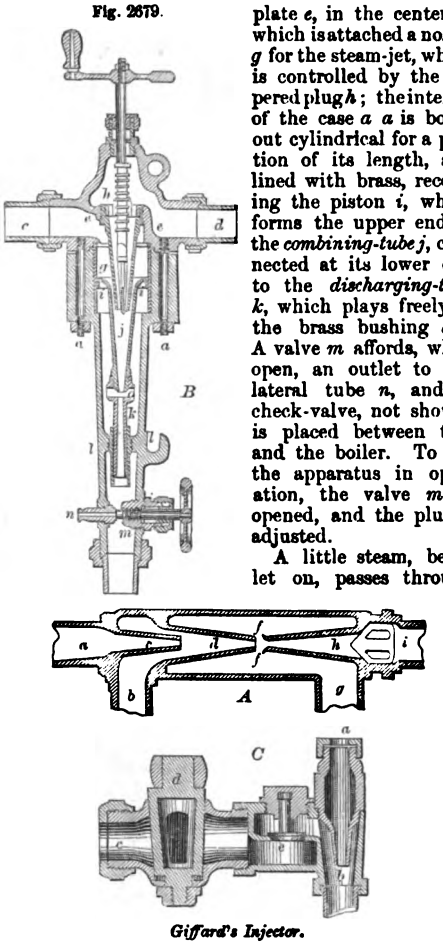
In Giffard's injector this is effected by the pressure and condensation of steam from the boiler itself. Fig. 2679, *A*, illustrates the operation of this apparatus. Steam escaping from the boiler through the pipe *a* is compelled to pass through the contracted nozzle *c*, by which its velocity is greatly increased. The feed-water from the pipe *b* is drawn into an annular space surrounding the nozzle *c*, and, mingling with the condensed steam, is driven through the pipe *h* and valve *i* into the boiler. Excess of steam or water, from want of proper adjustment, escapes through the outlet *f f g*.

The principle is as follows: Under a given pressure the velocity of escaping steam is much greater than that of the water which would be ejected were a hole opened in the boiler below the water-line. At a pressure of 90 pounds to the square inch, the excess of velocity of the steam is about in the proportion of 9 to 1. As the escaping steam, in being condensed, loses none of its velocity, except that due to the friction of the pipes through which it passes, it consequently, after condensation, has a penetrating force about nine times greater than the resisting force of the water in the boiler. At the moment of condensation it imparts its momentum to the water by which it is condensed, and with which it mingles. For instance, 1,700 cubic inches of steam on being condensed into one cubic inch of water imparts sufficient momentum to eight cubic inches of the water by which it is condensed to exactly balance the pressure of water in the boiler. In this case the opposing forces are in equilibrium; but combined with any less quantity of water, say seven inches, the momentum will more than suffice to overcome the resistance of the water in the boiler, and the mingled condensed steam and feed-water will force its way into the boiler, if a properly constructed entrance be provided for it.

Fig. 2679, *B*, shows Sellers' improved injector on the Giffard principle. *a a* is the outer casing in two parts united by bolts. It has two inlets, one *c* for water, and the other *d* for steam, separated by a

Digitized by Google

Fig. 2679.



Giffard's Injector.

plate *e*, in the center of which is attached a nozzle *g* for the steam-jet, which is controlled by the tapered plug *h*; the interior of the case *a a* is bored out cylindrical for a portion of its length, and lined with brass, receiving the piston *i*, which forms the upper end of the *combining-tube j*, connected at its lower end to the *discharging-tube k*, which plays freely in the brass bushing *l l*. A valve *m* affords, when open, an outlet to the lateral tube *n*, and a check-valve, not shown, is placed between this and the boiler. To put the apparatus in operation, the valve *m* is opened, and the plug *h* adjusted.

A little steam, being let on, passes through the small aperture in the steam-plug, creating a vacuum and causing the water to rise, when it is driven through the tubes *j k*, escaping at *n*. The plug *h* is then raised, increasing the flow of steam, and the valve *m* closed.

The action is as follows: The steam passing into *j* is condensed by the water from the water-supply tube, and the combined jet is driven through the discharge-tube *k*, and thence into the boiler.

If the water supply is in excess, a portion escapes by the opening *o* between the combining and delivery tubes, elevating the piston *i*, and contracting the annular space through which the water enters the combining-tube and limiting the supply. If the water supply is deficient, the velocity of the steam-jet is increased, a partial vacuum is formed in the chamber, and the piston *i* descends, enlarging the area of the water-supply space and permitting an increased flow. The apparatus is thus rendered self-regulating.

The injector *C* is used in the Westinghouse air-brake as an air-pump; the steam entering at *a*, and passing out as a jet at *b*, induces a current of air through the pipe *c* which leads from the cylinder beneath the car. (See BRAKE.) In this cylinder is the piston, which is mechanically connected to and works the brake-bars. *d* is a faucet which shuts off connection between the injector and brake-cylinder. *e* is an automatic valve which prevents reflux air through the pipe.

The injector has many other uses in the arts and manufactures: —

As an air and vapor pump it is applied to vacuum-pans, condensers of steam-engines, aspirators (by Bunsen), pneumatic dispatch-tubes (Siemen), etc. The well-known locomotive blast-pipe was an early application of the principle of the injector. (See LOCOMOTIVE; NOZZLE.) The action of these pipes was afterwards explained by Zeuner, and further results are due to Prüsman.

Gurney's steam-ventilator acted by means of steam passing through one pipe and sucking air through another connected with it. This simple apparatus was afterwards employed by Nagel and Kaemp in centrifugal pumps. Besides these may be mentioned Thompson's pump, the water-bellows, and Danchell's steam-manometer.

Ink. 1. A colored liquid or viscous material used in writing or printing.

The ancient ink was thick, and so is the modern Chinese. Demosthenes reproached Æschines with laboring in the grinding of ink as painters do in preparing colors. There is a difference between a *paint* and a *dye*, though the distinction is very imperfectly made out in customary language. A paint is smeared over an object, a dye colors or stains it. Some inks are of one kind and some of the other. The essential characteristics of the best ink are: limpidity, permanence, distinctness. The first enables it to flow easily and avoids clogging the pen. The second prevents its fading and becoming indistinct. The third makes it readily legible, both to the eye in following the motions of the pen, and to the eyes of readers subsequently.

An ink was found in an inkstand at Herculaneum. Some ancient manuscripts show the ink in relief when held to the light, and some have evidently been corroded by the ink.

Black ink is a solution of tanno-gallate of iron suspended in gum-arabic water. Logwood adds to the color. Take bruised galls, 6 ounces; gum-arabic, 4 ounces; green vitriol, 4 ounces; soft water, 6 pints. Boil the galls in the water, add the other ingredients; keep in a bottle, shake occasionally, and in two months' time decant into bottles and cork.

A drop or two of creosote or essential oil of cloves will prevent molding, or, as Dr. Gale remarked to an astounded Indianian, "will prevent the deposition of the ova of infusoria animalculæ."

He might have added, "and the sporadic growth of thallogenic cryptogams."

Such would probably be fatal to the fungi; the mere definition settled our brother from Indiana.

The addition of sugar to ink prevents sudden drying and makes *copying ink*.

Japan ink: Ribaucourt's recipe: aleppo galls, 8 ounces; logwood, 4 ounces; sulphate of iron, 4 ounces; gum-arabic, 3 ounces; sulphate of copper, 1 ounce; sugar candy, 1 ounce.

The galls and logwood to be boiled in twelve pounds of soft water until reduced to six pounds. Strain, and add the other ingredients. The ink dries with a gloss; hence its name.

Desormeaux recommends that the sulphate of iron be calcined to whiteness; coarse brown sugar instead of sugar candy; ¼ ounce of acetate of copper instead of 1 ounce of the sulphate; and agitation twice a day for two weeks before decanting and bottling.

Indelible ink. The addition of lampblack to ink will fortify it against the discharge of its colors by hydrochloric acid.

Digitized by Google

Close's recipe: copal, 50 grains; oil of lavender, 400 grains; lampblack, 5 grains; indigo, 1 grain. Dissolve the copal in the oil by heat, and then add the coloring matter. Thin with oil of turpentine.

Sheldrake's recipe is a varnish, and is used for tombstones and marble: asphaltum or pitch, oil of turpentine, amber varnish, lampblack.

Red ink is a solution of alum colored with Brazil-wood; or an ammoniacal solution of cochineal.

An indestructible red ink, or rather paint, consists of copal, 2 ounces; oil of lavender, 14 ounces; vermilion, 7 ounces.

Blue ink: sulphate of indigo dissolved in water to the desired tint.

Yellow ink: French berries, 8 ounces; water, 1 quart; alum, a small quantity.

Green ink: a mixture of blue and yellow.

Orange ink: a mixture of red and yellow.

Purple ink: a mixture of red and blue.

Brown ink: a mixture of black and yellow.

Sympathetic ink is an ink which is invisible till the writing is subjected to a subsequent operation, such as warming, exposing to sunlight or to a chemical reaction.

The ancients were acquainted with several modes. Ovid indiscreetly advises maidens to write with new milk. This, when dried, may be rendered visible by rubbing ashes upon it. Pliny suggests the milky juices of certain plants.

Modern chemistry has given us a number of recipes. Writing in the following solutions, subsequently dried, will be rendered visible by the means cited, developing certain colors.

Ink.	Treatment.	Color developed.
Acetate of lead.	Liver of sulphur.	Brown.
Gold in aqua regia.	Tin in aqua regia.	Purple.
Infusion of galls.	Sulphate of iron.	Black.
Dilute sulphuric acid.	Heat.	Black.
Cobalt in dilute aqua regia.	Heat.	Green.
Precipitated oxide of cobalt in acetic acid and salt	Heat.	Blue.
Lemon juice.	Heat.	Brown.

Marking-ink is an aqueous solution of lunar caustic thickened with sap green and gum. It is written on a surface prepared by a weak solution of carbonate of soda and gum-arabic.

A *marking-ink* requiring no preparation of the surface is made of nitrate of silver, 1 ounce; bi-tartrate of potash, 1 ounce; solution of ammonia, 4 ounces; archil, ½ ounce; honey, 3 drachms; tragacanth powder, 1½ drachms. When written, pass a hot iron over it or hold to the fire.

Marking-inks formed of a silver compound may be discharged by a solution of cyanide of potassium or a solution of corrosive sublimate, 1; sal-ammonia, 1; water, 100.

Lithographic ink for writing on stones, or for transferring autographically from paper: dry soap, 100; white wax, 100; mutton suet, 30; shellac, 50; mastic, 50; lampblack, 30. Incorporate with heat; pour on an oiled plate; cut into sticks, and use like India-ink.

Lithographic printing-ink resembles that for letterpress, but is ground up with burned linseed-oil, known as *lithographic varnish*.

Copperplate printing-ink is similar to that for letterpress, but is made of ivory-black or other fine quality.

Printing-ink is a smooth, jet-black oil paint, made of boiled linseed-oil, rosin-oil, or nut-oil, and lampblack; soap and rosin are sometimes added.

Red and other colored printing-inks are made of linseed-oil boiled into a varnish, and with pigments of the required colors. Vermilion, Prussian blue, indigo, orpiment, chrome, red and orange lead, verdigris, etc. See Ringwalt's "Encyclopedia of Printing," page 226.

India-ink is a compound of lampblack and size; formerly prepared from the pigment of the cuttle-fish.

Ink for zinc plant-labels: chloride of platinum, 100 grains, in a pint of water; add mucilage and lampblack.

Or: sal ammonia, 1 drachm; verdigris, 1 drachm; lampblack, ½ drachm; water, 10 drachms. Mix.

Fire-proof ink for use in writing or printing on incombustible paper consists of: powdered graphite, 22 drachms; copal or other resinous gum, 12 grains; sulphate of iron, 2 drachms; tincture of nut-galls, 2 drachms; and sulphate of indigo, 8 drachms. These materials are mixed together and boiled in water. This ink, which, besides being fire-proof, is said to be insoluble in water, under ordinary circumstances is black; but when colored inks are desired, the graphite is replaced by an earthy or mineral pigment of the desired color.

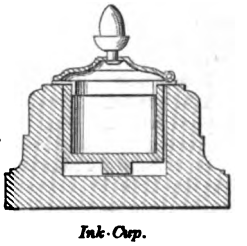
2. (*Machinery.*) The socket of a mill spindle. See STEP.

Ink-bench. (*Printing.*) An inking-table.

Ink-block. (*Printing.*) A block on which the ink is spread to be taken up by the balls or rollers.

Ink-cup. A dip-cup for ink. In the example, it is of rubber or glass in a wooden socket, and has a metallic flange and cup.

Fig. 2680.



Ink-Cup.

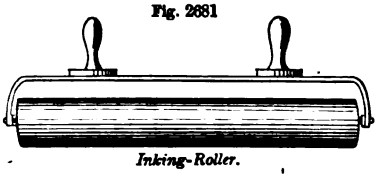
Ink-cyl'in-der. (*Printing.*) A cylinder rotating in the ink-fountain to bring the ink in contact with the *ductor* or fountain-roller.

Ink-foun'tain. (*Printing.*) The ink-reservoir of a printing-press from which the ink is taken by an ink-roller and passed to the *ductor*, or the distributing-roller.

Ink'ing-ap'pa-ra'tus. Different forms of apparatus have been adapted to different presses, and some of them are peculiar to the kinds. See list on page 226, Ringwalt's "Encyclopedia of Printing."

Ink'ing-roll'er. (*Printing.*) A roller which receives the ink from the inking-table and transfers it to the type in hand-press work. In power-presses, several rollers are employed, which are fed with ink

Fig. 2681



Inking-Roller.

from a trough, distributing it and transferring it to the inking-roller.

The composition of glue and molasses was invented by Donkin and Bacon (English patent, 1813). It is stated to have been previously used by one Edward Dyas of Madeley, Shropshire, England, who was indebted to an accidental overturning of his glue-pot to the suggestion of using the lump of semi-hardened glue.

Francis and Letmate's patent composition, June 21, 1864, consists of glue, 14 pounds; glycerine, 28

Digitized by Google

pounds; castor-oil, 2¼ pounds; borax, 3 ounces; ammonia, 2 ounces; sugar, 7 pounds.

The endwise motion of the ink-distributing rollers is in the English patent of Professor Cowper, 1818.

The diagonal arrangement of the inking-roller, to give it a *relatively* endwise motion to the inking-table, is described in Applegath's English patent, 1823.

Ink'ing-ta'ble. (*Printing.*) A table upon which ink is spread to be taken up by the inking-roller.

The combination of inking-table, trough, and hand-roller was invented by Professor Cowper, and was described in his English patent, 1818.

In his printing-machine, the inking-table passed back and forth under rollers which received an end motion at the same time by means of an indentation along the edge of the table acting upon a frame in which the rollers were mounted.

In Applegath's English patent, 1823, the rollers are placed diagonally across the table and receive an end motion thereby.

Ink'ing-trough. The reservoir of ink from which the inking-roller is supplied.

In'kle. A broad linen tape. *Wrought* spinel. Spinel is bleached yarn for the manufacture of the tape, and is known as *unwrought inkle.*

Ink-print'ing Pro'cess. (*Photography.*) A process by which positive prints are obtained in common writing-ink. Immerse the paper in a solution of bichromate of potassa, in the dark. Expose under a negative. The picture will be brown on a yellow ground. Wash to remove the undecomposed chromium salt. Immerse in a weak solution of protosulphate of iron, wash; the iron salt will adhere to the image or mordant. Immerse in tannic acid; the picture blackens by the formation of tannate of iron. Wash and dry.

Ink-slice. A paddle for handling ink.

Ink'stand. A cup or bottle, from which ink is dipped with the pen.

Among the varieties may be cited: —

A, a fountain inkstand in which ink is raised in the dip-hole by depressing the piston in the reservoir. In a modified form a porcelain block is suspended in the ink and forces ink into the dip-cup by displacement.

B has an elastic caoutchouc ink-cup in a wooden case. The screwing down of the cover raises ink in the neck.

C. The raising of the lid elevates a little pan of ink to a convenient position for dipping.

D is a fountain inkstand with an overflow chamber closed by a plug.

E is a globular fountain inkstand, movable in a socket.

F is the ordinary fountain inkstand with metallic base, and pen-rack.

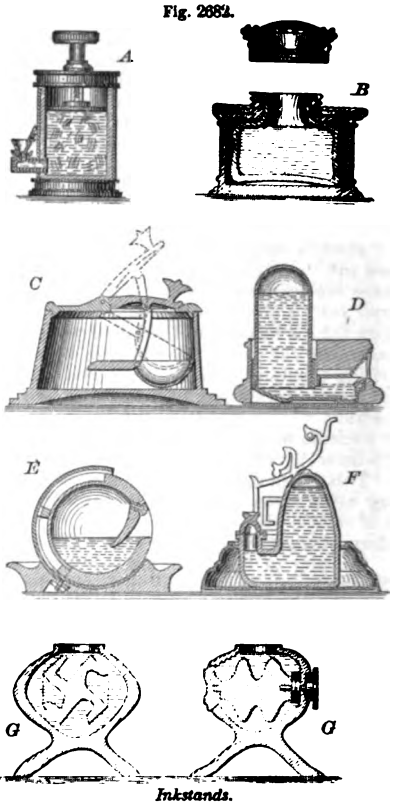
G G are two views of an inkstand having a glass disk containing four cups; rotation in one direction brings a cup of ink to be dipped from; in the other direction brings a solid portion of the disk to the aperture, and protects the ink from dust and evaporation.

The inkstands of the ancient Egyptians were of wood, porcelain, or other materials. Specimens are in Dr. Abbott's collection. They contain places for the red and black pigments, and also for the reed pens.

The inkstands of the Romans were round, square, or hexagonal; and single or double, the latter for red and black inks. A number were found at Pompeii.

The invertible inkstand is first shown in the English patent, No. 3407, November 25, 1869. It has a supplemental chamber and funnel above the usual center dip reservoir, to catch any ink which may pass out of the lower one in inverting. The present usual form is a center dip reservoir which latter has a lateral capacity sufficient to contain the contents of the dip-basin when tipped on its side or inverted.

Fig. 2682.



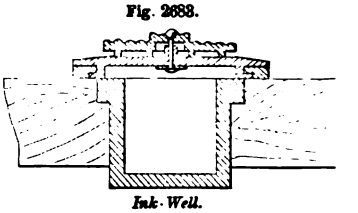
Inkstands.

Ink-sur'face. (*Printing.*) The surface on which ink is distributed in a cylinder-press.

Ink-ta'ble. A flat-topped table on which ink is brayed or mulled ready for the inking-roller.

Ink-well. An ink-cup adapted to occupy a hole in a desk, its top letting down flush with the top of the desk, or nearly so.

Fig. 2683.



Ink-Well.

In'laid-work. That in which one material is sunk into a hollowing in the surface of another, the two making an even face. See BUHL; REISNER-WORK; MARQUETRY; PARQUETRY; MOSAIC, etc.

In-lay'ing. A species of ornamentation in which choice woods, metal, ivory, mother-of-pearl, etc., are inserted within portions of groundwork which are sunken to receive them, thus forming a sort of mosaic.

We find specimens of inlaying of metals in the articles recovered from ancient Babylon.

Overlaying was practiced by the same people.

Herodotus states that "Glaucus the Chian" was

Digitized by Google

"the man who invented the art of inlaying steel." The salver made by Glaucus was offered by Alyattes the Lydian at the oracle of Delphi. It is described by Athenæus as "covered with representations of plants and animals." Alyattes was the father of Crœsus, who reigned till defeated by Cyrus, 556 B. C.

Under this head we may fairly refer to the Taj at Agra, the most beautiful building in the world. It is thus described by Sir Charles Dilke: —

"On the river bank [the Jumna], a mile from Akbar's palace, in the center of a vast garden entered through the noblest gateways in the world, stands the Taj Mahal, a terrace rising in dazzling whiteness from a black mass of cypresses, and bearing four lofty and delicate minars, and the central pile that gleams like an alp against the deep blue sky, — minars, temple, tomb, all of spotless marble and faultless shape. Its Persian builders named the Taj 'the palace floating in the air.'

"Out of the fierce heat and blazing sunlight you enter into chill and darkness, but soon begin to see the hollow dome growing into form above your head, and the tomb itself, that of Noor Mahal, the favorite queen of Shah Jehan, before you, and beside it her husband's humbler grave. Though within and without the Taj is white, still here you will find the walls profusely jeweled, and the purity retained. Flowers are pictured on every block in mosaic of cinnamon-stone, carnelian, turquoise, emerald, and amethyst; the corridors contain the whole Koran, inlaid in jet-black stone; yet the interior, as a whole, exceeds in chastity the spotlessness of the outer dome. Oriental, it is not barbaric. . . . . In a Persian manuscript there still remains a catalogue of the prices of the gems made use of in the building of the Taj, and of the places from which they came. Among those named are coral from Arabia, sapphires from Moldavia, amethysts from Persia, crystal from China, turquoises from Thibet, diamonds from Bundlecund, and lapis lazuli from Ceylon. The master masons were of Constantinople and Bagdad."

The varieties of inlaid work are numerous, and some of them very beautiful, bringing into use small fragments of valuable material that could hardly be applied to any other purpose. The principal varieties consist of *marquetrie*, in which woods of a variety of tints are inlaid in the form of flowers and other ornamental devices.

Buhl, wherein metals are inlaid upon a ground of ebony or tortoise-shell. The German cabinets made of ebony, and inlaid with precious stones or various woods and metals, constitute a species of this kind of work.

Mosaic inlaying, composed of extremely small pieces. The Hindoos make very beautiful boxes in this style. At the London exhibition in 1851 a table produced in Spain was shown, composed of three millions of pieces. Many Chinese and Japanese works of bijouterie are also of this class.

Parquetrie is a species of marquetrie on a bolder scale, applied chiefly to decorating floors, woods of different colors being cut to pattern and inlaid.

Pietra dura, consisting of certain kinds of hard stone, such as agate, jasper, chalcedony, carnelian, and lapis lazuli, inlaid in slabs of marble, generally black.

The marble is worked to a thickness not much exceeding one eighth of an inch, the design is drawn upon this, and is cut out with a fine saw and a file. The hard stones, worked into the required pattern by the usual modes of gem cutting, are accurately fitted into the spaces thus prepared, in a polished and finished state. After the whole is thus prepared, it is fixed as a veneer to a thicker slab.

Tarsia. This was formerly much practiced in Italy during the Middle Ages, and is now carried on in France and elsewhere. It is executed in woods of different shades, the figures comprising flowers, birds, and colored ornaments; the various parts being cut out to the required figure are then placed according to the design and fixed on paper; afterwards they are applied like veneers to a piece of furniture; being mounted, they are cleaned off and slightly polished, and the finer lines then engraved.

In-lay'ing-saw. A saw used in piercing stuff for buhl-work. See BUHL-SAW.

In'let. An opening into a drain or culvert.

In'ner-form. (*Printing.*) The form beginning with the second page of a sheet usually worked off first. In a quarto, it contains pages 2, 3, 6, 7.

In'ner-post. (*Shipbuilding.*) A piece brought in at the fore-side of the main-post, and generally continued as high as the wing-transom to seat the other transoms upon.

In'nings. (*Hydraulic Engineering.*) Lands recovered from the sea.

In-quar-ta'tion. (*Metallurgy.*) See QUARTATION.

In'sect-de-stroy'er. A device for killing noxious insects.

By *fumigation;* a bellows which drives poisonous fumes or vapors, such as those from sulphur, upon insects or plants.

By *dusting* sulphur upon them by means of a bellows and tube.

By *steam-jets.*

By *atomizers* which distribute coal-oil or turpentine in a fine spray.

By a *lamp*, which attracts nocturnal insects to singe their wings or allure them to a pan of water.

By *wire cages*, which imprison moths and worms which seek access to beehives. These are *traps.*

In'sect-trap. A device to catch insects upon or approaching an object.

Traps are set upon trees to catch the curculio. Such are frequently merely circular troughs around the stem. In some countries it is necessary to let the legs of tables, cupboards, and bedsteads stand in cups of water to prevent access of ants.

The moth-trap for beehives is a familiar instance, and consists of a wire cage which arrests them; or a lure to a box or pan, out of which they cannot get; or viscous smear which imprisons them; or a light which clips their wings.

In-sert'a-ble-tooth Saw. One with removable teeth. See SAW-TOOTH.

In-ser'tum-o'pus. A wall in which the stones are small and unhewn, similar to rubble-work. See MASONRY.

In'set. (*Bookbinding.*) Same as *offcut.* A certain portion of the printed sheet in 12mo, 24mo, etc., which is *cut off* before folding and set into the middle of the folded sheet, to complete the succession of paging.

In'shave. (*Coopering.*) A jointer having a convex-edged bit, on which the inner faces of staves are dressed.

In'side-cal'i-pers. A calipers for measuring bores and inside diameters of tubes. See CALIPERS.

In'side-cyl'in-der. (*Steam-engine.*) A cylinder placed in the smoke-box of a locomotive, to keep it warm; preventing the radiation of heat incident to the customary *outside* exposure.

In'side-fram'ing. (*Steam.*) *a.* The frame of one form of English locomotives, in which the wheels and driving-gear are inside of the main frame.

b. The stays of a locomotive-engine, that rest on the axles. The English practice is to have the

Digitized by Google

framing *outside* of the cylinders, the connecting-rods of the engines passing to cranks on the axles.

In'side-gear. (*Steam-engine.*) The English arrangement in locomotives of the pitmans and cranks inside the frame, in contradistinction to the American practice of connecting the cross-heads of the engines by pitmans to wrists on the outside of the driving-wheels.

In'side-screw. A hollow screw; one having its thread on the inside.

In'side Screw-tool. (*Lathe.*) A hook-shaped tool for threading interior surfaces while revolving in a lathe. A form of *chaser*. See Fig. 1256.

In'side-tin. (*Bookbinding.*) A plate laid inside the cover of a book when placed in the standing-press.

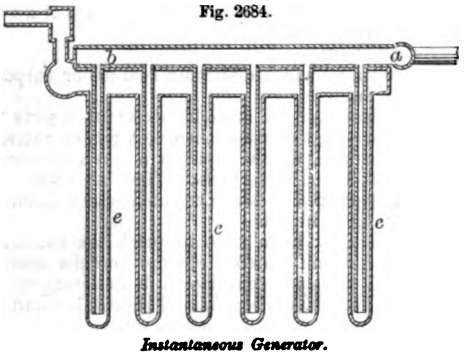
In'side-tool. (*Wood-turning.*) For hollowing out work and bottoming holes.

In'soles. A thickness of cork, felt, flannel, leather, paper, etc., placed inside a shoe to protect the sole of the foot, or to improve the fit of the shoe.

"Suppose one 's short,—
They put cork soles within the heels of her shoes."
ALEXIS; quoted by ATHENÆUS, A. D. 220.

In-stan-ta'ne-ous Gen'er-at-or. A form of steam-boiler or generator, in which a small body of water is injected at a time into a highly heated vessel, flashing into steam immediately. It differs from

Fig. 2684.



Instantaneous Generator.

ordinary boilers in there being no unvaporized water in the boiler. In most cases there is no steam-chest, and the theory has been to inject at each time a quantity sufficient for one impulse of the piston. The term *flashers* has been applied to this form of generators, from the fact that the jet of water instantly *flashes* into steam. Trouble has been found in the rapid corrosion, and in the cracking of the material of the boiler.

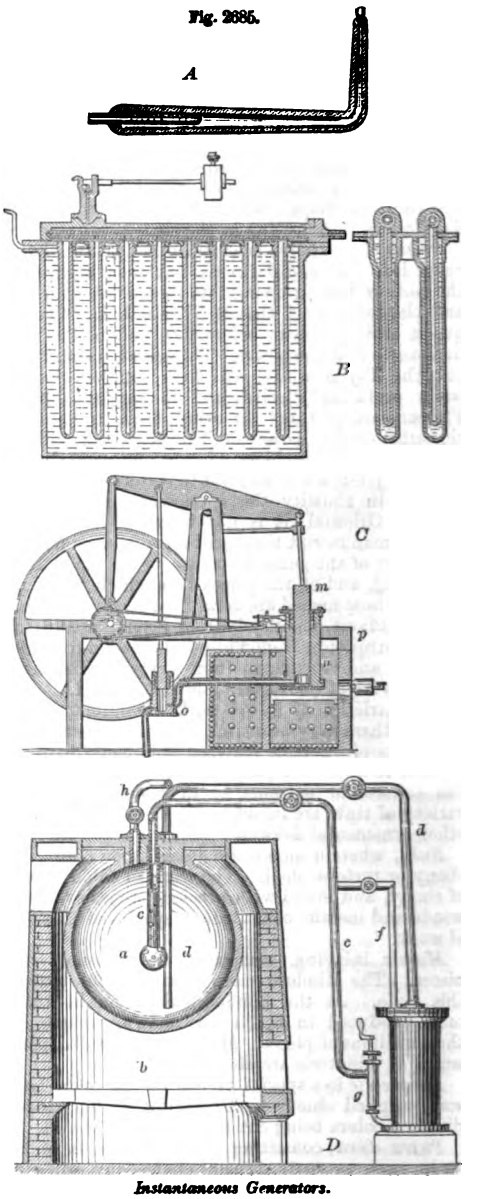
McCurdy's English patent (*A*, Fig. 2685), 1824, has a tube into which is introduced a smaller tube with perforations which deliver a fine shower into the outer tube, which is exposed to the heat of the furnace.

Dr. Alban, of Mecklenburg, patented, in 1825, a device (*B*, Fig. 2685) in which steam was generated in a series of strong vertical tubes, which are submerged for the greater portion of their length in a bath of molten lead. The row of vertical pipes was supplied by water trickling from a pipe above, somewhat as in Fig. 2684, in which, however, the water is conducted from the pipe *a b* by an inner tube down to the bottom of the pipe *e*, in which it is flashed into steam.

Jennings's steam-engine, 1828 (*C*, Fig. 2685), has a piston or plunger *m* which moves in a cylinder *n* when water is injected beneath it by means of the pump *o*. Means of escape for the expanded steam are afforded by a valve working on the frame *p* when the piston has completed its upward stroke.

In Danford's steam-generator (*D*, Fig. 2685) *a* is a spherical vessel, into which water is injected in a spray through pipe *c c* by the force pump *g*. *d* is a pipe through which superfluous water is blown off

Fig. 2685.



Instantaneous Generators.

back to the reservoir. *f* is a branch pipe leading back from the injection-pipe *c* to the reservoir, and by means of a cock such part of the water as may be desired is returned. It forms a means of graduating the amount injected. *b* is the furnace, and *h* the steam-pipe to the engine.

Fig. 2686 is a form in which a metallic cup extends upward from the lower and inner surface of the

Digitized by Google

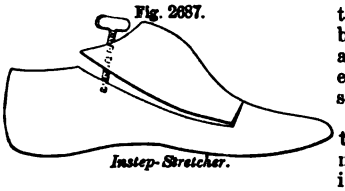
Case's Steam-Generator.

boiler to receive the water or steam thrown in by the feed-pump, and prevent sudden cooling of any part of the boiler.

In'step-stretch'er. A shoemaker's implement for distending the instep of a boot. The movable piece is elevated by a screw.

Fig. 2687.



Instep-Stretcher.

In-suf-fla'tor. An instrument for blowing burned alum or other powder into the larynx or other deep-seated part. See *i*, Fig. 2768.

In'su-lat-ed Col'umn. (*Architecture.*) One unconnected with any wall or building.

In'su-lat-ed Wire. 1. One suspended by insulators (which see) so as to prevent the electric current from going to *earth*.

2. One wrapped with silk or clothed with gutta-percha or caoutchouc to prevent the escape of the electric current.

Among the best insulators are dry air, shellac, sulphur, resins, gutta-percha, caoutchouc, silk, dry fur, glass. See INSULATOR; SUBMARINE CABLE; TELEGRAPH.

Among the materials prominently put forward for the insulation of wire, and forming by themselves or in various combinations the subjects of patents, are:

Animal substances.	Collodion.	Pyroxyline.
Asbestus.	Fiber.	Spun glass.
Ballata.	Gums.	Varnish.
Bituminous substances.	Kerite.	Vitreous coating.
	Paraffine.	Wax.

In'su-lat-ing-stool. A stool with glass legs to insulate a person or an object placed thereon.

In'su-lat-or. (*Electricity.*) A (so-called) non-conducting material; that is, one of relatively very small conductivity, placed between an electrified body and other objects. A device for supporting a wire or other conductor without affording a way of escape to earth of the electricity. It is sometimes of glass or porcelain, with the wire wrapped around it, or tied by wire to it.

The accompanying cut shows several kinds. *a* has a two-hooked head, around which the wire is lapped or wound. The shank is firmly socketed in a glass or vulcanite socket, which screws into the telegraph-post.

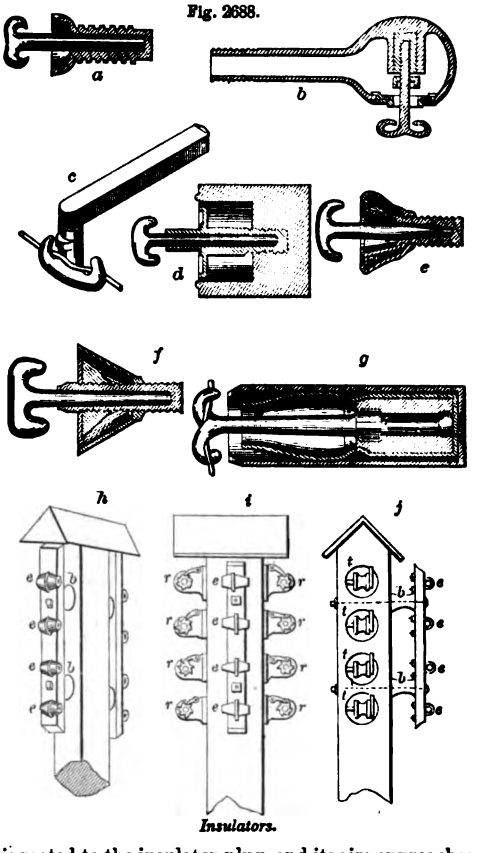
In *b* the inverted cup has a shank by which it is secured to the post, and a socket to hold the end of the pin; between the latter and the edge of the cup is an annular non-conducting disk.

c has a shank to enter the telegraph-post, and a two-pronged stem covered with vitreous enamel.

d has a flanged disk to prevent the accumulation of a film of moisture around the stem.

e, the metallic hook is socketed in a hard rubber-plug which enters the telegraph-post. A flaring cap

Fig. 2688.



Insulators.

is rooted to the insulator-plug, and its rim approaches the hook.

f has a bell around the disk on the rubber socket of the hook-shank.

g is Varley's insulator, which obtained the prize at the Paris Exposition. It has a paraffine cup and a conducting shield which conducts off atmospheric electricity.

h i j are three views of Cooke's insulator (English). *e e* are earthenware thimbles for the wires. *b b* are insulating earthenware struts. *r r* are winding ratchets for the reels *t t* on which the wires are strained. Posts at intervals of 400 yards.

All bodies are conductors of electricity; but while in some the degree of conductivity is so great that they are used to convey the electric fluid, others resist the passage of the current to such an extent that they are said to insulate, or confine the fluid to a more favorable medium. The following bodies ad-

Digitized by Google

mit the passage of electricity about in the order written : —

Silver.	Acids.	Oils.	Paper.
Copper.	Saline solutions.	Ashes.	Feathers
Gold.	Metallic ores.	Phosphorus.	Hair or wool.
Mercury.	Animal fluids.	Lime or chalk.	Silk.
Cadmium.	Water.	Caoutchouc.	Glass.
Zinc.	Vegetables.	Camphor.	Wax.
Tin.	Animals.	Porcelain.	Sulphur.
Iron.	Flame.	Dry wood.	Resin.
Lead.	Smoke.	Gases and air.	Amber.
Platinum.	Vapor.	Leather.	Paraffine.
Carbon.	Earths.	Lycopodium.	Shellac.
Graphite.	Metallic oxides.	Parchment.	Gutta-percha.

In-tagl'io. Cut in; as of the lines in an engraved plate, the sunken letter in the matrix of a type, the design in a seal, punch, or die, which delivers a raised or *cameo* impression. The opposite of *cameo*.

In-tagl'io-type. A process allied to the graphotype and depending upon the production of a friable surface of oxide of zinc on a metallic plate under hydraulic pressure. Upon this lines are drawn with an oleaginous ink, the object of which is to repel a watery solution subsequently applied. A solution of chloride of zinc or analogous salt is washed over it and hardens the surface not protected by the oil. After drying, the surface is brushed over, and the bristles or velvet remove the oxide and ink, leaving an intaglio impression, from which castings may be made in the electro-bath or by stereotyping.

In-ten'si-fy. (*Photography.*) A term applied to various modes of giving strength or increased opacity to the deposit forming the photographic picture on an exposed and developed negative plate. It is frequently effected by continuing the development, using fresh quantities of "developer" and nitrate of silver; also by converting the deposit of metallic silver already formed into new compounds having greater opacity. Sulphuret of silver and mercury and other substances are used.

In-ten'si-ty. 1. A term applied to indicate the energy of the magnetic force, which varies at different places and different times. It is one of the three elements of the magnetic force which are registered by the magnetometrical instruments of the chain of observatories in Europe, Asia, Africa, and America. The other two elements are the *declination* and *inclination*. See MAGNETOMETER.

2. (*Electricity.*) A term which expresses the electro-motive force of a current. An *intensity battery* is one in which the elements are coupled up together, to give a current known as *high-tension*, that is, of great electro-motive force. The term, as applied to a battery, is used in contradistinction to *quantity*.

In-ter-co-lum-ni-a'tion. (*Architecture.*) The distances between the columns composing an architectural front. These are regulated by the diameter of the column, being in —

Aræostyle, from 4 to 5 diameters; diastyle, from 3 to 4 diam.; eustyle, 2¼ diam.; systyle, 2 diam.; pycnostyle, 1½ diameters.

In-ter-den'tal. (*Machinery.*) 1. The space between teeth or cogs.

2. (*Architecture.*) The space between two *dentils*.

In-ter-fer'ing, At-tach'ment for. A device

Fig. 2689.

Interfering-Strap.

fastened to the leg or foot of a horse, to prevent cutting by collision of the feet or shoes. In the example, the rubber guards are attached to the padded strap, which is buckled round the horse's leg. See LEG AND FOOT GUARD.

In-te'ri-or Screw. One cut on an interior or hollow surface, as of a nut, burr, or tap-hole. A *hollow* or *socket* screw.

In-te'ri-or Slope. (*Fortification.*) The slope of the embankment from the crest inward toward the body of the place. See ABATTIS.

In-ter-leave'. (*Bookbinding.*) A book bound with alternating blank leaves, for notes, additions, translations of the text, etc.

In-ter-lig'ni-um. (*Architecture.*) The space between the ends of the tie-beams.

In-ter-me'di-ate Frame. (*Spinning.*) The second fly-frame; an intermediate, in order of time, between the *slubbing* and the *roving* frame.

In-ter-me'di-ate Shaft. The shaft crossing the frame of a marine-engine, to connect the two engines and two paddle-wheels.

In-ter-mit'tent Gear. 1. A wheel having a part of its cogs cut away. A *mutilated* gear.

2. A wheel moved at intervals by a cog, cam, ratchet, rack, or lever; as in counting-machines, meters, registers, escapements, etc.

In-ter-mit'tent Light. One of the characters of light exhibited from lighthouses under the catoptric system. The variations or different characteristics of lights enable a mariner coming within sight of them on a coast to determine his geographical position and bearings.

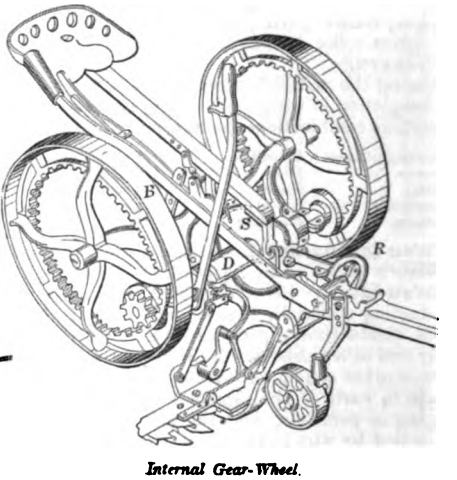
The *intermittent light* bursts suddenly into view, remains steady a short time, and is then eclipsed for half a minute. The effect is produced by the motion of shades in front of the reflectors, alternately displaying and hiding the light.

The other varieties of lights are : —

Fixed, revolving, flashing, colored, double, and these are variously combined. See LIGHT.

The *intermittent* and the *flashing* lights differ in respect of their modes of rising and fading, as also in their duration. The *flashing*-light gives a flash of light every five seconds, with intervals of dimness, the effect being produced by the revolution of a reflector frame with eight sides. The natural world affords several examples of light-carriers. The little fire-fly of the United States, whose common name is rather more than half sublime, *lightning*-bug, is an example of the *flashing*. The fire-flies of Italy and of South America, some species of nocturnal moths, and

Fig. 2690.



Internal Gear-Wheel.

Digitized by Google

the female glow-worm, have luminous patches on the head, sides of the thorax, or the abdomen. The light is considered phosphorescent, but is urged into activity by a nervous action, probably derived from voltaic impulse (as we call it) from the battery, the brain.

In-ter-mit'tent Wheel. This includes all the *escape-wheels;* counting wheels in meters, arithmometers, and registers; stop-motions in clocks and watches; ratchet movements, etc., etc. *See the above.* See also WHEEL; GEARING.

In-ter-mo-dill'ion. (*Architecture.*) The space between two modillions.

In-ter'nal Gear. A wheel whose cogs are on the internal perimeter, as in the example where the pinions on the shaft *D* are driven by engagement with the internal gear of the driving-wheels *B*. Inside the box *S* is a bevel pinion on shaft *D*, which turns a shaft on which is a wrist-wheel *R*, from which proceeds the pitman, which reciprocates the cutter-bar of the harvester.

Many agricultural implements have internal gear-wheels.

In-ter'nal Safe'ty-valve. (*Steam-engine.*) A valve opening inwardly into the boiler to allow air to enter when a vacuum is formed inside by the condensation of steam.

In'ter-nal Wheel. An annular wheel whose cogs are presented internally. See INTERNAL GEAR.

In-ter-ro-ga'tion, Note of. (*Printing.*) A sign (?) indicating a query.

In'ter-tie. (*Carpentry.*) *a.* A horizontal timber framed between two posts.

b. A binding joist.

In'ter-val. A space or distance, as a space between cogs, an *interdental* space.

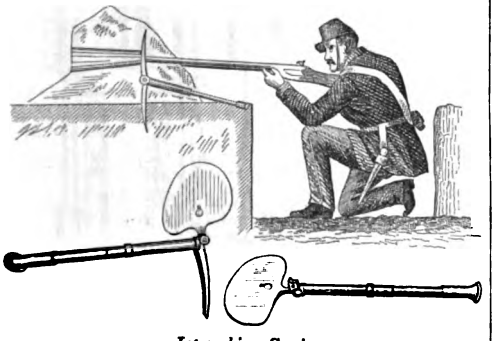
Between the frames in a military mine. A *bay.*

In-tra'dos. (*Architecture.*) The lower surface or *soffit* of an arch.

In-trench'ing Tools. Implements carried by the pioneers of regiments.

A combined spade and pick, invented by Captain Harrison of the London Military Engineers is shown

Fig. 2691.



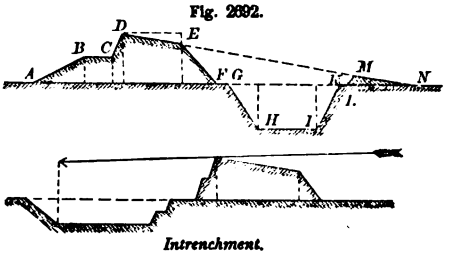
Intrenching-Spade.

in Fig. 2691. The spade and pick are hinged at their junction, to fit the tool for the respective uses. The embrasure is made by a roll of sheet-metal or bark, or a bundle of sticks tied up into a cylindrical shape. The spade has a hole for the barrel and sight.

In-trench'ment. (*Fortification.*) A defensive work consisting of a ditch, and a parapet made from the excavated earth.

The upper figure shows a profile of an intrenchment, in soils of which the natural slope is one perpendicular to one base.

Fig. 2692.



Intrenchment.

A B C D E F is the profile of the parapet.
G H I K the profile of the ditch.
L M N the profile of the glacis.
A B is the banquette slope.
B C tread of the banquette.
C D the interior slope.
D E the superior slope.
E F the exterior slope.
F G the berme.
G H the scarp.
H I the bottom of the ditch.
I K the counterscarp.
A the foot of the banquette slope.
B the crest of the banquette.
C the foot of the interior slope.
D the interior crest.
E the exterior crest.
F the foot of the exterior slope.
G the crest of the scarp.
H the foot of the scarp.
I the foot of the counterscarp.
K the crest of the counterscarp.
M the crest of the glacis.
N the foot of the glacis.

The lower figure shows a cover for troops, having an inner trench of sufficient depth, when aided by the hight of the parapet, to give shelter to troops when standing in the trench. The natural ground serves as the banquette.

In-vag'i-na-to'ri-um. (*Surgical.*) A douche for the vagina.

In'va-lid-bed. One having conveniences for the sick or the wounded, having elevating head and shoulder portion, to give the patient a change of position; a portion which conforms to the shape of the bended knees; conveniences for lifting the patient, introduction of a bed-pan beneath a removable section of the mattress, etc., etc.

In'va-lid-chair. A chair capable of assuming and retaining any required position from the erect to the prone. The figures illustrate the positions, the sustaining devices of the back, seat, leg-piece, and foot-stool being racks and screws. The one illustrated has a capacity for thirty changes.

The invalid-chair which has traveling arrangements is known as a *perambulator* or *locomotive-chair.*

In-vers'or. An instrument invented by Dr. Bird to reverse quickly a voltaic current.

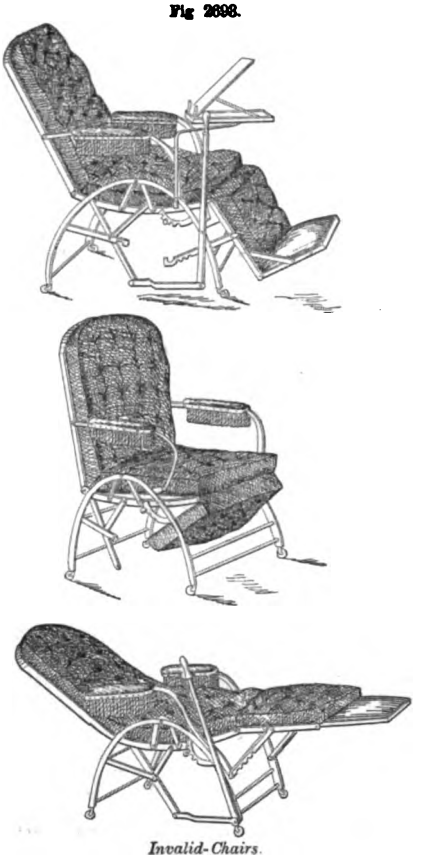
In-vert'. 1. An inverted arch.

2. The floor of a canal lock-chamber. It is usually an inverted arch (convexity downward). See CANAL-LOCK.

In-vert'ed Arch. An arch whose crown is

Digitized by Google

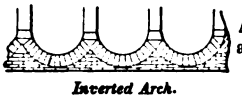
Fig 2693.



Invalid-Chairs.

downward. The *key-stone* being the lowest of the *voussoirs*, and the *springings* the highest. It is used in foundations, the floors of tunnels, etc.

Fig. 2694.



Inverted Arch.

In-vert'ed Com'mas. A sign of the beginning of a quotation (" ").

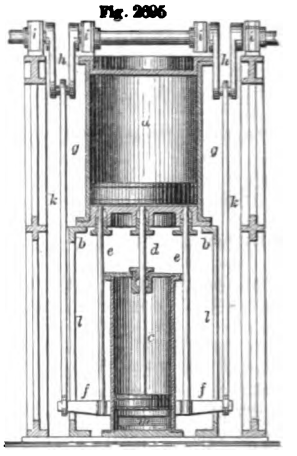
"Age cannot wither her, nor custom stale
Her infinite variety."

In-vert'ed-cyl'in-der Steam-en'gine. Galloway's inverted-cylinder steam-engine is a form of direct-action engine, intended to obviate the use of the beam in marine engines.

a is the cylinder supported upon the frame or platform *b b*; *c* is the air-pump placed beneath the cylinder and concentric with it. The piston-rod *d* of the air-pump passes through a stuffing-box in the cover of the latter, and through another stuffing-box in the cover of the cylinder, and is attached to the steam-piston. Two piston-rods *e e* pass down through stuffing-boxes in the cylinder cover and are keyed to the cross-head *f*, which is curved so as to encompass one half of the air-pump. *g g* are two connecting-rods proceeding from the bearings of the arms of the cross-head to the crank *h h*. *i i* are the plummer blocks which carry the paddle-shaft; two of these are supported by the top of the cylinder, and the other two by the side frames *k k*. *m* is the neck in which is placed the foot-valve connecting the pump with the condensers. *l l* are the guides in which the cross-head *f* works.

In-vert'ed Dou'ble-cyl'in-der Steam-en'gine. A form of steam-engine having two parallel cylinders, each of half the area necessary for the intended power, and combined to form one engine. The cylinders are inverted, being above the crank to which their piston-rods are directed. The four cylinders composing the pair of engines are ranged in a line across the vessel.

Fig. 2695.

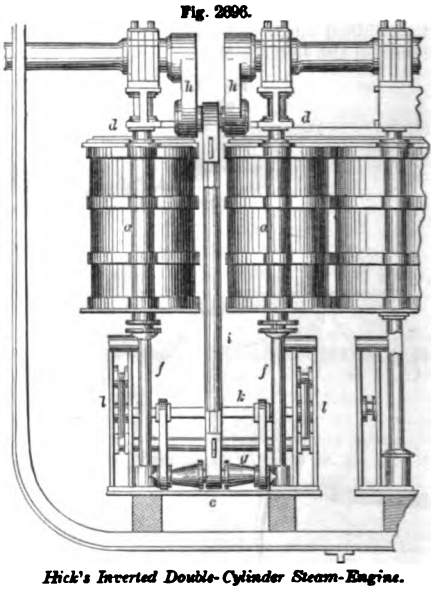


Galloway's Inverted-Cylinder Steam-Engine.

a a are the cylinders which stand upon strong iron columns (not shown) which rest on the foundation plate *c*, and, passing through suitable bosses on the sides of the cylinders, support the entablature plate *d* and the crank pedestals above. The cylinders are placed at a sufficient hight from the bottom of the vessel to allow the piston-rods to work downward. The two piston-rods *f f* are connected together by a cross-head *g*; the stuffing-boxes have self-acting oil-cups.

The power is transmitted directly from the main cross-head *g* below, to the cranks *h h* above the cylinders, by the connecting-rod *i*. The two piston-

Fig. 2696.



Hick's Inverted Double-Cylinder Steam-Engine.

rods *f f* and the cross-head *g* are made to work uniformly together by a strong vibrating cast-iron frame *k*, which forms part of the parallel motion, and with the side levers *l* serves also to work the air, feed, bilge, and brine pumps.

Digitized by Google

Each cylinder has its separate slide-valve in order that it may be nearer to the cylinder than it would be were one used for both. The condenser is not shown, but is beneath the slide-valve case, and the air-pump, foot-valve, and discharge-valve are similar in construction to those used in ordinary engines. The air-pump and condenser are connected by a passage beneath the foundation plate. The waste water is discharged from the hot-well by an overflow pipe through the side of the vessel.

The feature of the double cylinder is copied from *Maudslay's double-cylinder steam-engine*, but in the *Hick's engine* the cylinders are inverted, and the details of the connections are very different. This, like Maudslay's, is a *direct-action engine*, intended to obviate the use of a beam in *marine engines*.

In'ward-dis-charge' Wa'ter-wheel. A form of reaction water-wheel or turbine in which the water reaches the wheel from an outer encircling scroll and passes inward, discharging at the hollow center of the wheel.

I-rail. A double-headed rail with flanges on each side above and below; on the *foot* and *tread*. See IRON, ANGLE.

I'ri-an-kis'tri-um. A hook-shaped instrument used in the operation for artificial pupil by separation.

Ir-i-dec'tome. (*Surgical.*) A knife for operations on the eye.

A journal of February 1, 1801, gives an account of an operation performed by Citizen Demours of Paris upon a left eye, five sixths of whose cornea was perfectly opaque. "The only portion of the latter which remained pervious to light was on the upper part, and so high as to prevent any rays from passing thence through the pupil to the retina. To remedy this, the operation was conceived of cutting an opening through the pupil opposite to the luminous part of the cornea, which was accordingly performed by making a small orifice near the latter, large enough to introduce a very fine pair of scissors, with which a small slit was made in the iris. This opening being above the crystalline lens, and out of the sphere of its action, the patient is obliged to use very convex glasses in order to read, as those persons do from whom the crystalline humour has been extracted in the usual manner."

The Rev. W. H. Milburn gives the following account of the treatment of his eye by the famous oculist Professor Von Graefe of Berlin. The ophthalmoscope had been invented by Helmholtz five years, when, in 1856, Von Graefe, as Mr. Milburn says, "banished to the night of the past the blindness fatally attached to the glaucomatous eye." He relates that the Professor advised him to do without the chloroform, saying: —

"'There is only a slight transparent spot in the cornea into which I can cut; the merest muscular twitch, the deviation of the knife by the tenth part of a hair's-breadth, will ruin the operation; chloroform cannot hold you as steady as your will. What say you? I have confidence in your self-control.'

"I answered, 'Go on without the chloroform.'

"The eyelids were fastened back by springs, and the cutting proceeded.

"First, a linear incision was made through the cornea or colorless part of the eye, and a cut in the iris or colored part behind. Delicate forceps were then introduced to draw the iris out so as to line the new-made opening, and the edges of the iris, clipped with scissors, were skillfully fastened to the surface of the eye. Thus the operation for artificial pupil, called iridectomy, required in this case about four minutes and a half, — longer than usual, — and it can be well imagined that the time seemed much longer to me."

I-rid'i-o-scope. An optical instrument which shows the inside of the eye. Used to detect foreign substances and diseases.

I-rid'i-um. Equivalent, 99; symbol, *Ir.*; specific gravity, 22; nearly infusible.

It is a white, hard, brittle metal, more difficult to fuse than platinum, and the heaviest of all known substances.

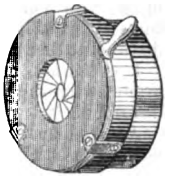
It has been used for forming the tips of gold pens.

The alloy of iridium and osmium, called iridosmine, is the hardest of all alloys. It forms the point of the "everlasting pen," made by Hawkins of England, and is ground by diamond-dust.

Ir-i-dos'mine. An alloy of iridium and osmium. The hardest of all known alloys.

I'ris-cope. An instrument contrived by Dr. Reade for exhibiting the prismatic colors. Sir David Brewster describes it in the "Phil. Trans." for 1841 as a plate of polished black glass, having its surface smeared with a solution of soap and dried by wash-leather. On breathing through a tube upon the glass, the vapor is deposited in brilliant colored rings.

Fig. 2697.



Iris-Diaphragm.

I'ris-di'a-phragm. (*Optics.*) A contractile diaphragm, simulating the action of the natural iris, to regulate the size of the aperture in a microscope through which light passes.

I'ron. 1. The most useful and abundant of the metals.

Equivalent, 28; symbol, *Fe.*; specific gravity, cast-iron, 7.2, wrought-iron, 7; fusing-point, 2,786° Fah. The ores principally worked are the oxides and carbonates, the metal in combination with oxygen, or with oxygen and carbonic acid.

The protoxide is an antidote for arsenic.

The peroxide is an ore, and is used as a pigment (ocher).

The loadstone is a magnetic oxide.

The bi-sulphuret (pyrites) is the bane of the gold and silver miner. Pyrites is now roasted for the production of sulphuric acid.

The protosulphate (green copperas) is used in dyes and inks; and calcined forms *crocus*, *rouge*, *cocothar*, for polishing.

The useful forms of iron are cast-iron, steel, and wrought-iron. The former two are compounds of iron and carbon, being carburets or carbides of iron. Cast-iron has the larger proportion of carbon in its composition. Wrought-iron is nearly pure iron, but it has generally some traces of carbon, sulphur, and phosphorus. The less the better, but the two last are hard to eliminate.

Iron was found, so says the chronicle, on Mount Ida, by the Dactyles, after the burning of the forest by lightning, at a period answering to our 1432 B. C. The Greeks claim the first discovery of it, of course. How many centuries it had been used in China, India, and Egypt can hardly be determined. Moses, who died 20 years before the era assigned, credits one with the invention who had been dead 2,000 years when he, the great lawgiver, wrote.

Chariots, axes, bedsteads, harrows, weapons of iron, are mentioned in Hebrew history between 1490 B. C. and 1040 B. C. Jeremiah and Ezekiel speak of iron, and mention two qualities, one of which the latter calls "bright iron," probably steel. The same distinction is made by Hesiod (850 B. C.).

Some doubts have been expressed as to the render-

Digitized by Google

ing of the Hebrew passage which speaks of Tubal Cain as an artificer in *iron*, and the passage which speaks of the *iron* bedstead of Og, King of Bashan, about 1450 B. C. The Arundelian marbles place the use of iron in 1370 B. C., and other authorities go back to 1537 B. C. These corroborate the iron bedstead of Og. Extremes meet, and we have lately revived the use of the material first recorded as used for that purpose. Moses mentions an iron furnace 1490 B. C., and Job speaks of iron as "taken out of the earth."

Gold, silver, and copper, and alloys of the last, were, no doubt, used before iron, and it would be reasonable to expect that such would be the case, as they are so readily obtained by simple metallurgic operations, while iron is more refractory.

The existence and uses of iron among the ancient Egyptians are pretty well proved by the paintings, in which the iron or steel knives and sickles are distinguished from the bronze by the color; one being blue, the other a reddish-brown.

In Dr. Abbott's collection, now in the possession of the New York Historical Society, are the following articles of iron, stated by the doctor to be of undoubted authenticity. They were found at Thebes:—

Iron helmet, neck-guard, and breast-plate of scale armor, with the name of Shishak, who invaded Judea 971 B. C.

An iron spatula, iron arrow-head, warrior's flail with iron studs, and some emblematic articles of iron.

The ancient iron mines of the Egyptians have been lately discovered by English explorers. The process was wasteful, and the slag contains 53 per cent of iron. The sites are in the vicinity of Mt. Sinai, and it is proposed to work over the *débris* of the former workings.

Of the first use of iron in Egypt, Wilkinson says, we have no certain record. His surprise at the execution of the sculptures is very natural, but he does not appear to have estimated the character of the alloys of copper and tin, some of which are very hard. (See ALLOY; BRONZE.) Belzoni discovered an iron sickle-blade beneath a granite sphinx at Karnak. Colonel Vyce found an iron blade imbedded in the great pyramid. Layard found a steel cross-cut saw, and other articles of iron, at Nimroud; the saw is now in the British Museum. The butchers of Thebes and Memphis had steels slung from their belts. At Babylon the stones of the bridge across the Euphrates, built by Nitocris, were cramped by bands of iron set in lead. Thucydides says the blocks of the walls of the Pireus were fastened in the same way. Theseus, who ascended the throne of Athens 1235 B. C., was buried with a bronze sword and spear. Some have dated the use of iron in Greece at 1406 B. C., but Hesiod makes it later. Homer generally speaks of bronze arms, but mentions iron.

We learn from the "Iliad" that at the time of the siege of Troy (1184 B. C.) iron was used in making axes, shipwrights' tools, axles for chariots, plow-points, sheep-hooks, and some other agricultural implements. "As the smith plunges the loud-hissing axe into cold water to temper it, for hence is the strength of iron," etc., shows clearly that the writer or compiler of the "Odyssey," whom we are content to call Homer, lived in a time when iron and steel were forged and tempered.

About 500 B. C., and thereafter, steel was imported into Greece from the Chalybes, a people inhabiting the shore on the southeast of the Black Sea, and the use of bronze for weapons terminated soon after. Marathon was fought 460 B. C. The steel was called Chalybian, and we retain the name in connection with waters, as Chalybeate springs.

In Asia the Chalybes were noted for their works in iron, from which they obtained great profits. — XENOPHON, *Anab.*

Aristotle mentions that their arenaceous ores were washed, and he also partially describes the operation of making wootz in India; Diodorus Siculus says that in the island of Ethalia the ores were roasted and broken fine before melting. It was *wrought*-iron that was produced and employed, and not *cast*-iron, which is a comparatively recent production, and it is probable it was all obtained, by a primitive direct process, from rich and easily reducible ores.

The early means for the reduction of iron from the ore were small furnaces with cold blast, in which rich ore was heated in contact with incandescent charcoal, the viscid mass being hammered to remove earthy impurities. This plan is yet practiced in India, Africa, Malaya, Madagascar, and forms the

"Mass of iron, shapeless from the forge,"

offered by Achilles as a prize at the funeral games of Patroclus, recorded in Homer's twenty-third book of the "Iliad."

Dr. Livingston refers to the iron-smelting furnaces of the tribes encountered in his "Expedition to the Zambesi." The articles produced by these peoples are hammers, tongs, hoes, adzes, fish-hooks, needles, and spear-heads.

King Porus presented to Alexander the Great a wrought bar of laminated steel, for which Damascus was subsequently so famous that it is known as Damascene. One of the most remarkable forgings in the world, if it be one, is the wrought-iron pillar within the precincts of a mosque near Delhi. It is a shaft with a capital 22 feet high above ground, and a greater length below. Its probable weight is over 38,000 pounds. It has an inscription in Sanscrit, which records that it was erected by King Dhava of the Hindoo faith.

The character of the Sanscrit inscription, according to the English linguists of Hindostan, indicates a period at about A. D. 400. See FORGING.

The examples cited from the writings of Moses, Hesiod, and Homer, the attestation of the recovered implements from Egypt and Nineveh, and the Egyptian paintings, render it useless to cite the facts within the notice of the gossiping and credulous Pliny, who professes to give the early history of the metal. Palestine, Asia Minor, Scythia, Elba, and Spain were each celebrated in their time for the production of iron. From Iberia the art spread to Gaul, and from the latter, probably, to Germany.

An army of Gauls was defeated by the Romans, 222 B. C., chiefly because the swords of the former bent after a blow or two, and required straightening by the foot, while the superior metal of the Romans stood the brunt.

Strabo mentions that one of the exports of Britain was iron; the bold islanders met their invaders with scythes, hooks, broadswords, and spears of iron.

The arrival of the Romans and the introduction of artificial blast, which the Romans had derived from their Eastern neighbors, gave a great impulse to the iron works of England.

Under Adrian, A. D. 120, a fabrica or military forge was established at Bath, in the vicinity of iron and wood.

During the Roman occupation of England, some of the richest beds of iron ore were worked, and the *débris* and cinders yet exist in immense beds to testify to two facts: one, that the amount of material worked was very great; the other, that the plans

Digitized by Google

adopted were wasteful, as it has since been found profitable to work the cinder over again.

During the Saxon occupation the furnaces were still in blast, especially in Gloucestershire.

The early Norman sovereigns were so intent upon skinning the Jews and the Saxons, that it became dangerous to succeed in any business, success being an invitation to the barons to plunder. Accordingly, we find in the time of King John that iron and steel were imported from Germany.

The business lumbered along for some centuries, the government tinkering at it now and again, the exportation being prohibited in the fourteenth century, and the importation of iron in the fifteenth century.

The direct method of obtaining wrought-iron from the ore prevailed until the commencement of the fifteenth century, but then gradually gave way to a less direct process, but one more convenient when handling large quantities. Blast-furnaces, operating by the aid of strong blast, to *melt* the iron and obtain *cast-iron*, which is carbureted in the process, were in use in the neighborhood of the Rhine about A. D. 1500. A second process in a *forge-hearth* was used to eliminate the carbon and other impurities, and the result is *wrought-iron*. The *puddling-furnace* was invented more than 250 years afterward.

In the sixteenth century (1590), we find a notice of a mill for slitting iron into bars for smiths' use by Godfrey Bochs.

The change from the use of wood coal to that of mineral coal was only accomplished in England after a great many futile attempts.

In the reign of Elizabeth, blast-furnaces were of sufficient size to produce from two to three tons of pig-iron per day by the use of charcoal. In the small works, the iron was made malleable before being withdrawn from the blast-furnace, and in larger works was treated by the refinery-furnace.

Wood becoming scarce, and a number of furnaces having gone out of blast, in 1612, Simon Sturtevant was granted a patent for thirty-one years for the use of pit-coal in smelting iron. Failing in his proposed plans, he rendered up his patent the following year.

The patent was granted in 1613 to John Ravenson, who also failed, and resigned his patent, which was again and again granted to succeeding inventors and adventurers who believed themselves possessed of the means and knowledge for accomplishing the object.

In 1619 the patent came into the hands of Dudley, who at the age of twenty left Oxford University to take charge of his father's furnaces at Pensnet, in Worcestershire, and who succeeded in producing three tons of iron per week in a small blast-furnace by the use of coke from pit-coal. The parties who yet possessed plenty of wood, and with whom the production of iron was fast becoming a monopoly, urged the charcoal-burners to destroy the works of Dudley, which was done. Dudley's patent was granted for thirty-one years, which would bring it to 1650, the time of the Protectorate, when England had a ruler fit to succeed Queen Bess. The celebrated statute of King James, limiting the duration of patents to fourteen years, was passed in 1624.

From the circumstance that Dudley petitioned Oliver Cromwell and Council for a renewal of the term, two things are evident: one, that he had pursued the scheme and anticipated or had achieved success; the other, that the limitation of his patent from thirty-one to fourteen years had not been enforced or had been revoked. Dudley charges that the extension of his term was refused by the influence of favorites of the Protector, who wished to share in his profits, and on his refusal defeated his application for extension.

It is likely that Dudley only received a moderate remuneration for his pains, as no one seems to have taken any interest in the business after it was thrown upon the public by the expiration of his patent. Iron of poor quality continued to be made in districts where wood was scarce, and of good quality from charcoal in places where the forests yet remained. The demand for iron continuing to grow, — a natural effect of advancing civilization, — iron was exported from Sweden and Russia in large quantities and of excellent quality. The forests of these countries gave them a natural advantage over England, whose woods had by this time become thinned out, so that the use of wood for iron smelting had been forbidden by act of Parliament in 1581, within twenty-two miles of the metropolis, or fourteen miles of the Thames, and eventually was forbidden altogether.

The art of making iron with pit-coal, and of casting articles of iron, was revived by Abraham Darby, of Colebrookdale, about 1713, and was perseveringly followed, although it was but little noised abroad. In the Philosophical Transactions for 1747 it is referred to as a curiosity.

Certain parties had attempted to smelt iron in clay pots exposed in a furnace, resembling that used for glass, to the flame of a pit-coal fire, expecting to procure the iron by tapping the pots. The scheme, which might have answered with a more tractable material, failed in the case of the iron ore.

Tinning of iron was introduced from Bohemia in 1681.

The extension of the iron manufacture dates from the introduction of the steam-engine, which increased the power of the blast, and the blowing engines driven by manual, horse, or ox power were superseded by engines. The dimension of the blast apparatus was increased from time to time, and about 1760 coke was commonly used in blast-furnaces. In 1760 Smeaton erected at the Carron works the first large blowing cylinders, and shortly after Boulton and Watt supplied the steam-engines by which the blowers were driven. Peter Onions, in his patent of 1783, described the *rationale* of the puddling process; and Henry Cort, of Gosport, in 1784, made it practicable, and added grooved rolls, by which the puddled bar was drawn. Neilson, of Glasgow, introduced the hot blast in 1828. Aubulot, in France, in 1811, and Budd, in England, in 1845, heated the blast by the escaping hot gases of the blast-furnace. The Calder works, in 1831, demonstrated the needlessness of coking when hot blast is employed.

Experiments in smelting with anthracite coal were tried at Mauch Chunk in 1820, in France in 1827, and in Wales successfully by the aid of Neilson's hot-blast ovens in 1837. The experiment at Mauch Chunk was repeated, with the addition of the hot blast, in 1838, 1839, and succeeded in producing about two tons per day. The Pioneer furnace at Pottsville was blown July, 1839.

The first iron-works in America were established near Jamestown, Virginia, in 1619. In 1622, however, the works were destroyed, and the workmen, with their families, massacred by the Indians. The next attempt was at Lynn, Massachusetts, on the banks of the Saugus, in 1648. The ore used was the bog ore, still plentiful in that locality. At these works Joseph Jenks, a native of Hammersmith, England, in 1652, by order of the Province of Massachusetts Bay, coined silver shillings, sixpences, and threepences, known as the "pine-tree coinage," from the device of a pine-tree on one face.

Of the special processes for treating and purifying, a few may be cited: —

Smelting by blast with charcoal, pit-coal, and coke, and with the addition of limestone or shells as a flux, have been noted. See *supra*; also BLAST-FURNACE.

Puddling and *boiling*, somewhat similar operations for burning the carbon of pig-iron and eliminating other impurities, are considered under those heads. See also DECARBONIZING-FURNACE; REDUCING-FURNACE; MALLEABLE IRON; BESSEMER PROCESS; FORGE, etc. See list under METALLURGY.

Steel processes are considered under STEEL. See also BESSEMER PROCESS; CONVERTOR; CEMENTATION-FURNACE, etc.

A process for decarbonizing molten cast-iron by applying an air-blast in the hearth of a blast-furnace was invented by C. Shunk.

Kelly patented in the United States, in 1857, a mode of decarbonizing molten crude cast-iron by running it into a cupola or vessel, separate from that in which it was melted, and blowing through it from the bottom a blast of air, so as to burn out the excess of carbon, — the blast being strong enough to furnish rapid combustion of the carbon, and thereby retain the temperature and fluidity of the molten metal until sufficiently refined, without the use of other fuel.

Bessemer worked as an original inventor in the same line, and much improved the process in general and in detail. Holley gave it its American form. See BESSEMER PROCESS.

The process of decarbonizing the molten iron by addition of manganese is found in Reynolds's English patent, about 1800.

Mushet's patent consisted in the introduction of manganese or other highly oxidizable metals, during the process of melting the crude iron, for the purpose of detaching and removing oxidized substances.

Krupp uses spiegeleisen.

Schmit, of the Troy Bessemer works, recommends ferro-manganese in small quantities and in solid pieces, as a recarburizer.

Clay's process of making wrought-iron direct from the ore (English, 1843) consists in sifting rich ground ore, mixed with $\frac{1}{10}$ weight of coal, into the chamber of a furnace where it is puddled and balled; after this it is shingled and rolled in the ordinary manner.

Jameson's process consists in exposing the calcined and crushed ores in a series of deoxidizing chambers, where it is exposed to the heat of the burning gases which come from the furnace below. It is pushed from the floor of one chamber to another, and in the last chamber is exposed to hydrogen generated by the decomposition of a jet of steam injected upon it to aid in ridding it of sulphur and phosphorus. Thence to the charcoal bed and refining chamber, where the *loop* is formed, and whence it is taken to the hammer.

Henderson's process for the manufacture of iron-steel (patents, 1870) embraces the use of fluor-spar and titaniferous ores, and treating crude ores by fluorides and oxides.

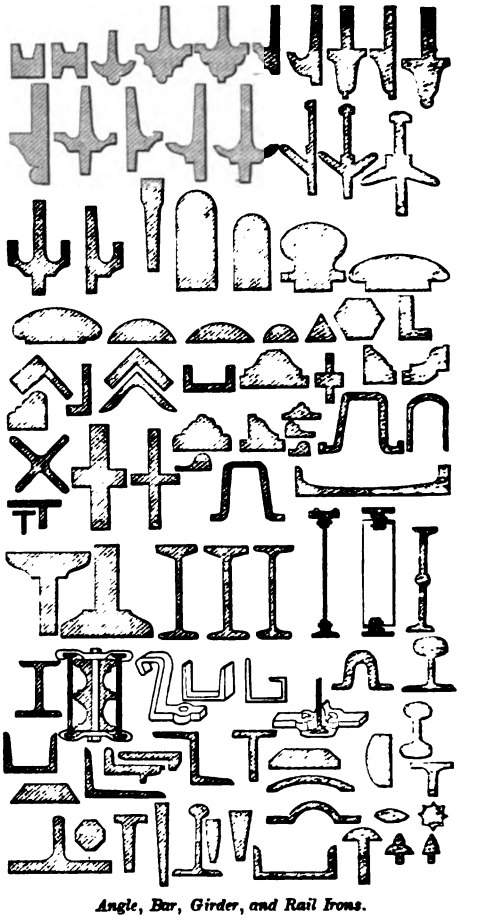
The Ellershausen process consists in the conversion of crude cast-iron into wrought-iron by the admixture of granulated iron ore, a layer of molten iron, and a sprinkling of powdered ore, alternating in molds. These blooms are put in a reverberatory, puddled, squeezed, and rolled.

Bessemer has patented in England a mode of applying to the decarbonization of iron, nitrates, chlorates, and other salts, which evolve oxygen when heated.

By Blair's process, patents Nos. 126, 923, 924, 925, of 1872, the oxides of iron are subjected, in contact with solid carbon for a certain time, to a uniform red heat, the access of other oxygen during the process being prevented. By this means the oxygen leaves the iron and unites with the carbon, passing off in a gaseous state, while the iron remains, being reduced to a metallic state as iron sponge. The metallic iron thus obtained is, however, in a very sensitive condition while hot, and in that state absorbs oxygen with great avidity; but, if cooled before being brought into contact with the atmosphere, it does not readily re-oxidize.

After reduction, the iron sponge retains the shape of the ore from which it is derived, but somewhat expanded in bulk, and with very marked loss of weight. It has a spongy texture; is readily sectile; is easily indented by the finger-nail; chews like lead between the teeth, and polishes quickly to a silvery luster. Its color, unless influenced by some coloring matter accidentally present in the ore, is grayish,

Fig. 2698.



Angle, Bar, Girder, and Rail Irons.

varying from blackish to a clear lead-color. When powdered and burned in the open air it sparkles brilliantly, as does iron burned in an atmosphere of oxygen.

Taylor describes a method of making cast-iron from oxides of iron by reducing magnetic iron ores

Digitized by Google

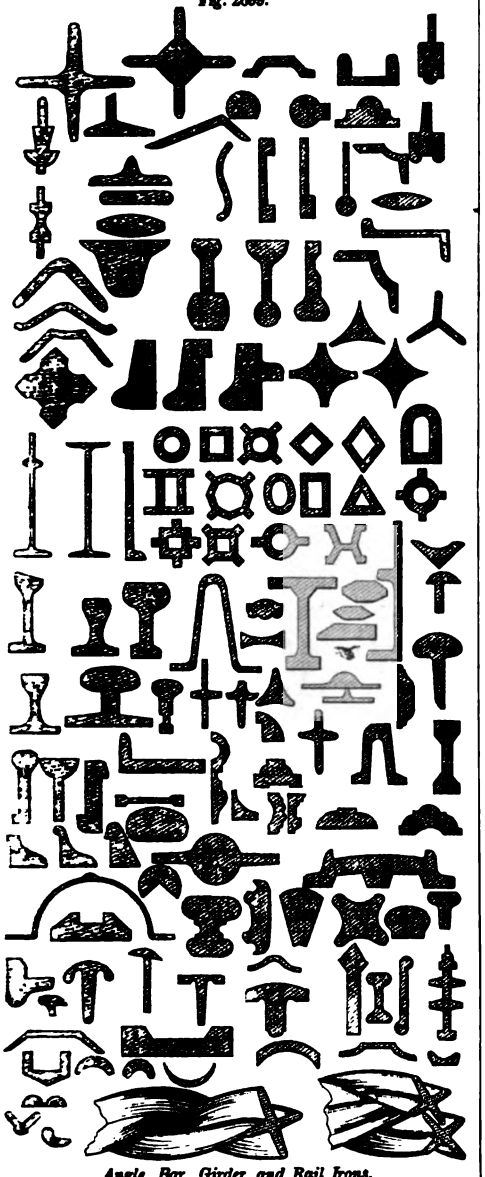
to powder and separating the iron oxides therefrom by magnets, and preparing and uniting the same for use in the furnace.

See STEEL. Also, and much better, see Percy's "Metallurgy, Iron and Steel," London, 1864.

2. An instrument or utensil of iron.

A *box-iron*, *flat-iron*, *smoothing-iron*, *sad-iron*, or

Fig. 2699.



Angle, Bar, Girder, and Rail Irons.

Italian-iron is a form of heated instrument for smoothing damped clothes, starched or otherwise.

The *iron-heater* is a piece of metal or wire heated in the fire and placed in an urn, *box-iron* or *Italian-iron*, to heat it.

The *iron-holder* is a pad upon the handle to protect the hand; or is a ring or tripod to stand the iron upon temporarily.

Tailors' and *hatters'* irons are forms of smoothing-irons adapted to the uses of the said operatives. A tailor's iron is known as a *goose*.

A *plane-iron* is the bit or cutting portion of a joiner's plane.

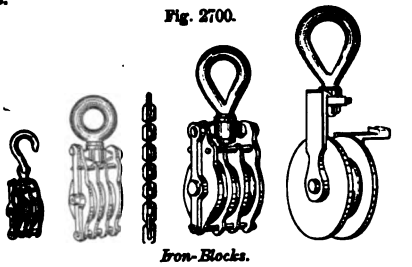
3. The iron portion of a thing, as a *boom*-iron, or *pump*-iron; a *clip* of a single-tree; the *plow*-irons, the iron portions of a plow, etc.

I'ron, An'gle, etc Figs. 2698 and 2699 show forms of rolled iron for bridges, girders, beams, rails, etc.

See Brandt's "Eisen-Konstructionen," Berlin, 1865; Heinzerling's "Die Brücken in Eisen"; Fairbairn's "On the Application of Cast and Wrought Iron," London, 1854; Zorè's "Recueil de Fers Spéciaux," Paris, 1853; and Mäurer's "Die Formen der Walzkunst und das Façoneisen," Stuttgart, 1865. See also ANGLE-IRON.

I'ron-block. A tackle-block with an iron shell and strap. The illustration shows several kinds and sizes.

Fig. 2700.



Iron-Blocks.

I'ron-boat. One made of iron-sheets, riveted together.

I'ron-bot'tle. An iron bottle with a screw-plug, for holding quicksilver. It is made by swaging and drawing from a disk of tough wrought-iron. After being brought by swaging to the form of an open-ended cylinder, it is put on a steel mandrel and driven through holes of decreasing dimensions till it becomes a long cylinder. The neck is pressed and twisted into shape and fitted with a screw-stopper.

I'ron-bridge. Iron-bridges were first used in China. — DU HALDE.

Cast-Iron Bridges.

Digitized by Google

Iron-bridges are of many forms: cast-iron arches, lattice, truss-girders, arched beam, or arch and truss, tubular girder, tubular arch, suspension. These are most of them considered under these separate heads.

The first built in England was an arch of cast-iron sections, erected in 1779 over the Severn, at Coalbrookdale, Shropshire, England, by Abraham Darby and John Wilkinson. It had five ribs, each cast in two pieces, secured where they join at the crown of the arch by a cast-iron key-plate, and connected together horizontally and vertically by cast-iron braces, formed with dovetails and forelocks. The ribs are covered with cast-iron plates, and the railing to the sides was of iron.

Dimensions of some of the principal Cast-Iron Bridges.

§ Whole length, 5,294 feet; weight of iron, 8,723,000 pounds.

The iron truss-girder bridge over the Tay in Scotland, about 1¼ miles west of Dundee, is to be 10,320 feet in length, and to have, commencing on the Fifeshire side, spans as follows: three spans of 60 feet, two of 70, twenty-two of 120, fourteen of 200, sixteen of 120, twenty-five of 66, one of 160, and six of 27 feet. The bridge will thus have eighty-nine spans, and has a hight of about 78 feet above mean high water.

The Girard Avenue Bridge, Philadelphia, is shown on the opposite page. It crosses the Schuylkill River at the entrance to the Fairmount Park, and was built by the Phœnixville Bridge Company. The bridge is 100 feet wide; the frame is entirely of iron, the flooring being iron joists covered with corrugated iron plates and asphate concrete, and granite blocks laid in cement.

I'ron-cham'ber. (*Puddling.*) That portion of the puddling-furnace in which the iron is worked. The *reverberatory-chamber*, *charge-chamber*.

I'ron-clad Ves'sel. One having the exposed portion of the hull protected, in whole or in part, by a covering of iron.

At the siege of Gibraltar in 1782, the French and Spaniards employed floating batteries, made by covering the sides of ships with junk, rawhides, and green timber to the thickness of seven feet, and bomb-proofing the decks. The largest of these vessels was 1,400 tons burden; their armament was 32-pounders, and they were manned by 500 men. They had furnaces for heating shot. These vessels were finally set on fire by red-hot shot. In 1813, Fulton constructed a steam floating-battery for the United States.

The first application of iron for this purpose was by the French, during the Crimean war in 1855, to gunboats. These had a displacement of about 2,000 tons, were 172 feet in length, 43 feet beam, and 17 feet deep, protected by 4½-inch plating, and mounted 16 guns, all of which could be fought on one side. They were frequently struck by shot, but received no severe injury. The English at the same time built gunboats very similar in size and construction. As far back, however, as 1842, Mr. Theodore R. Timby had invented an iron-plated turret, adapted either to ships or fortifications. See MONITOR; TURRET.

The civil war of 1861 gave a great impetus to improvements in iron-clad vessels; the success of the monitors inducing the governments of Europe to engage extensively in the construction of iron-clads, the tendency being constantly to increase the thickness of the armor.

Iron-clad vessels are of the monitor or turret class, carry guns merely in broadside, or have the two systems combined.

The iron-clads employed by the United States on the Western rivers during the late civil war were mainly river steamers, the sides above the water-line placed at an

Wrought-Iron Bridges.

angle of about 30°, and plated with 2 to 4 inches of iron, backed with 3 feet of oak. They carried 4 to 16 guns, and some of them were made to float in 2½ feet of water. They were calculated to fight "bow on," and were practically invulnerable to 100-pound shot when in this position. The "Benton," "Essex," "Carondelet," "Lexington," and a large number of others, were of this construction. Toward the latter part of the war a number of monitors were built for service on the Mississippi.

A class of vessels plated with ¾-inch iron were jocularly called tin-clads. Their armor was a protection against rifle-balls, but was easily penetrated by shells from the lightest field-pieces.

Improvised iron-clads, consisting of river steamers plated with railroad-iron, were used by both parties on the Mississippi. They were simply makeshifts, but in some cases were found to be quite formidable.

The "Galena" was one of the first three sea-going iron-clads built for the United States government, the "Monitor" and "New Ironsides" being the other two. The "Galena" was a two-masted vessel, 1,000 tons, 300 horse-power, and pierced for 18 guns. Her armor was of overlapping corrugated plates, from 2½ to 4½ inches in total thickness, backed by 18 inches of oak and walnut. In service she was found not to resist shot much heavier than 64 pounds at short range, and she lost many men in her first attack on Fort Darling.

The "Monitor," Ericsson's first iron-clad, was a vessel of about 1,000 tons, 172 feet long, 41 feet beam, 9 feet depth of hold, the deck about 2 feet above the water-line, and overhanging the hull some 6 feet on the sides and 20 feet astern. Under this "overhang" the screw worked. The deck, and the sides for 6 feet below the water-line, were plated with five inches of iron, in one-inch plates, breaking joints. The turret amidships was a round box of iron, built up of inch plates to 20 feet in diameter, 9 inches thick, and 9 feet high, with a grating or covering of railway bars. It contained two 11-inch guns. Her defeat of the "Merrimac" in Hampton Roads, March 9, 1863, rendered this little craft historic. She foundered in a storm, off Hatteras, December 31, 1862. See MONITOR. See also ARMOR-PLATING, p. 152.

The "Ironsides," completed at Philadelphia in 1862, was the only formidable side-gun iron-clad ever put in service in the United States. She was 240 feet long, 58½ feet beam, and rated 3,250 tons, 1,600 horse-power. She was plated with solid plates 4½ inches thick, and carried eighteen very heavy guns, sixteen 11-inch guns, and two 200-pounder rifles. She was found to resist all but the very heaviest shot at the closest range, thus proving the superiority of solid over laminated armor. She was struck more than 70 times in one day, and several hundred times in all, while serving in front of Charleston, but was never seriously injured. She was, unfortunately, burned at the wharf in Philadelphia, 1865.

The "Dunderberg" is an inclined armor broadside ship, of 7,000 tons displacement. Her armor consists of 3½ and 4½ forged iron plates, over a timber backing of from one to six feet. She was built in New York by W. H. Webb, Esq. The contract price was $1,400,000. She was sold by permission of Congress to the Emperor of the French for $3,000,000, having cost much more than was anticipated.

The "Roanoke" is an old United States wooden ship-of-the-line, cut down to near the water-line, plated with 4½ inches of iron, and has three turrets, 11 inches thick, each carrying two 15-inch guns. She was only used for harbor defence, being found to roll so much as to be almost unseaworthy.

The "Merrimac" was a United States wooden ship-of-the-line, and was set on fire at the Norfolk Navy Yard when that place was abandoned at the breaking out of the war. The hull was raised by the Confederates, and a false deck put on, above which an iron-clad fort was built, the sides sloping upward at an angle of about 30°. She carried ten heavy guns, some of them rifled 100-pounders. Her first engagement, March 8, 1862, showed her to be more than equal to a fleet of wooden vessels, she having sunk the "Cumberland" and crippled the "Congress" in a few hours. She was defeated next day by the "Monitor," and blown up two months later to escape capture.

The "Atlanta" was an iron vessel cut down, plated with two thicknesses of 2-inch iron plates over heavy wooden backing. She was captured by the monitor "Weehawken," June 17, 1863, having been disabled at the fourth shot from that vessel.

Most British iron-clads are built on the broadside principle, the "Captain," built something on the monitor plan, having foundered in a moderate sea, carrying down all on board.

The "Lord Clyde," said to be the fastest English iron-clad, is 280 feet long, 59 feet beam, 21 feet draft, 4,067 tons burden. The cylinders of her engines are 116 inches diameter, having 4 feet stroke. The boilers, nine in number, have brass tubes 2½ inches in diameter, with an aggregate heating surface of 19,000 square feet.

On her trial trip a speed of 13½ knots per hour was attained.

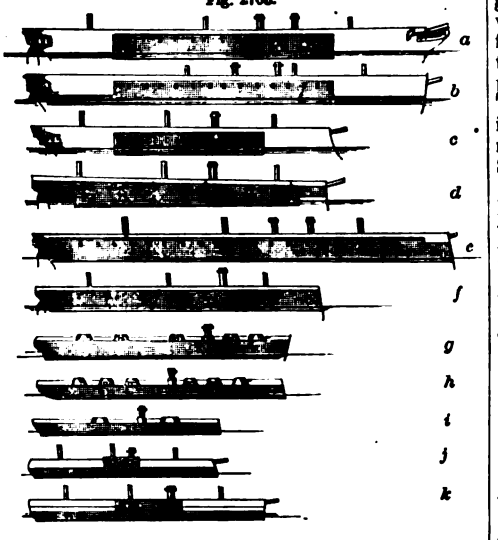
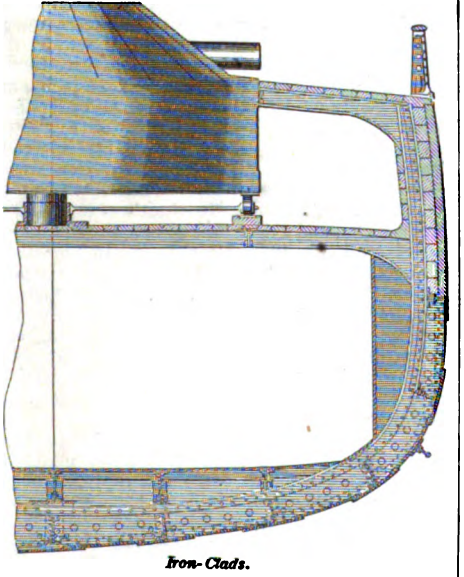
The "Hercules," launched in February, 1868, is 325 feet long, 59 feet beam; tonnage, 5,662; draft, 24½ feet when fully equipped. Her ram is a solid mass of iron, weighing 5 tons. She has 5 water-tight bulkheads. The iron plating is from 6 to 9 inches thick, the former thickness extending the entire length of the vessel to several feet below the water-line. This is backed by 10 inches of teak, 1½ inches

Fig. 2702.





Iron-Clads.

of iron, 20 inches more of teak, and ¾ inch of iron. The engines, of 1,200 nominal horse-power, are capable of being worked up to 7,000 horse-power. The weight of iron used in construction of the vessel is stated at 9,520,000 pounds; of wood, 1,814,400 pounds.

The thickness of armor-plating has been greatly increased since its first introduction; thus the "Warrior," built in 1861, has plating 4½ inches thick, that of the "Bellerophon" is 6 inches, and that of the "Hercules," as already stated, 9 inches. The French have increased the thickness of their plating to 15 centimetres, about 6 inches; and the "Marengo" and "Ocean" have plating 20 centimetres, or nearly 9 inches, in thickness.

Plates for experimental purposes have been rolled 15 inches thick, and it is claimed that plates of sound and uniform quality can be rolled 10 inches thick.

To resist the attacks of iron-clads the British government is erecting at Spithead two forts, plated with 15-inch iron. Each fort is 700 feet in circumference, 230 feet in height, and is armed with two tiers of guns, one consisting of twenty-four 600-pounders, and the other of twenty-five 400-pounders. The two will command the only deep channel leading from the sea to Portsmouth Harbor. The estimated cost of each fort is about £1,000,000 sterling. See ARMOR-PLATING.

Fig. 2703 shows broadside views of a number of English iron-clads, and is introduced to illustrate the modes of arming and of protecting; the shaded portions indicating the partial protection only, afforded in some instances to the battery and engines, and at about the water-line.

a shows the "Warrior" and "Black Prince" class of 6,039 tons.

b, the "Achilles," of the same size.

c, the "Defence" and "Resistance," 3,668 tons.

d, the "Hector" and "Valiant," 4,063 tons.

e, the "Northumberland," "Minotaur," and "Agincourt," 6,621 tons.

f, the "Prince Consort," "Royal Oak," "Royal Alfred," "Ocean Triumph," and "Caledonia," 4,045 tons.

g, the "Royal Sovereign," 5-turreted vessel, 3,765 tons.

h, the "Prince Albert," 6-turreted vessel, 2,529 tons.

i, a two-shield ship of 1,385 tons.

j, the "Enterprise," 990 tons.

k, the "Favorite," 2,186 tons.

The lower portion of the figure is a midship section of a British iron-clad ship of 1,385 tons, carrying two of the shields as adapted by Captain Coles of the British service. He was unfortunately drowned in the "Captain," which capsized off Cape Finisterre. The turret is shown as rotating on a central axis, and a circular system of anti-friction rollers. The conical portion only of the shield is exposed above deck, and the bulwarks are made hinging, so as to be thrown down when in action. The ribs, floors, iron-plating, and backing are also clearly shown.

The "Glatton," a modified monitor on Captain Coles's plan, was subjected to experimental firing by the British government to determine whether, by the impact of a 600-pound shot propelled by a 12-inch rifled gun, this turret could be jammed or prevented from working. There was also to be ascertained the probable damage that might be caused to the guns and other interior fittings of the turret.

The armor-plating of the latter, against which the shot was to be thrown, consisted of, first, one rolled covering of iron fifteen inches in thickness, disposed in two tiers, and secured to the backing and inner skin by bolts. Behind this armor-plating there is fourteen inches of teak, then an inner skin formed of two ¾ inch iron plates.

The gun used was one of the 25-ton 12-inch muzzle-loading Fraser guns, made at the Woolwich Arsenal. The projectiles selected were the Palliser 600-pound shot, solid and chill-headed, and the powder charge was 85 pounds large pebble. The vessel carrying the gun, the "Hotspur," was moored at a distance of 200 yards from and on nearly

Digitized by Google

a parallel line with the "Glatton." In the turret of the latter, a kid, a rabbit, and a fat hen were placed to try the effects of concussion.

The first shot which struck, took the turret armor in its weakest part, in the center of the turret-wall, upon a bolt-head and upon the lower edge of the upper 14-inch armor-plate. It lifted the upper plate until its lower edge was separated from the upper edge of the lower plate to a distance of 2½ inches, the upper edge of the lower plate, where the shot penetrated, being depressed nearly one inch by the sheer downward force of the shot.

The fracture extended upward from the plate's lower edge in a three-quarter-circle form, measuring 17 inches vertically and nearly 20 inches along the plate's edge. Inside the turret, the inner end of the bolt struck by the shot was found to have driven in and fractured the inner skin or iron lining, its nut breaking off and lodging upon one of the trunnions of the starboard gun.

The depth of penetration was 15 inches. Still, with all the immense striking force of the shot, estimated at a little over 6,100 tons, there was no through penetration, and the turret was found to revolve with the same facility as before the shot was fired. None of the gun fittings or gear were injured in any way. The kid, the rabbit, and the hen looked dazed, but they had sustained no other injury.

The German navy has the following iron-clads: "King William," 345 feet long, 58½ feet beam, covered with 8-inch iron-plates and 20 inches of elastic wood; it has 23 guns. "Prince Frederick Charles," 282½ feet long, 52⅔ feet beam, protected by 5 inches of iron and 15 inches of elastic wood cushioning; carries 16 guns. "Crownprince" is 277⅔ feet long, 48½ feet beam, covered with 4½ to 5 inches of iron and 10 inches of elastic cushioning; bears 16 guns. "Arminius" is 194 feet long, 35 feet beam, covered with 4½ inches of iron and 9 inches of cushioning; bears 4 guns. "Prince Adalbert" is 154 feet long, has 4-inch iron-plates, 8 inches of cushion, and carries 3 guns. The last two ships are monitors. The guns are all of heavy caliber.

The Russian sea-going turret ship "Peter the Great" is 329 feet 8 inches length between perpendiculars. Her greatest outside breadth is 63 feet. The builders' measurement is 5,352 tons, and the displacement, with coal, stores, and water in boilers, will be 9,665 tons, at a mean draft of 23 feet 9 inches. The plates on the ship's sides and on the raised building amidships vary from 12 to 14 inches, and the armor-plate protects the ship to a depth of 6 feet below the water-line. The vessel has no spur, but the upright stem is heavily plated and of enormous strength. The ship has two large turrets, which are plated with 16 inches of iron in two thicknesses of 14 and 2 inches. She has no masts, but depends entirely on her compound engines, which were built at St. Petersburg. Each engine is of 700 horse-power, and connected with 2 four-bladed screws. There are 12 boilers, which will require at full speed 132 tons of coal in 24 hours; and at this rate of consumption the engines will work at 10,000 effective horse-power, and the ship will be driven at 14½ knots speed per hour. If the engines are worked at the second grade of expansion, she will have coal for 17 days, steaming 12½ to 13 knots per hour.

With the single exception of the teak-wood backing, all the materials of the ship, engines, and armament were produced in Russia, by Russian workmen.

A round vessel invented by the Russian Admiral Popoff is 100 feet in diameter, plated with 9 inches of iron, and propelled by six screws on the part which may, by courtesy, be called the stern. A turret amidships carries two guns, which are fired *en barbette*. Below the water-line the vessel is divided into a large number of water-tight compartments.

I'ron, Cor'ru-ga-ted. Corrugated iron is used in many structures, — houses, sheds, cars, carriages, boats, tanks, etc.

As a covering for buildings it was first used as a roof for the Eastern Counties Railway Station at the London terminus, 1840. The plan is rectangular, with three aisles 230 feet long. The middle aisle 36½ feet wide, the side aisles 20½ feet. The iron is No. 16 wire gage, $\frac{1}{16}$th of an inch. The curve of the arch is at right angles to the corrugation. The sheets are riveted together in the direction of their length. The water follows the curves of corrugation to the gutters, which lead it to the posts; these are hollow, and conduct it to drains beneath the pavement.

Corrugated iron is in extensive use for buildings in countries deficient in wood, especially in some of the English colonies in the southern hemisphere;
